NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

THE BIGGER ISSUE

Well, here it is, your first giant sized issue of a ham magazine. You might as well be enthusiastic about it because this is the way it is going to be. To help you convert over we have the bookcase conversion project on the next page . . . thanks to Marsha Kay Gilger for the drawing.

Readers want to know why the large format. A reasonable question.

It all started when *QST* announced that starting with January they were going to go to the large size magazine, citing paper savings as a reason. I cited that as patent nonsense since more paper does not yet cost less, but I have the feeling that no one was paying much attention to me. I get that feeling a lot.

With just one magazine in the new size we might have held the fort, particularly since we tried as hard as we could to think up advantages to the readers in the new size and could come up with nothing. Then *CQ* and *HR* announced they were going large format. Oh, oh . . . this meant that many ads would be made up in the large size. It costs a lot to make up ads and few would be made in two sizes, which left no choice but to be dragged kicking and screaming into the large format.

It will not be news to readers that those advertisers are paying for your magazine . . . the ads pay the printing and paper bill as well as the generous payments to authors for articles. Subscription income pays for keeping records and mailing the issues and not much else. Of course without a lot of subscribers you don't get ads.

Once we decided to go big we figured what the heck, why not do it first? So here we are. Of course we had to cram all the November and December articles in one issue to get 1975 out of the way last month. Even though the last issue was double sized and had two months listed on the cover, it will still only count as one toward subscriptions. Merry Christmas.

NAME CHANGE

Got a letter from WB4SLO, Ñenad S. Downing (note the NSD there), claiming to be a *CQ* fan (I knew he was pulling me leg right there) and to be irritated by Wayne Green (you have to be dead from the neck up if I don't get to you). Then he goes on to praise the magazine outrageously . . . the articles and even the beneficence of ads. I can read letters like that all day. But that Nenad S. Downing began to percolate through . . . hmm . . . now, with a small change to Nayne, the middle initial is there already, stands for Sanger . . . I haven't used it much because my father goes by that name . . . and you can see how things perk up through . . . to Nayne S. Dreen. Heh.

The Candy Company seems to be getting closer and closer to making it possible for me to achieve the goal of many years . . . W1NSD. I'm so used to using W2NSD portable that I have an awful time just saying W2NSD when I operate from the Brooklyn shack. When I moved to New Ham Shire thirteen years ago, Candy suggested I hold tight, that rule changes would be along so I could get W1NSD and not have to settle for WA1EJU. Things move slowly in Washington, but one of these days . . . one of these days. . . Then all I'll have to do is wait for Candy to process the application . . . will I live that long? In the meanwhile I'll have to mull over that Nayne S. Dreen bit.

OTTAWA

The Radio Society of Ontario pulled off a first rate hamfest in October, with almost 900 registered in attendance and a nice bunch of exhibits, prizes and talks. The dinner was fantastic . . . 636 banqueted in one enormous room . . . and the food was excellent, quite a surprise to any regular banquet eater . . . roast beef, shrimp, black forest cake, the works. Congratulations are due to the group of hard workers that made it possible.

ARRL ELECTION

One of the California club newsletters had a good deal of info on a contest for Director between Doc Gmelin and Bill Eitel. I hated to see amateurs faced with a choice there as both are fine men . . . Doc has been at the ARRL Director biz for years and knows his way around . . . he is a tremendously likeable bouncy guy with a fantastic sense of humor and a bright inquiring mind.

Bill Eitel, recently retired from Eimac, by far our foremost manufacturer of power tubes for hams, has something that is extremely valuable for the League . . . industry background and knowhow. Bill knows everyone and is liked by everyone . . . he's been an enthusiastic League supporter for what seems like 50 years . . . he's been in the background of many of the better things that the League has done, such as the election of Herbert Hoover, Jr., as President of the League, a feather in the cap for amateur radio.

The ARRL bylaw which prohibits active ham industry people from being considered for elective positions has kept out some very fine men in the past . . . men with a deep interest in promoting amateur radio, not just their products . . . men like Herb Johnson of Atlas (the chap who started Swan!), Andy Andrews of Hy-Gain, etc. Bill Eitel would have made a very valuable Director years ago if the bylaws had permitted it and the League could only have gained from the association.

In this case, whichever way the election goes the ARRL will do well, so it is indeed painful to know that also, whichever way it goes, the ARRL will *lose* a good man.

TOY OR TOOL?

Topic number one, the "restructuring" of amateur radio, has generated a lot of heat . . . not an awful lot of light. Perhaps we can better consider the many possibilities if we go back to basics and start from there rather than trying to fathom the impact of new license classes on our own operations.

There are some fairly well defined guidelines as to the purposes of amateur radio . . . these are set out in not too clear form in 97.1 of the regulations. The rules state that amateur radio is to provide emergency communications, advance the communications art, provide a source of technically skilled people and provide international good will.

While it's true that older folk who get into amateur radio can help with the emergencies and good will, we would be less than honest if we didn't admit that the pool of technically trained people and advancement of the art doesn't refer largely to getting youngsters into amateur radio, not old timers. Thus it would seem to me that there is some logic to having our rules favor attracting young blood.

The proposed Communicator license was the major reason for the whole restructuring bit, so let's just mull over what we might or might not be able to accomplish with such a ticket. As I get the scene, the Communicator license is supposed to be a sort of half way bridge to get CBers into amateur radio. There appear to

be two main reasons for wanting CBers in amateur radio . . . hams feel a need for the hobby to grow and just don't know where else to turn for blood . . . and industry sees billions of dollars of sales if CBers can be encouraged to move to a new band or two. I'm afraid that the latter is more the moving excuse for what has happened so far.

Which brings me to a rather basic question . . . will we find in CBers this large group of teenagers that are what we need for amateur radio? My experiences on CB are certainly not encouraging in this direction.

The records show that roughly half of the newly licensed amateurs are either 15 or 16 years old, too young to get CB licenses. It looks to me as if we're planning on fishing in the wrong lake for the trout we want. I think that the ham clubs are on the right track . . . they're out there beating the bushes in the high schools for prospective hams, not flagging down truckers.

If we're out to find matured voices to fill up our empty repeaters, then Communicatorizing CBers is a good answer. If we want to really get growth . . . to bring some real money into ham manufacturing instead of keeping it almost as a hobby as it is today . . . the CBers are the way to go. Who knows, the ham manufacturers might get powerful enough to get a voice in the EIA and then we might be able to throw off the FCC entirely as the CBers have.

Amateur radio has a long history of inventing and pioneering and I think we all want to keep this alive . . . all we have to do is be sure of how to do it and make our voice heard above the tinkle of the coins in the till. I think that the ham clubs with good working license classes are going in the right direction . . . and I'm not convinced that a rubber stamp ham ticket is right, even though it could mean billions of dollars to industry.

CB IN PERSPECTIVE

Putting down CB is in many cases more an indication of insecurity on our part than anything else. CB has changed a lot in the last couple of years. The sunspots have died down and there is little DXing these days . . . a factor which has taken the steam out of super high power stations. The laws against amplifiers are beginning to be felt too . . . they are quite difficult to get in many areas.

With the enormous influx of trucks on the CB channels and the reduction in DXing, things have calmed down a lot. Bad language is the exception in most areas . . . it's a lot different talking to someone a thousand miles away and a neighbor.

It is time to give CB its due . . . amateur radio can't come close to CB as far as keeping track of traffic conditions. If you want to be able to avoid tieups you will be listening to channel 19, not your local repeater. If you come across an accident and want to call the police you may be able to do it through the repeater . . . but chances are you'll get excellent service on CB via a nearby base station. The CBer has the advantage of being nearby, not 25 miles away in another town, like the repeater. Argue with me, if you like, but if we really want to help in emergencies we need both amateur radio and CB in our cars, then we can pick the best one for the problem at hand.

Perhaps it is time to accept CB for what it is today, a relatively effective communications medium for anyone with a hundred dollars to spare. Considering that it is just about totally without rule enforcement, it is doing amazingly well. I wouldn't be without a pair of ears on channel 19 on any long trip myself.

COMMISSIONER LEE SPEAKS

Thanks KØBIY for the newspaper clipping quoting FCC Commissioner Lee as saying that he thought the best solution to the CB problem was no regulation at all . . . "I lean towards saying, 'Let's forget them.' " Lee pointed out that the actual enforcement of the regulations is miniscule. "About half a dozen" violators of CB regulations have been fined in the last year. "They're hard to catch, and when we catch them the Department of Justice doesn't want to prosecute."

ASPEN?

Hey . . . do you like to ski? How'd you like to get together with a bunch of us in January for some skiing . . . some fantastic meals . . . and a whole lot of ham talk?

About ten years ago I got conned into learning to ski. That turned out to be one of the better things that has happened to me in this lifetime . . . I've enjoyed skiing much more than I could ever tell you. After a few weeks of thrashing about on one of the local mountains, Kayla Bloom WØHJL, of Denver, talked me into stopping off in Colorado for a week at Aspen. In addition to getting to know Kayla and as a result signing her on to be editor of *73*, I found three things which just about blew my mind . . . the skiing at Aspen, the ski instruction at Aspen, and the amazing restaurants.

I arrived there an utter novice skier. Within one week they had me plunging down their most expert trails and ready to fearlessly tackle just about anything. They seem to have somehow managed to corner the world market on expert ski instructors. Since that time I've been out there twice more and both times my skiing improved tremendously.

With four big mountains to ski, they have something for everyone. I've skied most of the trails, but my preference is Buttermilk and Tiehack mountains. It seems to snow a few inches every night, resulting in beautiful powder for the early risers.

Restaurants. I think there are more superb restaurants in Aspen than any other single town I've visited . . . including New York. For instance, there may be one or two Mexican restaurants in San Antonio to rival Aspen, but not in New York.

On many weekends last winter groups of skiing hams would attack the mountains of New Hampshire, HTs at the ready. It's a lot of fun mixing the two interests. We would keep in touch with each other as we went up and down the lifts and slopes, usually on 52 direct. When some of the fellows went to other ski areas we would work them through a repeater and keep in touch.

It looks as if at least five or six of us from the Boston area will be flying out to Aspen, HTs in hand, for a week of skiing . . . January 3-10th. We'll be having a great time. Some are good skiers, some are just beginners. Steve Murray K1KEC, one of the New England repeater coordinators, just got on skis last winter for the first time . . . he'll be there. Chuck Martin WA1KPS, the chap who runs Tufts Radio, the largest ham dealer in New England, will be there. Chuck had done quite a bit of cross country skiing, but just got started on downhill last season . . . and he's a terror already. Two nicer guys you'll never meet.

Chuck threatened to bring a repeater, but Aspen is so small that it wouldn't be of any real use. We'll do fine with 52 direct there.

If you'd like to come along and join the fun . . . ski with us . . . get around

Son of a Gun! The Noble Breed!

It was raining last week and in seeking shelter we ran across one of the local QRPers. There was that lost expression on his face. "I am worried," he said. "I know that Glorioso is coming up and I need that one and Juan de Nova is on right now and I need that one. I worry about them every night and I am losing sleep over them. It is really a problem. A real problem."

We thought about this for a moment and took a chance at the reassurance angle. "You will work them," we promised the QRPer. "Sooner or later you will work them. That's for sure!"

The QRPer did think about this for a bit but was right back. "But when?" he asked. "When will I work them? And after I work them, what about those new countries that are sure to come? How do I know I will be able to catch them? How can I keep from worrying about those ones? You must see the problems I have, don't you?"

Son of a Gun!! What could we say? For there is a joy in anxiety and solace in worry. And for some there will never be a happy day without its worry. For when you have worked everything, what will there be to look forward to?

* * * * *

We were doing some road work over the ridges last week, getting set for the CQ WW DX Test. And we ran into one of the locals who has toiled these many years on various things such as traffic nets, rag chew nets, state-of-the-art things and stuff like that. "How's DX?" this one asked politely, and we had to admit that it was thriving. "What are you working these days?" he asked, and we had to admit that we were working the world every morning and evening. "Anything new?" he persisted, and we had to admit that after working everything we were now working everything backwards and with our left foot as an added challenge.

The Ordinary One thought about this for awhile and finally came back with a bit more. "You know something?" he said. "A few years back I went to the Pacific Division meeting and one of the fellows there said that DXers were the top of the amateur crop . . . and that they knew it. I really think that he was right. I really do."

Son of a Gun, what could one say to something like that – though one must expect such things. When you are Number One . . . when you stand like an unattainable model to those other types, one must realize that DXers are unique. So all we could say was, "Heck, I always thought that everyone knew that already."

DXers are the Noble Breed!! Would any true-blue one admit otherwise?

A Good Deal for Dummies

Early one morning I was watching the tube. They had a program on telling about communities who got Federal money and some good action by banding together and legislating what they needed.

I got to wondering if we hams couldn't do something like that. No big national organization was telling these communities what they needed. The ideas came from the people who were going to be affected by the changes.

The program told about a beautiful wooded area which was just sitting there. It was owned in the main by people outside the area. Somebody got the idea that, since the town was growing a bit, the woods would make a nice park. Soon other people became interested. They got together and made a plan. Then they talked to the land owners and got their consent. Next they got the plan approved by the community government. And, what do you know? They got the park plus some Federal money to spend for roads, picnic tables, swings and things.

Okay, we hams have a natural resource sitting there. It's owned by everybody. We would like to park there now and then. We find it a nice place to come and visit. Maybe it's 80 meter CW, 160 phone or 2 meter teletype, or maybe even 440 fast scan TV.

A long time ago someone got the idea that these are really fine natural resources, and, fortunately, some of the good spots got reserved for those who took the trouble to equip themselves to use them.

Now and again hoodlums come along and garbage up those beautiful spots, but nature has a forgiving way about her, and the spots are clean again for the next batch of humans.

Here is where we ought to shake ourselves out of our lethargy. Right now, instead of being lucky people, we hams are getting the business. Instead of getting Federal money to beautify our part of the natural resource, our leaders are about to call in the Feds to cram us into smaller segments, compartmentalize us, and dump garbage all over us. And many of us dummies think we're getting a good deal.

Called to (Varl)arms

Mementos of Solomon Islands days.

In 1940, Henry Rice W9YZH, in St. Louis, designed a variable frequency oscillator, which James Millen Co. put on the market commercially as the Variarm. During WW II, an enlistee named Harry Turner W9YZE, from the same metropolitan area, loaded up a Variarm and went to serve Uncle Sam in the Solomon Islands.

Harry was — is — a telegrapher of note, and presently got his go at winning the war with his skills.

It seems Harry and his gang occupied one end of an island while the Japanese camped at the other end. Somewhere in the vicinity lived an assortment of headhunters and a missionary.

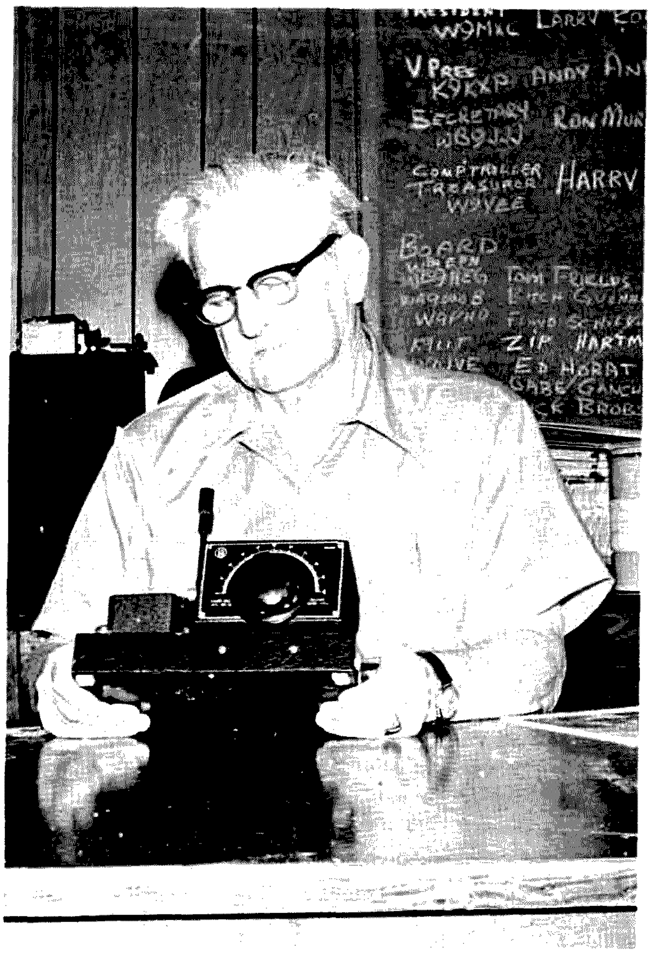
The Japanese gave trouble by night, wherefore Harry's gang felt constrained to call in the bombers for a little softening action. The process involved getting on the radio and calling for help. The Japanese, being largely educated at UCLA, as the saying goes, weren't ignorant of our communications, and, hearing same, would immediately join in the transmission with spurious signals of their own ("jamming").

That's where the Variarm and Harry's "fist" came in. He'd attach an antenna directly to the output of the Variarm and start pounding his key. He could put on a good show, too: He'd been clocked in training at 35 wpm on a straight key. The Japs, sure they'd found the hot line, began their jamming, and Harry started pulling down that Variarm to change the frequency gradually. The Japanese credulously followed the drifting, seemingly unstable rig to the limits of its variable arm's play. At that point, Harry would punch the operator next to him, who would use the original frequency to call for help. Wonder just what the Japanese thought next day when they were on the receiving end of U.S. bombs?

To regress just a moment, going back to Harry's CW proficiency: In 1964, Harry applied to the Signal Corps for some certification of his code speed record and got it. When in 1966 the Red Chinese claimed a girl of theirs had set a world record at 30 wpm, Harry trotted out his certificate. The Chinese claim was based on a "secret" speed run, excused as being so to avoid distracting disturbances that could have upset her concentration. Did it even take place? Who knows, but Harry's feat was not only a matter of government record, but personally witnessed by a roomful of onlookers, including the commanding general, Ben Lear. Harry says he handled code under "business" conditions and learned to concentrate accordingly.

Harry Turner was released from the Army in 1945. The Egyptian Radio Club (W9AIU) had been founded in 1929 and wasn't unknown before Harry's influence began to show in 1950; ERC had won the ARRL's Field Day contest three years in a row, 1937-39. Harry was soon elected treasurer of the Granite City, Ill., club and has held that post ever since. He's retired now from his variety of livings, having been railroad telegrapher and printer as well as having worked for 23 years in a paper mill. For a time he was editor-secretary-treasurer of the QRK low power radio club. Today he's usually around the club's 16-76 repeater, and every Thursday night sees him at the clubhouse by the Mississippi's Chain of Rocks Canal.

Harrison L. Church WØKX/9
Box 126
Lebanon IL 62254



Harry Turner W9YZE looks over the Millen Variarm VFO, like the one with which he decoyed Japanese in WW II. The rod sticking up is the "variarm" that turned the trick on this rig, with Harry providing the "fist."

What This Country Does Not Need

The eternal problem of acronyms is that they are great if you recognize them, but confusing when you do not. OTP stands for the Office of Telecommunications Policy, a White House Office – some feel it's another FCC . . . potentially.

The head of the OTP was asking the House Appropriations Committee recently for an increase in its budget, it being noted that the OTP is currently a "way station" to a comprehensive federal agency handling communications matters in the future. However, it was acknowledged that the time was not ripe for a stronger office outside the Executive Office of the President. OTP was asking for $8.9 million to run the 48-man office for the next year. The FCC got a much stronger going-over when it came up to discuss its budget, asking for $49.8 to run that agency in the coming fiscal year. The OTP has been heard in the past urging the FCC to faster action for the CB Service. As one astute observer has said: "What this country does not need is two FCCs . . . or maybe even one OTP!!"

A recent item in the newspapers called attention to a manpower crisis in radio spectrum management. John Eger, Acting Director of the Office of Telecommunications Policy, declared a "state of emergency" and announced a government-wide career development program to rectify the situation.

With the next international general frequency conference scheduled for 1979, worldwide allocations will be established through the year 2000 – and there lies the problem. Assignments of spectrum space are negotiated at these international meetings and the resulting agreements supercede national law. According to a study made at OTP's request, more than 57 per cent of the U.S. agencies' experienced and conference-tested negotiators will have retired by 1979 – leaving only 15 top-level experts to represent the United States. The study found that of the 194 individuals now involved in national-level agency activities for spectrum management, only 35 are principal managers with the negotiation, regulatory compliance, technical analysis and decision-making experience bearing on radio frequency management. Of that number, 20 are expected to retire before 1979.

According to a General Accounting Office report, such an impending personnel shortage could jeopardize the U.S. interests at the most critical international radio conference in 20 years, and could spell trouble for future users of the radio frequency spectrum.

For that reason the OTP has instituted the first government-wide career development program for the training and retention of the highly specialized personnel needed in spectrum management. "National and international concern mounts over the continued availability of spectrum space," the OTP said. "To respond to that concern it is necessary that an adequate investment be made in personnel development."

Jim Huffman's

What will be happening in amateur circles in January, 1986? We asked Hufco's WA7SCB, and here are his predictions:

The next ten years for amateur radio (and electronics in general) look to be the greatest ten years ever conceived by man. Improvements should come in two main areas to amateur radio: operations and equipment. As far as operating goes we foresee more and more hams joining the fraternity. Face it: The world is smarter nowadays and promises to be even smarter in the future. People in general are becoming more technically oriented. No one today hasn't at least heard of the computer, and most deal with computers every day. We even communicate with computers to pay our bills. This technological "brainwashing" of all mankind should prove to lessen people's fear of amateur radio. Twisting knobs, using a microphone, watching meters, and so on, are the so-called fears of amateur radio, but none poses as much of a psychological problem for the average man as it has in years gone by. And in ten years! All mankind will be ready to accept the possibility of communicating around the world via amateur radio.

The technological boom has also primed man's "escape" mechanism. He travels, he plays, he turns to drugs, all supposedly as his escape from the hard, cold technical world. And what better escape than amateur radio? Electric bills will never climb proportionately to gasoline bills. The average man can travel the world and never leave his cluster house, or condominium. Amateur radio offers him everything: the excitement of the DX contest, the enjoyment of the ragchew, or the unequalled pleasure of home construction. All this in ten years if we now realize the potential and spread the word that amateur radio is the greatest!

As far as pure technological advances in amateur radio go, look for computer controlled repeaters in the not too distant future. Look for computer controlled hamshacks next. Scanners that find an empty "slot" on the band. And new narrow bandwidth modulation systems that promise more hams per megacycle.

There are indeed paradoxes which will appear in the future. One involves complexity (sophistication) and lower cost; the other is complexity and simplicity. While one usually thinks of the more complex devices costing more, we are witnessing the opposite. More complex functions are being integrated to a simple chip and then mass produced, so that they cost less. And costs are going to have to go down in other ways (proportionately, of course, we will still have terrible inflation). Manufacturers will have to solve high labor costs to lower the prices proportionately, and manufacturers will! People should wise up in ten years, and start producing more. Look for per piece wages rather than hourly pay. A lot of people are using this already. The lazy worker earns a

visiting views from around the world

Here to Stay

It doesn't hurt once in awhile to do your own thinking. I was listening to an on-the-air round table discussion of the FCC Proposed Rule Making Docket No. 20282.

There seemed to be two types of comments. One type came from ARRL loyalists who thought we should go along with the proposals as modified by ARRL management. Then came the comments from the die-hard, independent thinkers who inquired into the reasons for wanting the changes made.

The reasons for the changes seem obscure. If the proposed changes are for operator skill upgrading, certainly the existing five classes of licenses offer a reasonably wide spectrum.

If the reasons for these changes are for opening up one more class, the codeless class, we certainly don't need all this mountain of paper just for that.

So just why are we undergoing this massive rule making exercise? I'm wondering why not to stir up the troops, but rather to inject the question, "Why?" Change is fine if it's necessary, but what is really necessary about the proposed changes?

We are still, when the dust clears, going to plug in on the power line or battery, hook something to an antenna for the purpose of poking out a signal and hoping to get one back. We want to modulate that signal by some scheme (exotic, sophisticated, or otherwise). We're still going to be the same clever (or dumb) human beings at opposite ends, doing it all for the pleasure we get out of it. That part of it won't change, I hope.

So what is changing? Really, what does Docket 20282 gain for us? We are going through a huge paper exercise for a net gain of promises. Maybe we'll get a new 10 MHz segment – maybe. Plus we'll get some new guys who claim they CAN'T learn the code.

It was reported recently that doctors are getting disenchanted with the American Medical Association, the AMA, because it's too costly for what they get, and they don't look to it for leadership any more.

I belong to the ARRL. I support it where I can, but I'm disenchanted with some of the direction the ARRL gives. These thoughts might point the way to some changes not so much to the FCC Rules, but to the direction we are being led.

CW is outmoded. Who wants it? Okay, think that way. Maybe it doesn't happen very often, but once in a great while knowledge of CW turns out to be of great help.

If I were in trouble a long way from home, I'd surely try a CW contact on one of the Novice bands. The guy on the other end might be just a kid, and his CW might be slow, but I'd trust him to get my message.

No, we don't *need* to know CW once we pass the test (except at license renewal time), and I don't care if the FCC wants to grant licenses to those who CAN'T learn the code. But I don't wish to abandon CW. It's like another language. I want to keep it alive.

CW transmitters are the easiest to build and to operate. Before the advent of SSB they were the most efficient in miles per Watt.

We have tremendously sophisticated methods of communication nowadays: tropo-scatter, satellite, microwave, computers talking to computers, scramblers, high-density multiplex, and much more. In spite of it all, CW is here to stay. Our "friends" across the seas seem quite sold on it.

Paul L. Schmidt W9IDP
PO Box 105
Bloomfield IN 47424

1986

lazy man's wage; the hard worker has no limit to his pay.

Paradox number two is even easier to see. Complexity vs. simplicity. While on the one hand things are getting more complex, they are getting simpler, too. Already the average ham can put together systems of sub-kits into his own custom designed equipment. Witness the kits from VHF Engineering, the International Crystal kits, our own digital kits. In ten years it will get even easier. And while digital subsystems are easier to interconnect now, look to the time when it will be just as easy to fabricate your own complex analog systems, like a sideband rig. The complexity of the rig will be a function of your basic knowledge and how much you want to spend. With all the complexity you can design in, the designing itself and the operation of the finished product will become simpler. It will be much easier to use a computer autotuned rig that automatically matches any piece of wire on any band and tunes itself to optimum at the flick of a bandswitch. And that is what I foresee in the next decade. Our present day broadband rigs with their inherent compromise designs will give way to computer tuned rigs that have the same one hand operation with far improved performance.

The next decade promises excitement, adventure, and challenge. I guarantee that, no matter what happens, we will all rise to meet the occasion. So start to stand up now. Learn about logic, computers, analog, design, and so on. Although you may only be able to possess a cursory knowledge of such a broad range of matters, that cursory knowledge will allow you to interface some powerful subsystems in the "simplicity" of the next decade!

LETTERS

I insist that you print ev

A NATURAL

A recent article submission to Wayne written by me was rejected (so don't quit writing if you are rejected), but his always appreciated comments have prompted this open letter to you – the VHF-UHF ham.

One of my suggestions in the article concerning more effective use of our higher bands was the use of voluntary channels. *Note,* I said totally voluntary. My suggestion was to use the following frequencies as listening posts, so that any activity whatever in the nature of an opening would not go unnoticed, much like the use of beacons: 50.125 MHz, 145.125 MHz, 220.125 MHz, 432.125 MHz, and 1296.125 MHz. There is no magic choice about the frequencies, and I will gladly listen to any and all contrary suggestions. It is just that the .125 remains the same on all bands, the MHz portion is in a part out of the CW and General only areas (so more should be able to use them), and (lastly) their proper use would also be a must.

Even if you hear no signals, try a call on these frequencies. If everyone could monitor the same place (as I do on 50.125 MHz), he could go ahead and work on the bench, etc., and monitor just like FM. If you do find action on .125, move up 5 to .130 and leave the .125 open again. When one first listens he will tune around a little, so he will still hear you. The next guys go to .135, etc. On CW or SSB this is plenty of spacing, and has led to much activity here in the Midwest that I'm sure I would have missed. About 15 of us have tried it for over a year now, and the activity *and* gentleman's agreement to move have worked out quite well. With groups like Smirk increasing VHF activity, a common looking place seems to be a natural to increase activity even more. Comments anyone?

PEA-SIZED

I have been racking my pea-sized brain for many years and have nearly short circuited every brain cell that I have (there are only three left, I think) in a futile effort to break the 1 wpm CW barrier. It breaks my heart to part with these hard earned dollars but I will make a sacrifice and ask you to please send me a complete set of those revolutionary code tapes for $14.95, and please hurry before I short out those last three brain cells.

Oh yes, seeing as how I have been stumbling through all that technical jargon for years and years with the only result being a shorted out pair of ears, you had better send me a copy of the General Class study guide too, so that I can reserve one of my three brain cells for the technical bit. You will find one American Express compny money order to cover the whole smear. You see, I am so short on brain cells now that I can't even spell "company" correctly so please send the stuff fast before I completely short circuit and go up in a puff of smoke in an effort to duplicate the original "smoke test."

ENDURING

As life member no. 5 of your *73 Magazine*, I thought that you might be interested in a barn I came across here in Conn. I'm not sure if the farmer feels that he can endure the year 73 or the magazine.

Richard Johnston K1OJD
Simsbury CT

BACKGROUND

Just received my first issue of *73* (October), and would like to say how much I enjoyed it. I hadn't really seen the magazine before, as it isn't carried on any newsstands around here and the libraries don't get it. I subscribed on impulse and am glad I did. The format and content beat *CQ* and *QST*; the tone of the articles is sprightly and good-humored, yet informative. I commend you.

For those of us who haven't been reading for years, how about a little background info? Is the W. Sanger Green who does Ancient Aviator your father or some other relative? I found it quite enjoyable. Also, during the past few years, as I read the other ham publications, I ran across rather disparaging remarks about you and your publication(s). I am ordering a packet of back issues, but how about a retrospective look at whatever all that was about from your point of view, again for those of us who are new to the *73* circle?

Your comments and stand on advertisers who do not deliver as promised are a good thing and sorely needed. I've had trouble in that area myself, with hi-fi gear. Back in 1971 I ordered a tape deck from DEFA Electronics in New York, and it was only through the intervention of the New York State Attorney General's office and finally the Federal Trade Commission that they finally sent me a refund check just two weeks ago. (It hasn't cleared yet.) So keep up the good work in this area. As a helpful hint, let Wes Larsen (WN3ZHT), who wrote you about Trigger in the October issue, know that going to the Post Office to complain of mail fraud is a waste of time. The Postal Inspection Service does next to nothing about such things. Tell him to write the Consumer Protection Division of the Illinois State Attorney General's office and the Federal Trade Commission. Those agencies will try to *do* something, usually, while the USPS will send you a form letter stating that they don't think the mail fraud statutes were violated. I believe these laws are so peculiarly worded that most cases of what we would call fraud (failure to deliver, no refunds, shipping wrong items, etc.) are not included. The USPS, in conjunction with the Federal Trade Commission, did propose to broaden their protective stance (see *Federal Register*, March 8, 1974) but I don't know whether that ever was implemented.

Anyhow, glad to be in your group now.

William G. Martin
St. Louis MO

Thanks, William, for your letter. The Aviator series is being written by my father and seems to be very popular. Re the anti-73/WG stuff elsewhere . . . several factors are involved. If 73 was a failure they would ignore it, but it has been very difficult for

them to see 73 becoming the largest ham magazine, with the most ads, the most articles, etc. After some two generations as The Establishment, QST is taking it very hard. My outspoken editorials have not cemented friendships . . . the fact is that I have many admirers who appreciate my seeming radical viewpoint and many enemies who fear and resist the changes I bring about. My basic philosophy is that amateur radio is fun! One of the results of this fun, if it is not ham-strung (pardon), is a wealth of inventions, pioneering and new ideas. Even with the severe restrictions presently in force, which I would like to see removed, virtually every major breakthrough in modern communications has originated with amateur radio. While I am not at all sure what a man can do in this world to be worthy of the privilege of having lived, I have chosen the role of trying to help, in what small way I can, the rolling forward of progress via ham radio. Via 73 I try to encourage new developments, the growth of amateur radio in small countries, etc. My critics say I'm trying to make money from amateur radio, while those around me complain that I am ignoring the money end and getting into trouble as a result . . . witness the IRS problems. I don't know if that explains anything . . . and thanks for the word on dealing with frauds – Wayne.

BLACKSMITH TYPES

Just want to let you know that I enjoyed your Oct. 1975 issue very much. This issue was right up my alley, since I am not interested in VHF, repeaters, or any other phase of ham radio other than building. The articles in this issue are very desirable for us blacksmith types who aren't happy unless we can get dope on building something new. Sure would like to see a couple or three issues each year for us screwdriver mechanics. Also, how about another super jumbo king size surplus edition each year?

R. F. Herbig W6ME
Oceanside CA

YASME

The YASME Foundation is active again and is sponsoring once more the world-wide DXpedition of Lloyd (W6KG) and Iris (W6DOD) Colvin. The Colvins have already operated under 50 different calls and are now trying for 100. First stop will be VR1Z (15 Dec 1975) and then VR8B (1 Jan 1976). The latter call will count as a brand new DXCC country. Transmitting frequencies are:

CW: 3505, 7005, 14050, 21050, 28050. (Listening up 5 kHz or just inside General Class band.)

Phone: 3795, 7095, 14195, 21255, 28550. (Listening up 5 kHz or just inside General Class band.)

Donations to YASME (tax deductible) are requested but not required.

LESS INTIMIDATED

Just had to comment on Wm. Browning's article on logic circuits. AND, NAND, OR, NOR, etc., have stumped me for quite awhile. Now, however, I feel at least a little less afraid of them – or should I say intimidated by them. Thanks much.

J. Hutchinson
Verona NJ

THE SALEM 50

Here are a couple of photos taken on opening night of the Novice course sponsored by the Salem Civil Defense Communications Team at Salem (NH) High School. The instructors are WA1HWE, WA1OAQ and W1PFA.

The total number taking the course is 50, with two or three people from one family in several cases.

Bill Loeffler W1PFA
Salem NH

GETTING OUT

I sent for tapes and a subscription to *73 Mag* a month ago! The tapes have been here OK – but no mag. I requested a current issue. Nothing has come. I do *not* need the mag now as I cannot get up to 13 wpm – so I can't pass the General. Since I only wanted to use voice, I am getting out of the whole thing. No more trying for me.

So – please cancel my subscription – immediately – and *return my $8.00* sent to you on Aug. 21, 1975. Thank you.

Fred Lichtgarn
Santa Barbara CA

It may be difficult to believe, but it takes about six weeks for a new subscription to get into a computer, be printed out, and sent to the printer for mailing . . . get mailed and reach a subscriber. We are working on shortening this . . . with our own computer . . . but that is a big deal . . . about $75,000 . . . it will take a few more months to get set up.

I have canceled your subscription . . . there is no way to stop an issue or two of the magazine going to you . . . my compliments . . .

Now, regarding your ham license . . . I am truly ashamed of you. I see little girls of ten getting their General licenses and here you are trying to tell me that a ten year old girl is better at sticking to something than you are.

Your letter is going to get a lot of use . . . I intend to hold it up as an excellent example of why it is important to have a code test for the license. If someone cares so little about getting a ham ticket that they won't even spend that little effort, there is no way that they can be worth anything to us.

It doesn't take brains to get a ham license . . . it doesn't take education . . . it doesn't take any talent . . . all it takes is some work and you are too lazy. We have hams who are so dumb they can just barely talk . . . so uneducated they can't write much more than their name . . . but they hang in there and get their ticket even if it takes them a year of hard work.

You only wanted to use voice . . .

well, that's about all I've used over the years, but there have been times when it has been important for me to know the code . . . it saved 85 lives once, believe it or not. Including mine.

Maybe I'm being harsh, but you sound suited to what I am hearing on CB where it takes nothing more than a reach in the pocketbook to get on the air and waste your time . . . and wait for death to eventually come along, having added little to the world. — Wayne.

LIKE NBC

Here is some information regarding continuing PR efforts in our area. I hope the information will be of interest to other hams, not only in regard to PR, but also in the use of microprocessors and terminals for support of their amateur activities.

Solid 2 meter communications combined with the world of computer technology to provide communications for the State Sanctioned Canoe Races at Milford, Michigan. Race progress from various checkpoint stations along the Huron River were relayed to Race Control via WR8AAA.

Race operations were tightly controlled by the base station in order to cut down on unnecessary transmissions as pertinent race information was being patched to the P.A. System.

Also, located at the base station was a computer video terminal which, combined with remote monitors, was used to format and display race progress to the spectators.

Thirteen members of the Milford Amateur Radio Club participated in the event through the courtesy of WR8AAA. The home brew video terminal was provided by W8JWQ, who normally uses it with an 8008 microprocessor system.

W8JWQ typing race information into his home brew video terminal during the Milford Canoe Races.

Response to the overall effort was very favorable, with many PR points being scored with city officials. For example, witness the following excerpt from the *Milford Times*: "Allen extends his thanks to the Milford Amateur Radio Club for providing superior communications services during the entire two day event. One racer said the local group's services were 'like those of NBC'."

John Moore W8JWQ
Milford MI

FREE PLEASURE

"FREE — one trip to Hawaii for 10 days." (One year from now it's just a memory.)

"FREE — a ticket to the Metropolitan Opera." (One year from now just a musical memory.)

"FREE — one year's subscription to *73*." (Send 3 year subscription and pay for two and get a free year of constant ham pleasure.)

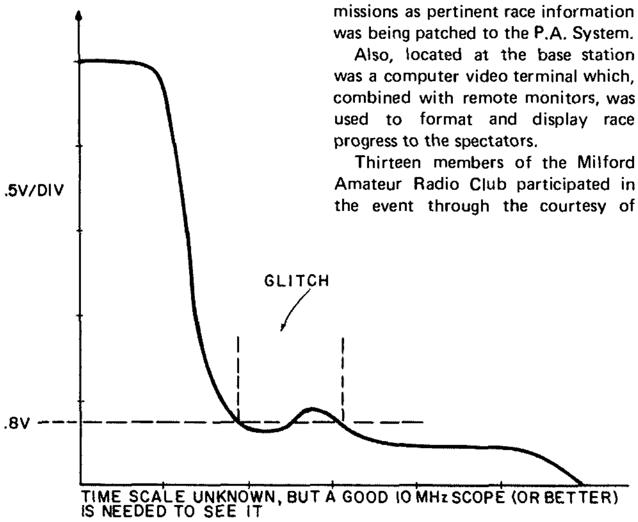
Enclosed please find my renewal and subscription for three years to *73*.

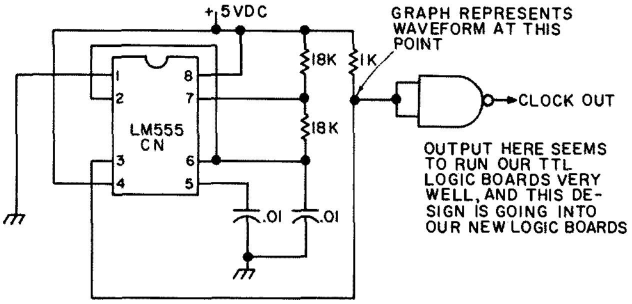
Syd Tymeson W3FL, WA1BXD
Takoma Park MD

GLITCH

We (at Collimation, Inc.) have found an interesting item you may wish to pass on to your readers of *73*. It seems that the 555 timers from National, Signetics and Raytheon (and perhaps others) have a glitch on the falling edge at about .8 V, which may cause some TTL devices to see two clock pulses where only one was intended. I have enclosed a diagram depicting the problem and the solution we use.

Joe Magee WA5ACA
Austin TX





LM555 clock glitch and corrective circuit. .8 V represents the lower boundary of the uncertainty area for TTL logic signals. A signal which hovers about that point may very easily cause several transitions in a TTL gate. 74174s seem most prone.

GREEN'S FAULT

Keep up the good work in *73*. I'm having a tough battle with the ARRL conservatives down here in Houston, Tex. According to them, "It's all Wayne Green's fault."

I wonder if all the repeater boys know who it was that made the 2 meter band what it is.

Herbert G. Robinson K5URX
League City TX

CRAZY TAPE

I just got word that I finally passed the code test to get my Advanced license and upgrade from a Technician. Since I just graduated from Purdue in Electrical Engineering, passing the written exams was a snap, but the code was a real snag. I got your 14 wpm backbreaker last spring, after I had already flunked the code once. So, once I got the tape and read how great it was, I figured that all I would have to do is listen to it and breeze through. Much to my surprise, I proceeded to flunk the test twice in six weeks. I was pretty frustrated, and just hung the whole thing up for the summer. I got the bug again towards the end of August, and I finally discovered how to use the crazy tape. I found out that I not only had to copy the tape, but copy it *easily*, almost unconsciously, for 20-30 minutes at a time. When I got so that I could talk to my wife and still copy easily, I knew I was ready. I went into the exam room and copied about two minutes of the tape, corrected a couple of mistakes and copied the last two minutes correctly. The difference was how hard I worked on the tape beforehand.

I'll be in Africa next year, and hope to see you all in the pileups!

Joe Ely WB9PVL
Lafayette IN

WHITE ELEPHANT

Your editorial musings about timers sent me to my new copy of Part 97 to do some checking, and sure enough, there is no legal requirement for a timer on either the input or the output of the repeater. Part 97.88d does say that there must be a timer on the CONTROL SYSTEM so that in the event of failure the repeater is taken off the air. Where this great misconception got started I do not know. I am a control station with one of the busiest repeaters in the New York City area, WR2ACD, an open machine with a weekly user list of about 500-600 steady people. With the transients it goes to about 650 a week. In this case, with the repeater on the air 24 hours a day and getting steady use for about 22 of those hours, a timer is needed to keep rag chewers at bay during "traffic hours," those hours when the commuters take over. At other times, however, rag chewing is usually the mode of operation, and in this case, the timer becomes a white elephant.

As I travel throughout the area I am amazed at the number of machines that have timers and, frequently, not many users. Again, I suspect the great misconception. It is certainly an unnecessary inconvenience. Man does not talk in two to three minute segments with a three second pause. It is needed on the machines with large populations, but why with the less populated machines? Having dispelled the "because it's law" myth, maybe more repeater owner/operators will reconsider their stand on the issue. I think it would make operating a bit more natural. Of course the timer on the control system, be it wireline or 220 MHz and above, must remain in force to keep the uncontrolled repeater off the air.

MSI

As a subscriber to your wonderful mag, I would like to tell your readers about a possible channel of amateur publicity.

For the Amateur Radio Club looking for a new Public Relations medium, I have one to suggest. The medium is the MSI program found on many CATV systems. MSI is a mechanized presentation of information like time, wx and news. Usually seen on a non-broadcast channel, MSI may be coupled with a 35 mm slide projector. The slides on the projector can be pictures of local buildings, advertising, and public service messages. The slides flash on the screen for usually 15 seconds and then the MSI unit switches back to the wx, time, news, etc.

Your club can have a Public Service Announcement on the MSI cable channel announcing when the

Ed Pillar W2KPG, receiving test pattern from W2TRP on LIMARC ATV Technical Net.

SPURRING ATV

Despite the advice of some engineers that it could not be done because of an internal decoupling network, electronics engineer Irwin Dresner W2TRP, of Syosset, L.I. (NY), succeeded in video modulating a Motorola 440 MHz MHW-710 power module with a full 4.5 MHz bandwidth TV signal. His fifteen Watt output signal, coming from a palm-sized solid state TV transmitter, was received by K2RIW, W2KPQ and WA2APJ on September 2nd during the weekly meeting of the LIMARC ATV Technical Net. W2TRP will make full disclosure of his techniques to industry and amateur radio in the hopes of spurring ATV activity.

The ATV Net operates on the LIMARC 146.85 MHz (output) repeater and transmits video on a simplex basis on 439.25 MHz. Signals are receivable throughout the metropolitan New York area each Monday evening from 10 to 11 pm.

I'm enclosing some photos of some LIMARC ATV Technical Net members which you might find interesting.

Back In The Air Service

After the two crashes I told you about last month, I finally got the message about flying the types of civil airplanes that were available at that time. The luck that was with me in the Lindenhurst, Long Island crash, where the ground that came up and hit us happened to be in a field where a fire department was drilling, couldn't be expected to continue. If I wanted to keep on flying, the answer was better equipment. In those days it was either flying mail or getting extended active duty in the Air Service. I opted for the Air Service with the idea that, if I found it was the kind of life Cleo and I wanted, I would take the examination for a regular commission. So I applied for six months active duty. In May 1925 I received orders to report at Langley Field, Virginia for six months active duty from 1 July.

For $50 I bought a model T Ford sedan that I had taken in trade on a new Hupmobile. It was in good mechanical condition so I just piled

> **The ground that came up and hit us happened to be in a field where a fire department was drilling . . .**

our luggage in and drove to Langley. When I reported in I was assigned a house that I later found was supposed to be a major's quarters – and I was only a first lieutenant. Too good to be true. A few days later Cleo and Wayne arrived by train.

I was assigned to the 11th Bombardment Squadron. They had one hangar and seven active Martin bombers, plus one in the back of the hangar that was being cannibalized to help keep the rest in the air, and another that was so near the junk pile that, when it was in the air, its tail wagged like that of a dog. These NBS-1s were stick and wire jobs that were built during WW1. They were biplanes equipped with two Liberty engines.

My first flight in one of these bombers was on the 4th of July when, as co-pilot to Capt. Early Duncan, the Squadron commander, we lead a seven ship, three hour, formation flight to Richmond and returned. In a few days I was checked out in the bombers. The NACA (National Advisory Committee for Aeronautics) had a hangar on the field for their experimental planes. Tom Carrol, a very good friend of mine, was their chief test pilot and through his good graces I was able to borrow various types of planes, most of them single seaters, such as Spads, SE5s, Fokker V11s and Vought VE7s, to have fun in. I reciprocated by checking Tom out in Martins.

During my six months tour at Langley I made some 52 cross country flights in DHs and Martins. Some were eventful (mostly due to the very sketchy weather information available), others just pushing the ships along: Bombers cruising at about 70 mph and DHs at about 85 if you weren't bucking a wind. The ground doesn't go by very fast unless you are right down on the tree tops. Some of the more important trips I made were to Bolling Field at Anacostia, D.C., when it was my turn to bring back the 5 gallon can of grain alcohol that was needed each week to keep the "Anonymous Alcoholics" on the "prohibition dry" post properly lubricated. It made about ten gallons of gin, but then there were a lot of thirsty subscribers on the post. If Wayne can remember (he was three years old at the time) he can attest to the gin's potency, as he somehow got hold of a glass with a little in it and choked it down. He was reeling before Cleo realized what had happened.

Around the first of August, Capt. Duncan was transferred to the Command and General Staff School at Fort Leavenworth. I was quite flattered when Major (Tubby) Westover asked me if I would take over command of the 11th Squadron until Lt. Ken Walker arrived in December to be its regular C.O. Westover was Commandant of the Field so I said "yes" even though I knew it meant a great deal of responsibility as well as the loss of what otherwise would be leisure time. So, after an audit of the squadron fund, I took over Capt. Duncan's cigarette pock-marked desk.

The personnel of the 11th consisted of four reserve lieutenants, on active duty like myself, and 124 enlisted men. I inherited an excellent team of noncommissioned officers: a first sergeant who, with the squadron clerk, ably handled the mass of squadron paperwork, daily work assignments, discipline, etc; and a supply sergeant who not only knew his way around Langley but had excellent connections at several other Air Service posts, as well as nearby Fortress Monroe and Camp Eustace. He could get almost anything needed in record time. No questions asked. The mess sergeant seemed to be "grouse" (grumble) proof, which is saying a lot. He had two cooks and two or three KPs (kitchen police) to help, and had to operate on a very

> **NCOs can teach a young lieutenant much more about running a squadron than any officer's school . . .**

tight budget. Our hangar crew of mechanics and specialists and their maintenance shops were bossed by a master sergeant who had been in the service for about 18 years and was "bucking" for a 20 year retirement. Very few things escaped his notice, and when he had inspected a ship and signed it out to the line you could be sure that it was airworthy. These NCOs can teach a young lieutenant much more about running a squadron than any officer's training school. However, a squadron C.O. is needed to oversee and coordinate the work of the several jealously guarded squadron domains.

The administrative procedures I set up seemed to work pretty well. The four lieutenants and I took turns at standing the reveille roll call every morning. Two mornings a week I had a short staff meeting attended by the officers and the first, supply, mess and hangar master sergeants, to discuss and settle any squadron problems and also to finalize the next day's operations schedules. The other four mornings a week I was in my office right after barracks inspection to sign papers and to discuss the problems of any of the men. One of the officers or myself had to be available on the post at all times day and night.

About the end of September a major arrived at Langley with his family, so we were moved to a house in the lighter than air section of the field. About a mile from my hangar.

I'll get back into the air again next month with a forced landing or so. Also a tragedy.

AMSAT

Joe Kasser G3ZCZ

At the AMSAT general meeting, the four directors whose terms of office had expired were reelected. The AMSAT board now comprises seven persons: Perry Klein K3JTE, Chuck Dorian W3JPT, Jan King W3GEY, and Bill Tynan W3KMV, who were just reelected to two year terms of office, and Tom Clark WA3LND, Bill Dunkerly, Jr. WA2INB and Larry Kayser VE3QB, who are in the middle of their terms of office. Bob Carpenter W3OTC was later appointed Secretary, Gary Tater W3HUC, Assistant Secretary, and Roy Rosner WB4UOX, Treasurer. The meeting was attended by about seventy persons. Reports were given on the progress of the next radio amateur spacecraft – the Phase III high orbit project – and on the AMSAT-OSCAR 6 and 7 command and control activities, including the changeover to microprocessor control at the ground command stations.

G3ZCZ displays the new OSCAR award certificate at the AMSAT General Meeting. Photo by W4ART.

Certificates for the new "OSCAR" Award are available and were first shown at the meeting. Full details of the requirements for the award and of the meeting are published in the December 1975 issue of the *AMSAT Newsletter*.

AMSAT-OSCAR 6 celebrated its third birthday on October 15th and AMSAT-OSCAR 7 its first birthday on November 15th. QSL cards are still available from AMSAT for reception reports of the special relay transmissions from the satellites commemorating these anniversaries. The Jet Propulsion Laboratories (Radio Club) at Pasadena, California held an OSCAR month from October 15th to November 15th, with special exhibits depicting the two spacecraft.

A distance record for amateur satellite relay communications has been claimed by G3IOR and W6CG, for a QSO made over a ground distance of nearly 6000 miles. As this path is well out of direct line of sight range, the contact was made using meteor scatter techniques on successive evening orbits. The QSO took two weeks to complete.

The FCC has authorized radio amateurs in the USA equipped for RTTY to transmit ASCII coded signals through the AMSAT-OSCAR spacecraft for experimental purposes. AMSAT is interested in receiving proposals for and carrying out experiments in transmitting computer data via satellite.

New orbit books for 1976 listing all AMSAT-OSCAR 6 and 7 orbits are available from Skip Reyman W6PAJ, PO Box 374, San Dimas, CA 91773 for $3.00 (or 20 IRCs) postpaid.

W2GN has completed tests operating mobile in motion using SSB, via AMSAT-OSCAR 7 Mode B – with fantastic results. His signals were fully audible over most of the East Coast of the USA during the 15 minutes or so that the spacecraft was within his visibility range. These experiments have demonstrated the superior downlink capability of Mode B. If you would like to listen to really good downlink signals for a change, try listening to AMSAT-OSCAR 7 Mode B.

Support The AMSAT Team That Brought Us OSCAR 6 and 7!

Since November 1974, amateur radio has had not one, but *two* long-life OSCAR satellites available for use by the international Amateur Radio community:

- AMSAT-OSCAR 6. Launched October 15, 1972 by NASA piggyback (with NOAA-2, which has long since expired), OSCAR 6 continues to function, having tripled its original one-year lifetime goal.
- AMSAT-OSCAR 7. Launched November 15, 1974 by NASA piggyback with NOAA-4, OSCAR 7 exceeds the capability of the first six OSCARS *combined*.

AMSAT is now developing Phase III spacecraft, intended for much higher orbits. AMSAT Phase III promises to be a considerable step forward beyond OSCAR satellites launched to date, making possible reliable communications over transcontinental distances for hours at a time.

LETTERS

from page 11

meetings are, upcoming hamfests, or whatever you can dream up. You will be wise to keep the number of words at a minimum because the slide has a tendency to look confused with heavy wordage. It also must be pointed out that 15 seconds may be too short for some trifocal wearers to wade through a girthy text.

If your local CATV system has an MSI program, approach the manager and ask him if he has room on his slide projector. He will be more inclined to accept your request if you make the slide yourself. Just have some arty member make an announcement on a 10 inch or so square card and then take a slide picture of it (in color would be a good idea).

Neil Serafin WB2VRZ/2
Syracuse NY

A LOT OF BULL

I'm going to agree with S. Reed and his opinion about *QST* in the October issue. My subscription to *QST* is almost over. I am 13 years old and planning to get a Technician ticket in the near future. By reading an article in *73*, I know a little more than I did yesterday. Steve's letter was most meaningful and I agree with it in every way.

I am going to subscribe to *73* as soon as possible, for *QST* is a waste of time and money for me.

I read *73* whenever I get a chance to. When I do, I turn right to the letters and read the criticism of CB and the CBers. It's unbelievable to find out how many people like CB and the chickens who are on it, but please don't think they're all bad.

I agree that a large percentage of it is just a lot of bull (like channel 10 with the truckers and other stations that don't care if there is someone modulating with another person). If you wish to talk and ask for a break, you won't get one, and, if you do, just try to talk when there are twelve other people talking, plus the mike keyers, garbage mouths and smokey reporters.

If you have a ham ticket, keep it! If you have a CB license — that's alright — don't ruin it or ruin it more. If you're wondering, my father has a CB license, but for me to understand radio I might as well make the best of it with my realistic Navaho TRC/30A. Keep printing those letters!

T. Carlsen
Manlius NY

PINHEAD—PART I

I've been using your 13 wpm code tape for the past few days. It is *definitely* a buster. On my Lafayette player it runs upwards of 16+ wpm, so I use the word thirteen advisedly. I've been a Tech since 1967 and 5 wpm (less numerals and punctuation) used to be like the Myth of Sisyphus. I used to count the dots! I nearly went up the wall with the "IEEIE" code group. Luckily, I'm not an epileptic, or else I'm sure I would have had a grand mal seizure. Gonna take the General exam in a few weeks and if I don't pass the 13 wpm, I'm getting a CB rig and call myself "pinhead". Wish me luck.

Howard J. Margulies WB2FYY
Brooklyn NY

PINHEAD—PART II

After 45 days of bedlam with *73*'s 13 wpm tape, I finally got up the nerve and took the test. Well, I passed, copying roughly 2½ straight minutes before the panic and temporary palsy set in. I guess the realization that this was actually the dreaded "code test" was too much to bear. Now comes the real test of endurance: waiting for my ticket to arrive.

Howard J. Margulies WB2FYY
Brooklyn NY

PROS AND CONS

This is a report on my progress with the *73* code tape I purchased from you. It was the 13 wpm plus tape.

The tape sure did help me over the hump. I was up to about 10 or 11 wpm and could not seem to get beyond that. Mastering that tape did wonders. I spent a total of six hours and thirty minutes with the tape.

I went down to the FCC office here in K.C., Mo., in July, and passed the General test just fine. I then went back in August and passed the Advanced test. I got my General ticket in September and am now waiting for my Advanced ticket.

I think your magazine is the best and those editorials are something else. That is the first thing I read and the next are the letters, which are very enlightening as to the thinking of your readers. Sometimes the pros and cons make me wonder which is right and wrong.

Melvin B. Walker WBØOTW
Raytown MO

Pros are right, cons wrong. — Wayne.

COLLECTOR'S ITEMS

Just a little nostalgia and then I'll get to the point. Back in the late 30s I went to work for RCA Communications out at Rocky Point and got my W2 call — it was W2NSQ. So what you say? Well, wid ur W2NSD, we're both in a pretty close bracket and I have always been able to identify with you for that and a few other reasons. Almost 20 years ago you began publishing your *RTTY Bulletin* — gee, come to think of it, that was *24* years ago! Well, anyway, your Radio Teletype *Bulletin* grew and got a lot of us really turned on, AND provided needed information and techniques. Then came the RTTY column started in 1955 (I believe) in *CQ* when you were running that one. And *then* you had the perseverance, drive, etc., to bring out the *RTTY Handbook*. I have a FIRST EDITION (that was in 1957, if my memory serves me). Anyway, this was just what it took to provide a source of information, a place to go, to get the dope on this RTTY thing. I've been into it ever since!

Well, now what I see coming up is this computer deal! Wayne, this is great! You are coming out with this *BYTE* bit — what a wonderful thing! Comes now a place to find info and knowhow and a chance to really get into this digital scene. So much of it is kicking around but how can a guy get started? Now comes *BYTE* and here is

NO STRINGS

My writing efforts have always been slanted to aid those with limited hobby budgets, by describing more economical methods. Continuing in that vein, in the face of ever-escalating prices, I wish to share an idea which gives more dollars for buying amateur goodies.

For a few years I have enjoyed a free bank checking account which pays 5 percent interest. Personalized checks, air mail stamped envelopes and FDIC insurance are a part of the package. No strings.

Other banks in Massachusetts and New Hampshire offer similar service, but my satisfying experience has been with Home Savings Bank, 69 Tremont Street, Boston MA 02108.

Gene Brizendine W4ATE
Huntsville AL

the answer. Wayne, I'm all for you on this. This is the first step – with *BYTE* going you'll get enough together pretty quick to be able to come out with a computer/digital techniques handbook, and, if I know you, it won't be long coming. So – here is my check for ten bucks to get in on the charter subscription to *BYTE* and I sure HOPE you have a #1 September issue to send along to me – these will be collector's items!

C. P. Cook W5YOU
Houston TX

SETBACK

Amateur radio operators in Tulsa, Oklahoma received a setback on September 18, 1975. The "Tulsa Metropolitan Area Planning Commission" Adjustment Board ruled that amateur operators *do* have the right to have a radio tower and antenna at their residence. However, they ruled, although antennae height was unlimited as far as they were concerned, the tower *is* a structure and as a structure was limited to a 26 ft. maximum height. This ruling is being appealed, of course. The Board indicated that the city ordinance was unclear and needed to be clarified or rewritten. This ruling was made in the case of a group of local residents vs. Jim Picket K5LAD. The Tulsa Repeater Organization, in cooperation with the Tulsa Area Radio Club and the Broken Arrow Radio Club, are drawing up an ordinance proposal to present to the TMAPC to use as a guide for adopting a new ordinance.

Anyone wishing to contribute specific wording or ideas for the ordinance or the K5LAD legal defense fund may do so by sending to Box 1422, Tulsa OK 74101.

Jerry Broderick WB5NXB

ALMOST READY

I just wanted to drop a note to you guys letting you know that I am really impressed with one of your advertisers, S. D. Sales Co. Despite today's runaway inflation, an introduction to tomorrow's world of digital electronics is available today with S. D. Sales' Digital Clock Kit on yesterday's experimenter's budget. This is really a relief to get into a new area of electronics and build a device for just a little more than a sawbuck.

By the way, I would like to thank Paul S. Vydareny WB2VUK, Jim Volstad DA1JV and Ken Mahoney K6OPG for the letters of encouragement and assistance in response to my letter published in your May issue of *73*. It will not be long now before I am ready to take my ham exam.

APO NY 09077

INTEREST-AROUSING

Enclosed are the orders for certain items and for reader service. I am a teacher of physics, chemistry, and physical science. I hope to start an amateur radio club in the high school soon and possibly affiliate with one of the MARS systems. There is some possibility of starting an electronics class in the future, as there is none now here in the Nuernberg (Germany) American High School for U.S. military dependents.

The high school has a computer and terminal for one class in computer math and one in business computer work. I am subscribing to *BYTE* to learn more about computers, particularly at the hobby level, which should be interest-arousing in high school students.

In the past I have sponsored Electronics/Amateur Radio/MARS (Air Force) in Okinawa and in two different bases in Japan with good response. I hope to create interest here. Any other publications or suggestions along both the radio and the computer lines as applied to high school level students will be appreciated.

I have applied for a German callsign through the U.S. Army, as we are requested to do, via the German Post Office (who issues the calls), but it has not arrived as yet.

J. Worth Gurley W7GH
Nuernberg American High School
APO NY 09696

HAM HAWKS

The article in *73* (October, 1975), by John Murray W1BNN, was certainly nostalgic of early flying and the old Five Meter band. One important and interesting fact omitted by the author, however, was that the famous Frank Hawks was a ham! Indeed. And a good CW man he was. I recall working him several times on 40 meters in 1935. His call was W1IJI.

Ben F. Holloman W5CP

FIRST RATE

Thank you for putting out a first rate magazine.

Kenneth D. Grimm K4JGI
Sweet Briar VA

LO AND BEHOLD

The FCC exam had me scared. I bought one of those question and answer books, failed the exam, lost 9 bucks, made my wife mad and lots of other bad things.

Lo and behold, *73* says, "purchase one of our books and breeze through the tough FCC exams." Well, I did!

Yesterday (9/3/75) I passed the Advanced amateur exam. Whether or not I breezed through, I don't know, but you have the best book out, and take it from one who knows.

If you really want a simple explanation to a complex question, purchase a study guide from *73* – and then face the examiner with confidence.

Ancel W. Norris WB4AUB
Birmingham AL

WHERE ARE THEY?

On page 8 of your magazine for October 1975, there's a well written article by a 16 year old. These are my views also. Formerly a general contractor, my knowledge of electronics can be put in a thimble. Why not take heed of this youngster's letter and start devoting articles to us non-eggheads in electronics? We just want to be ham operators.

I'm a subscriber to both *73* and *QST*, but find little for persons like myself to really read and enjoy.

Just where are all these hams who want to help amateur radio to continue, and help persons such as myself and others to become hams???

Your tapes are helpful.

Basil W. Polenchak, Sr.
Box 81 SV Sta.
Andover MA 01810

ONE IN THE BAG

I have decided to gamble $16 on the presupposition that your magazine will continue to hold my interest for an additional three years beyond my current expiration date. As best my records show, we are talking about *extending* my subscription to the March, 1981 issue. I'm assuming that you will accept this inflation-fighting effort, understanding that a subscriber in the bag is worth three in the hands of the competition. Therefore, please find enclosed my check for sixteen dollars.

The basic TTL primer article by WB5IRY (Aug. 75) was excellent and much needed to get me started in IC *understanding and experimentation.*

Keep up the good work.

Joseph R. Nelis, Jr. K3JZD
Trafford PA

ON THE GROUND FLOOR

I enjoy *73* very much. I have been getting it on newsstands, but when I read subscriptions were going up soon I decided to take advantage of the lower subscription rate while I still had the opportunity. So, herewith is my check for $8.00, for twelve issues of *73*. Thank you.

I would like to get in on the ground floor with a charter subscription to *BYTE* but I will have to wait until later in the month. But you will be

CONTESTS

CONTESTS & AWARDS from Jock ZL2GX

ASSISTANT CONTEST MANAGER - PETER KENNY ZL2QK

Jock White ZL2GX, one of ZL's best known hams, will be leaving New Zealand by air 12 December 1975 with his wife for a long awaited holiday in the United States. Jock is well known on the bands and through *Break-In*, the NZART Official Journal published monthly. For 27 years he has been Contest and Awards Manager, issuing certificates and awards and writing the column, "The Contest Manager Speaks" (in more recent years, "Contests & Awards from Jock ZL2GX, with Assistant Contest Manager Peter Kenny ZL2QK"). This involves lots of work — sometimes running into five pages of copy faithfully turned out in a busy life (he is the Headmaster of a large school in Gisborne). Jock has fostered ham radio with the same tremendous energy he throws into all his work, and his and Beattie's hospitality to visiting hams has been fabulous.

Visiting ham friends in the US will be an enjoyable experience for them both. If you meet him, he'll hit you like a whirlwind, strike you with his humanity, and leave you the better for knowing him. He's a big man in every way.

NATIONAL CAPITAL DX ASSOC. USA BICENTENNIAL AWARD

The award will be issued to any licensed radio amateur in the world for contacting ten different members of the NCDXA using the special bicentennial callsigns during the 1976 Bicentennial year. Any band or any mode from 1.8 to 29.7 MHz may be used but there will be no endorsements for band or mode or for more than 10 QSOs. The fee for the award is 50¢ for all US stations, but free for all DX. No QSLs are required; send log information only to: NCDXA Awards Manager, Raymond E. Spence W4QAW, 10013 Coach Road, Vienna VA 22180 USA.

NCDXA MEMBERS:
AC3AFM, AC3AFQ, AC3AZD, AC3BQV, AC3BWZ, AD3CHP, AC3COR, AC3CRE, AC3DBT, AC3EZT, AA3HRV, AC3KA, AA3KSQ, AA3MBQ, AA3NHG, AA3NGS, AC3NL, AC3QW, AC3SW, AD3EH, AC3ZNH, AD3ZAW, AC3ZSR, AD4CFB, AD4CTY, AD4DXO, AD4EBY, AD4EKJ, AD4GKD, AC4IDG, AC4KFC, AD4KQB, AD4OMR, AC4QAW, AC4UMF, AC4WSF, AD4WVT, AC4WWG, AC4DPS, AA4HPF, AB2EXK, AC2GHK, AC9SZR, AC3RX.

DELAWARE QSO PARTY

Starts: 0001 GMT Saturday, December 6
Ends: 2400 GMT Sunday, December 7

This year's Delaware QSO Party is sponsored by the Delaware Amateur Radio Club W3SL, and is open to all amateurs. Stations may be worked once per band, per mode, for point credit.

EXCHANGE:
Delaware stations give QSO number, RS(T), and county. All others give report and ARRL section, province, or country.

FREQUENCIES:
CW: 3560, 7060, 14060, 21060, 28160
Phone: 3975, 7275, 14325, 21425, 28650
VHF: 50.110, 146.52
Novices: 3710, 7120, 21120, 28160
Phone on even hours, CW on odd hours.

SCORING:
Delaware stations score 1 point per QSO times number of sections, provinces, or countries. Outside Delaware, score 5 points per Delaware QSO times 1 for one county worked, 3 for two counties worked, or 5 for all three counties worked (New Castle, Kent, Sussex).

AWARDS:
Awards will be given out, as well as certificates for working all three Delaware counties.

LOGS:
Mailing deadline is January 15, 1976; include an SASE for results or W-DEL Award. Logs should be sent to John Low K3YHR, 11 Scottfield Dr., Newark DE 19713.

MILWAUKEE AREA CHAPTER OF THE 10-X NET QSO PARTY

Starts: 0001 GMT Saturday, December 6
Ends: 2400 GMT Sunday, December 14

Stations may be worked on all bands, once on each band. All contacts must be made using voice transmission.

EXCHANGE:
IDs, QSO number, Milwaukee Chapter number, 10-X number, and state.

SCORING:
Score one point for each initial contact, 1 extra point if on 10 meters, 1 extra point if station is a 10-X member, or 1 extra point if station is in Wisconsin. Score 2 points if person contacting is a Milwaukee Chapter member. Thus, one QSO could score 6 points total.

AWARDS:
Plaques to the first and second place winners. Certificates for the next two highest scorers in each state (3rd and 4th).

LOGS:
Logs must list exchange information plus date, time and band. All logs must be received by WA9TSG no later than January 15, 1976. All logs will remain the property of the Milwaukee Area Chap. of the 10-X net. Send logs to: Joseph F. Williams WA9TSG, 114 East Brown Street, Milwaukee WI 53212.

TELEPHONE PIONEER QSO PARTY

Starts: 1900 GMT Saturday, December 6
Ends: 0500 GMT Sunday, December 7

The Stanley S. Holmes Chapter Ham Pioneers invite all Telephone Pioneer ham radio operators to participate in contacting as many individual members in as many different chapters as possible. All bands may be used and the same station may be worked on more than one band. General call is "CQ TELEPHONE PIONEERS" or "CQ TP" on CW.

EXCHANGE:
RS(T), number, chapter name and number.

SCORING:
One point for each completed exchange and one point for each different chapter contacted.

SUGGESTED FREQUENCIES (± 20 kHz):
Phone: 3965, 7206, 14295, 21365,

Robert Baker WA1SCX, 34 White Pine Drive, Littleton MA 01460

28676, 50.1 to 50.25 & 144.275 to 145.5
CW: 3565, 7065, 14065, 21065
REPORTING:
Send log extract showing date, time, station worked, chapter name and number, contact number — postmarked not later than January 10, 1976 — and send to: Gene Przebieglec, Stanley S. Holmes Chapter No. 55, Telephone Pioneers of America, 100 Central Avenue, Kearny NJ 07032.

TOPS CW CONTEST
Starts: 1800 GMT Saturday, December 6
Ends: 1800 GMT Sunday, December 7

All contacts must be made between 3.5 and 3.6 MHz. On CW, leave the low end of the band for DX. General call is CQ QMF.
SCORING:
Contacts with own country count one point — each call area in W/K, UA, etc.; VE/VO and VK counts as a separate country. Contacts with stations in same continent count two points. Contacts with stations in other continents count five points. Total score is total points times number of prefixes worked (prefixes same as for WPX).
LOGS:
State if single or multi-operator and mail logs not later than January 31, 1976 to: Peter Lumb G3IRM, Tops CW Club Contest Manager, 14 Linton Gardens, Bury Saint Edmunds, Suffolk IP33 2DZ, England.

ARRL 10 METER CONTEST
Starts: 1200 GMT Saturday, December 13
Ends: 2359 GMT Sunday, December 14

The contest is open to all amateurs worldwide. All QSOs must take place on 10 meters and OSCAR QSOs are valid. Each station can be worked on phone-to-phone and CW-to-CW, and anyone can work anyone. All CW contacts must be made between 28.0 and 28.5 MHz, unless working through OSCAR. When operating on 10 meters, please avoid the OSCAR downlink frequencies.
CLASSES:
Entries will be classified as either single or multiple operator stations. Multiple transmitter stations are not allowed.
EXCHANGE:
All W/VE stations will send RS(T) and state or province. Others will send RS(T) and consecutive serial number starting with 001. Stations that are not land based will send RS(T) and ITU Region (1,2 or 3). The District of Columbia is counted as part of Maryland.
SCORING:
Each completed QSO counts 2 points, or 4 points if with a W or K novice. The multiplier is the sum of the total number of states, Canadian call areas (max. 9), ARRL Countries (not US or Canada), and ITU regions from non-land based stations. Final score is the sum of the QSO points times the total multiplier.
AWARDS:
A certificate will be awarded to the highest scoring single operator station in each section, Canadian call area, and foreign country. Region awards for non-land based stations, and awards for multi-operator and Novice stations will be issued if warranted.
FORMS:
It is suggested that contest forms be obtained before the contest from ARRL, 225 Main St., Newington CT 06111; include an SASE. Check sheets are not required but a penalty of 3 additional contacts will be made for each duplicate contact.
These rules were taken from last year's contest; for complete rules see the November issue of QST.

HA5 — WW CONTEST
Starts: 0000 GMT Sunday, December 28
Ends: 2400 GMT Sunday, December 28

The full 24 hours may be used on all bands/modes. Classes (sections) include: single op, multi-op, and SWL. General call is WW TEST DE . . .
EXCHANGE:
RS(T) and ITU zone number.
SCORING:
Contacts within own continent count 1 point, between continents 3, with HA/HG5 stations 4, and 5 points with the special HA5 prefix. Multiplier is the number of different ITU zones.
AWARDS:
Certificates to the top scoring stations in each category, in each country.
LOGS:
Send usual log data, summary sheet, and signed declaration to: BRAL Contest Committee, PO Box 214, Budapest 134, HUNGARY.

NOSTALGIA RADIO EXCHANGE
Starts: 1900Z Saturday, January 3
Ends: 0500Z Sunday, January 4
Starts: 1900Z Sunday, January 4
Ends: 0500Z Monday, January 5

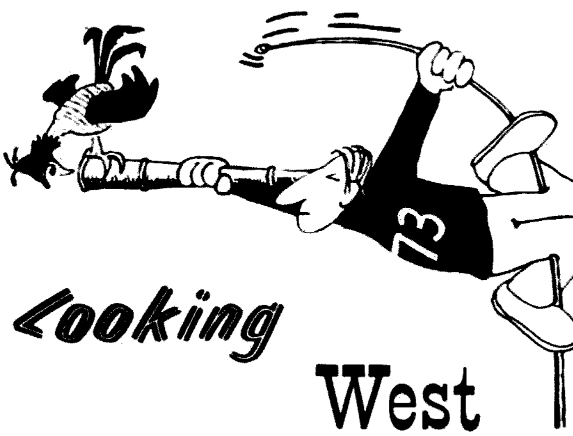
Nostalgia Radio Exchange is sponsored by the Southeast Amateur Radio Club, Cleveland, Ohio, and is open to all. The object is to have civilized fun in working as many interesting persons and old rigs with your interesting old rig (a Nostalgia Rig is any gear built since 1945 but at least ten years old — an advantage, but not required in the Exchange).
EXCHANGE:
Your name, RST, state/foreign country, transmitter type (home brew: Use P.A. tube, i.e., "807"). The same station may be worked on each mode on each band. No AM phone below 28 MHz. CW call "CQ NX," phone call "CQ Exchange."
FREQUENCIES:
1810 and CW up 70 kHz from low band edges; phone 3910, 7280, 14280, 21380, 28580; Novice 3720, 7120, 21120, 28120.
SCORING:
To score, add the numbers of different transmitters, states and countries for each band. Multiply by total number of QSOs. Multiply that total by Nostalgia Multiplier: total years old of your transmitter and receiver (if transceiver, multiply years old by 2). Different transmitter and receiver combinations may be used by one station: Figure scores separately for each and combine for total score.
AWARDS:
Achievement Certificates for persons scoring 150,000 or more, plus Special Citations for unusual circumstances as determined by the committee (like working Antarctica with an AT-1). Send logs, comments, anecdotes, and legal sized SASE to Southeast Amateur Radio Club, c/o W8KAJ, 2386 Queenston Road, Cleveland Heights OH 44118.

Don't forget to send early for your contest logs and summary sheets for the ARRL VHF Sweepstakes (Jan 3 - 4) and the ARRL DX Competition (Feb 7-8 and 21-22). Include a large SASE with sufficient postage. Send requests to: ARRL, 225 Main Street, Newington CT 06111.

CALENDAR

Dec 5 - 7	ARRL 160 Meter Contest*
Dec 6 - 7	Delaware QSO Party
Dec 6 - 7	Telephone Pioneer QSO Party
Dec 6 - 7	TOPS CW Contest
Dec 6 - 14	Milwaukee Area Chap. 10-X Net QSO Party
Dec 7	TU2 Competition
Dec 13 - 14	ARRL 10 Meter Contest
Dec 28	HA5-WW Contest
Dec 31	Straight Key Night
Jan 3 - 4	ARRL VHF Sweepstakes
Jan 10 - 11	ARRL CD Party — CW
Jan 17 - 18	ARRL CD Party — Phone
Jan 24 - 25	Simulated Emergency Test
Feb 7 - 8	ARRL DX Competition — Phone
Feb 21 - 22	ARRL DX Competition — CW
Apr 3 - 4	Florida QSO Party
May 1 - 2	Helvetia 22 Contest (H22)

* = described in last issue



Looking West

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

In case you had not noticed, 1975 has fast drawn to an end, and to say that it has been a most interesting year for amateur radio would be an understatement. Nationally, the controversy brought about by Docket 20282 and the profound long reaching effect that the final report and order would have on the future of the amateur service has stirred the thinking of just about all of us. It has made many of us realize that the key to our survival and growth is recognition and total acceptance by the general public. It is still my sincere feeling that you cannot legislate people into the amateur radio community; through the proper education, though, we can instill the necessary desire and interest for them to take their own initiative to join our ranks – because becoming a "ham" holds the kind of challenge they find necessary in their lives. In '75 we saw the dawning of this new era first with the Hawaii Ham Forum, a radio program produced by members of the Hawaiian Amateur Community and directed specifically toward the non-amateur listener. As the realization that it would inevitably be the general public that would decide the destiny of amateur radio took hold, and that the best way to reach the public was through the broadcast media, the ARRL leadership here in Southern California was quick to act by appointing Lenore Kingston Jensen W6NAZ (a person whose credentials for the job would take a column in itself) to the post of liaison with the broadcast media in Southern California. Lenore is the type of person one feels honored to know is a member of our amateur radio community.

We have come a long way in '75, and challenges still await us in the coming year. Such a challenge is the future of a statewide FM coordinating body known as the California Amateur Relay Council. If you are a regular reader of LW, then you are aware of the fact that CARC is in the process of total metamorphosis. Racked with dissension from within the organization itself, charges that the organization was not responsive to the needs of northern repeater interests, and the fact that a split was developing between repeater and non-repeater interests, the organization took on the job of revamping its structure in order to try in some way to placate all concerned. A blue-ribbon committee was formed, given time to study all related matters, and, as reported in an earlier column, voted in October as to which direction to take. We will have a report on their decision next month.

In the interim, however, another organization is in the process of getting itself together in Northern California. As the Southern California Repeater Association was formed a few years ago when local leaders here came to the realization that the existing statewide body was not at that time serving their needs and interests, so it appears that similar interests in the north are following in the same direction with the announcement that the Northern Amateur Relay Council (or NARC for short) had been the outcome of a meeting held September 20th in Sacramento. Hosted by the Mt. Vaca Radio Club, this meeting was well attended by some 200 delegates of both repeater and remote base interest. It was agreed by the vast majority that some form of regional "home rule" organization could best be responsive to the needs of area FMers, and a group of eight area amateurs plus one alternate was chosen to represent the organization and help get it started.

Well, the year end "box scores" are in regarding repeater operation in the Southland, and here, directly from the latest SCRA Newsletter, is where we stand. Two meters is bulging at the seams with 61 systems currently sanctioned to the repeater sub-band, plus (unfortunately) 5 systems whose owners do not feel that coordination is necessary. Of the 61 coordinated systems, only 15 are listed as private, with the rest being considered "open." Six of these systems are listed as having autopatch facilities, but it is best to check with a given system (as to whether this facility is open to all or limited to specific individuals) before going "gung-ho" on such a repeater. The channel pair of 146.10-.70 is reserved for RTTY repeater operations.

Now, here is the best part: Nine of the above are inverted or "California Plan" split-split systems, and no one to date has come running to the SCRA Technical committee yelling foul! It looks as though this method of using the 15 kHz tertiary channels is meeting with good success, much to the credit of Burt K6OQK and Bob WB6JPI, who thought it up, and to the SCRA, for accepting this radical departure from tradition and having the wisdom to give something new a chance to be experimented with. Of late, reports have been reaching me that other areas of the country have been considering going this route rather than following the Texas Plan (that does not invert the tertiaries). As one who had the sometimes dubious honor of being among the first to try a split-split repeater according to the Texas Plan (doing so at a time before the Texas Plan was known as the Texas Plan), and now witnessing firsthand the results of the Southern California Inverted Plan, I only wish that I had been the one to dream this one up myself. If you reside in a megalopolis such as ours, with all your standard 30 kHz channels allocated and in use, might I suggest that you give serious consideration to what has been accomplished here? The inverting of the split-splits is a reality and, moreover, it is a success. Simply said, it works. A letter to the SCRA at PO Box 2606, Culver City CA 90230 (and marked to the attention of Tech Committee Vice Chairman Bob Thornberg WB6JPI) will probably bring you as much information on this topic as is available to date.

Now, can you believe 30 systems already sanctioned to 220 MHz with the number still increasing? Now remember that a sanction does not mean a machine is in daily operation, but it does stipulate that the amateur receiving said sanction has but 90 days to get his system operational (and within SCRA guidelines). All these systems must be on the air by January, or the channel assignments will be up for grabs. My personal opinion is that most if not all will make the deadline – thereby making L.A. and vicinity a veritable beehive of 220 activity.

My Clegg FM-21 is crystalled for five of the listed systems, plus 223.5 simplex. Of these five, two are in regular operation, with WR6AER accounting for the bulk of the activity. While two out of five might not seem like a lot, in terms of percentages it comes to 40% of my crystals being useful. A directional antenna on 220 would do wonders for the other 60% (they're all for operational systems) as well as my simplex range. As for the latter, there is a darn nice bunch of people operating 223.5 here in the San Fernando Valley, and most of the time when the 220 radio is on, it monitors that frequency. If I am home, a short call on that channel will usually get a response. If I am not home, well, the phone number is 786-6829 and Sharon is adept at taking messages . . . hi.

So there is the total: 91 sanctioned repeaters, one special events sanction and five unsanctioned or renegade repeaters – all within the "jurisdictional boundaries" of the SCRA (and currently nine more applications pending for coordination to two meters). I find it all but mind-boggling how FM has grown in the three years since we arrived here. Grown? No, skyrocketed!

There are still no purely open 450 systems in the area yet, but rumors persist that this situation will soon be changing. Activity on that band is such that a non-area ham might have trouble believing that so much activity could be packed so tightly into one band. I didn't, until I was given a firsthand demonstration about a year ago. The technological level of some of the 450 remotes and repeaters is

probably the most sophisticated in the world — a credit to the inventiveness of the amateur radio community.

Alas, this leaves us with but one veritable wasteland, six meters. While there is a fine open repeater system, WA6UJS, located atop Mt. Wilson, with coverage that rivals anything else in the area other than WR6ABE (2 meters, also atop Mt. Wilson), it is rare that I hear any activity on that system. I understand that there is another system down San Diego way, but I cannot hear it from my location. Going to the low end, aside from a few AM nets and a minute amount of SSB activity, there is little to speak of. Even when the band was "open" during "E" and "F2" skip this summer, there was not much activity to be noted. Oh, the "Big Gun" DXers were there, but that was it. No new blood — that was the six meter scene about five years ago. Even with the availability of multi-channel amateur FM transceivers, six meters seems to be going in the opposite direction from 144, 220 and 450. Days can go by without hearing anything but the few AM nets. A sad commentary on a great band!

I hate to see 6 just go down the tubes. Oh, I hear the same old reason given time after time: TVI. But let me pose a question. Aside from the TVI potential of the repeater transmitter itself, and this can be located in an area isolated from TV viewers, how much TVI can you give from your car? Do you really think someone is going to run out of his home to complain as you sit waiting for the traffic light to change? Sound silly? So is the old TVI excuse for avoiding six! It might have held some merit back in the pre-FM repeater days, but a lot has changed over the past few years.

Now there is rumbling coming from Washington that the television industry wants the band back to create a channel 1 TV station for educational purposes. Do we sit idly by and wait for the day when the FCC says, "Pack up your Gonsets, guys, it's not your band any longer" or do we start now to populate this band in numbers that will avert its eventual loss? Don't think it can't happen; remember the Class E CB thing of a few months ago? A good motto for the next 12 months might be "Save 6 in '76" or something along those lines. It's a darn good band with tremendous growth potential. Let's not lose it.

The mention of television brings us to the question of the media and our relationship with it. We have two things to report this month, one older news and bad, the other new and very good. First to the former. If you have not already heard, the production team of Spelling-Goldberg (the company that brings you the police action drama show *SWAT*) is in the process of readying an episode of that program that puts the amateur radio community into a rather unfavorable light. It seems that the "bad guy" in the particular episode is a "ham" who uses his radios to befuddle the police. It seems that Mr. Spelling is not willing to make very many concessions if any as to dialogue (something that as a producer he has the artistic privilege to handle in any way he sees fit). Therefore, until the episode airs on ABC, no one is exactly sure of what will be contained therein, and though I hate to seem pessimistic, I doubt if a letter writing campaign will do much to keep it off the air. This may be one where we lose the battle, and can only hope for minor consequences as a result. If the content of the show is such as to be deemed slanderous to the amateur radio community, then legal action can only be taken after the program airs. In the interim, we must take a wait-and-see attitude; we have no other option. The only thing that bothers me is that with the multitude of amateurs within all aspects of the media, and a good possibility of there being one or two employed by this production company, why didn't they put out feelers for an episode technical advisor from within the Los Angeles amateur community? Why is it so rare that the media ever consults us when they are going to picture us? These are the questions and barriers that we must work to overcome, and this is what good public relations is all about.

Now that we have expounded on the dark side, let's get to something good. Educating the younger members of our society, the children, is one way to insure our future growth. If we can instill in them a feeling that amateur radio is a challenge of the future, then half of our problem is solved. Reaching these little people through children's programming is one way, since the reason that children watch TV is that they enjoy it. One of the top rated children's programs is the Saturday morning show *Shazam/Isis*, a two part program actually with two separate programs in a one hour slot. (Consult your local TV listings.) I am pleased to be able to report that Art Nadel W6TZY has written a script for *Isis* titled "No Trumpets, No Drums" that is now in production and will be aired in the near future. It will, I am told, depict amateur radio to our younger generation in a proper light — and one that they will be able to understand. Since no air date is available yet, watch your local TV listings for the title. If it's as good as Lenore says, and I never doubt her word, it may be the first step toward a new generation of amateur operators.

And with this, we begin another year. At this point a personal note to you all: Thank you for your ongoing Xmas gift — the letters of support and encouragement that arrive throughout the year. It's these letters that let me know what you want to hear about, and I consider you all an important part of this ongoing monthly endeavor. It is you who make Looking West possible; you are as much a part of it as I am.

To each of you individually, Sharon and I send our warmest wishes for a most joyous of holiday seasons and hope that all the dreams you have for the future come true in '76.

LETTERS

from page 15

getting my money for that interesting journal, also.

I enjoy every feature of *73*, even your editorials. Some of them I agree with and some not. But mostly for. You have a lot of common sense in your arguments and I like that very much. You can quote me.

Francis K. Cassels W1GVA/1
Calais ME

CAN YOU BLAME US?

In the September issue of *73*, Mr. Glenn Knight commented on my piece in July's "Be My Guest." Mr. Knight puts forth a strong argument that many people are interested in amateur radio but are unable to find a willing ham to show them the right way. As much as I hate to admit it, Mr. Knight is correct. Too many hams don't really care if the ranks are growing smaller. Many hams don't care much about their hobby in general anymore, and that is a shame.

I wrote my article on public relations for those people who are willing to go out and grab the chance to interest people in amateur radio. I wrote the article from my own experience and I was lucky enough to have several hams around that would bend over backwards to help. But I do agree with Mr. Knight that there are far too many hams around that are prejudiced and turned off to those who aren't yet well versed in the ways of hamdom.

Hams in general are prejudiced. They are prejudiced against lower classed hams, higher classed hams, hams that work a different mode, hams that have different interests. Almost all hams are against CB and I guess I'm no exception. We see them getting something for nothing and then using it wrong — while we work for what we have. How can you blame us?

Nonetheless, CBers are our biggest reservoir of prospective amateurs, and we should be showing them the way. Mr. Knight says that CBers talk to anyone and that fact only will turn people the CB way. We, as amateurs, who enjoy our hobby, have to get out and be friendly and quit being so damned snobbish. Such a hard thing to do for some, but it might be the key to keeping our hobby around.

Some hams don't realize why I'm putting on such a push for enrollment. It is the simple fact that the ITU conference, to be held in 1979, will say yes or no to the existence of amateur radio in the US. The FCC is in fact trying to help through Docket 20282, but I do believe they're not quite on course with their suggestions. There must be enough amateurs to show a need for existence. As usual, nobody looks at what we are doing but instead how many of us there are doing it.

To save amateur radio we must increase our numbers. If all we have to do to do that is be friendly and give others our knowledge, let's do it!

Mark D. Poss WB8URH
1365 Brookside Dr.
Fostoria OH 44830

TRIPPING

I am planning to make a trip around the world after I graduate from college in December. I would like to know if there are any amateurs in Japan, Israel, Scandinavia, Western Europe, the British Isles, or French Canada who read *73* and who would like a visitor from the United States. I'm 22 years old, a linguistics major who speaks several languages, and am very interested in making contact with amateurs in the countries mentioned that I plan to visit. All replies will be appreciated, and answered.

Jon Forrest WB6EDM
21414 Oe La Osa St.
Woodland Hills CA 91364

PROGRAM OFFER

With regard to "Say, OM, Are You A Computer?" (October, 1975, p. 109), the program's writer makes the following offer:

He will send a punched paper tape copy or a listing of the program to anyone who writes him to ask for it, and includes a dollar to cover his costs ($2.00 for both). His address is:

Robert Snider, Jr.
57 Hawxhurst Road
Huntington NY 11743

Frank Kelly W2IAT
Huntington NY

BAMBOO DX

I built the "El Cheapo Superbeam" of WA6NLQ's, which was in the June 1975 issue, and it is working very well — I got my first DX across the ocean on it first day of use.

I had trouble finding 13 foot bamboo poles, but 9 foot bamboo and 2 x 2 lumber worked fine.

Charles McBride VE3GYT
Grimsby Ont

PUSHING HAM

I just wanted to say "thank you." Reason? I've been involved with CB (please read further) for about 11 years. After reading *73 Magazine* for about 7 months now, the philosophy of international communication finally got through my thick head. I own a small CB business and am starting to lose a little business — but gaining in cleaning the air waves. By this I mean I've started on my way to becoming a Novice. Thanks again! I push ham every chance I get now!

George Weed
Vineland NJ

OL' KEN

IDF has done it again w/his HW-7 article! Ol' Ken's writing is purely delicious! Bet you edit it very little.

Encouraging trend now in NW is more code classes and more requests for info on becoming hams!

Anxiously awaiting my copy of new VHF Antenna Handbook . . .

Clair L. Mackie W7IJY
Everett WA

INVALUABLE

After several years of your magazine and many interesting and informative articles, I decided that it was time to write and let you know that your magazine is read and appreciated. The articles on surplus and antennas have been invaluable guides to operating on a rather meager hobby budget. The FM articles have been interesting and encouraging enough to get this confirmed HF brass pounder to consider putting a rig on Two Meter FM.

Thank you very much for your time and keep up the good work with the magazine.

Robin D. Huckaby WB4GKI
Norcross GA

CAUTION

I am writing in regards to Sig Peterson's letter in the October 1975 issue relating to the HP-45 "timer." You should caution your readers that it is a counter and not a timer. The timing has not been calibrated by HP and therefore runs at an uncalibrated speed. My HP-45, for instance, is six seconds slow over a ten minute period.

J. Bradley Flippin K6HPR
San Diego CA

IF ONE GETS IN. . .

How about running more articles on inside antennas for some of us who live in one story complexes with a small attic and no floor? No outside antennas are allowed. In fact, no wires are visible; everything is underground.

Also, how about some articles on TVI filters for 6 meters? This was a busy band, but today it's practically dead. We're blessed with channel 2. Everyone is going 2m FM and 50 MHz is a graveyard. I understand some Dallas outfit has petitioned the FCC to use 50 MHz for a TV station. If one gets in, that's it. We can't afford to lose any frequencies.

Sherman Goldman K8LUY
Southfield MI

CASH SUPPORT

Enclosed is $26. Please renew my subscription to *73 Magazine* for three years and give me a one year charter subscription to *BYTE*.

I'm parting with all this cash to support your editorial policies of telling it like it is and providing the most ads and articles each month.

I also share your enthusiasm for microprocessors and spent part of this morning ordering parts for my system. I'm basing my system on the MCS6502, an 8 bit NMOS chip just made available by MOS Technology, Inc., Norristown PA — for the bargain price of $25. They plan on introducing a combination 64X8 RAM, 1024X8 ROM, 16 bit I/O chip this fall — also for about $25. Their ROM portion is not field programmable, but will be supplied factory coded with either a teletype input monitor or a keyboard input, CRT display output monitor. The monitor programs will allow you to enter programs from your keyboard on TTY, then execute them. To my knowledge, this is the least expensive way of getting a system up and running. The MCS6502 is comparable to the Intel 8080 and the Motorola M6800.

I have some news of interest for 8080 users. In mid-August, Intel introduced the 8080A, a redesigned 8080 with full TTL drive capability on all outputs for $150. At the same time, they announced a number of new LSI support chips, including:

- 8708 — 1024X8 erasable PROM 450ns;
- 8224 — clock generator/driver;
- 8228 — system controller/bus driver;
- 8214 — interrupt controller;
- 8255 — programmable peripheral interface (24 bits of I/O);
- 8251 — teletype interface chip (5 level or 8 level).

For $250, Intel distributors (Cramer) will sell you a 13 chip set including an 8080A and one each of the above chips. I ordered a set when they were first announced for a company project, but it wasn't scheduled for delivery until mid-October. These new chips allowed me to design a complete system, including 2KX8 PROM, 1KX8 RAM, CPU and I/O, on a single 5.5" x 7" printed circuit board.

I'm also designing a 12KX8 RAM board using 4KX1 dynamic RAMs. These currently go for $23 each, but by the end of next year I expect they'll sell for ½ of that. Refresh requirements can be handled automatically with about 10 ICs with minimal interference with the microprocessor.

Jack Regula WA3YGJ
Conshohocken PA

SUGGESTION

If there is a ham who has a General ticket (or above) and wants to help others, here is a suggestion.

Many Novices and non-hams enjoy listening to the voice bands. If a General ham would give instruction to the Novices and non-hams, it would be great! A General class ticket is very important to me and other Novices, I'm sure.

My wife and I had a nice vacation last month. While driving through some pretty isolated areas of Wyoming, we both found it comforting to check into the Independent County Hunter's Net (14.333 MHz all day). We were in places where it was 50 to 60 miles to the nearest service station and CB was useless in case of emergency. Viva la difference! Apparently the news travels slowly from Washington — people in the mountain states were driving at whatever speed they wanted to.

My thanks to WA5RON, WB0LSI, K4FRX, WB8TFP, K4HXW, K8YFX and others who dropped me a note telling of their nets. They are included in this edition.

Clocks...

by
Larry Kahaner WB2NEL
4259 Bedford Ave.
Brooklyn NY 11229

A clock is a device that emits pulses at designated intervals. The pulses, either logic 0 or 1, can be used to synchronize different parts of a circuit so they function or turn on at the same time . . .

All right already: what's a clock? That's what many readers have asked, and this article not only answers the question but shows how to build one and incorporate it into a complete IC experimenting unit. And to satisfy those who have asked for simple projects to show IC logic "even if they don't do much," we have that, too.

First, a clock is a device that emits pulses at designated intervals. The pulses, either logic 0 or 1, can be used to synchronize different parts of a circuit so they function or turn on at the same time. For instance, we may have five flip flops in one circuit and want them to activate together. By connecting them to the same clock we are assured that they operate simultaneously.

If we have a clock that pulses at one second intervals and it drives a seven segment LED so that numbers are counted, we have a clock, in the everyday sense.

555 IC Chip

The heart of the clock is the 555 IC chip shown in Fig. 1. The internal circuitry is complex. The equivalent circuit made of discrete components takes over twenty transistors, half a dozen resistors and a few diodes. It is a linear device.

It has many uses, but the two most common ones are astable operation, where it continues to emit pulses, and monostable, or "one shot," where it acts as a timer and pulses once at a predetermined time.

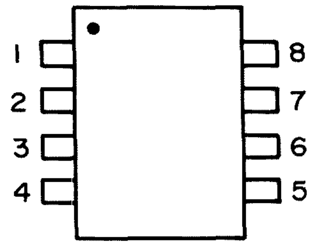

Fig. 1. 555 timer. 1 – ground; 2 – trigger; 3 – output; 4 – reset; 5 – control voltage; 6 – threshold; 7 – discharge; 8 – Vcc.

The circuit for the one shot timer is shown in Fig. 2.

Pin 2 is the trigger and a pulse under 1/3 Vcc will set an internal flip flop. This flip flop releases the short circuit on C_1 imposed via pin 6. This in turn drives the output (pin 3) high. The capacitor now starts to charge (remember τ = RC) and when it reaches 2/3 Vcc the flip flop is reset by a comparator and the output goes low, as the capacitor discharges quickly. 2/3 Vcc is the threshold voltage.

A very good feature is that once triggered, the clock will not retrigger until the elapsed time is up. Then it can be manually reset. However, if we do want to retrigger it during the timing cycle, all we

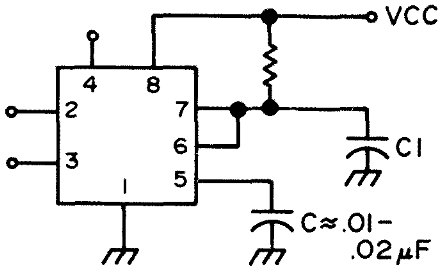

Fig. 2. One shot timer.

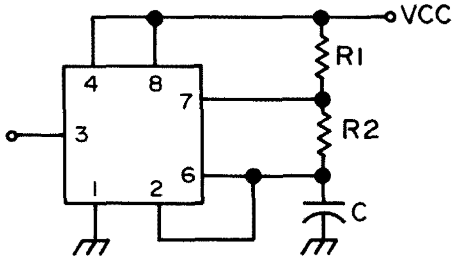

Fig. 3. Astable operation.

Really Simplified!

have to do is pulse both pin 2 and 4 at the same time and the cycle will start again.

To prevent accidental retriggering during a timing cycle, pin 4 should be connected to Vcc to insure that it cannot go low. The equation for timing is approximately $t = RC_1$. R is given in Ohms and C_1 is in farads. With the proper values, timing from many hours to hundredths of a second can be obtained. (For an application see "The Alligator Squelcher," *73*, Sept. 75.)

The astable operation is the mode we have been discussing most of the time. The circuit is shown in Fig. 3.

It is similar to the one shot except that pins 2 and 6 are connected together. That's right; it triggers itself. The capacitor charges to 2/3 Vcc, then discharges. When it discharges to 1/3 Vcc, the clock triggers via pin 2 and another cycle commences. 1/3 Vcc is known as the trigger voltage. The cycle is dependent upon R_1, R_2 and C. The frequency is equal to $1.4/(R_1 + 2R_2)$ C. The graph makes it easy (Fig. 4).

Building the Clock

As you can see from Fig. 3, there is not much to it. After I breadboarded it, I just took the whole thing and mounted it inside the same chassis as the 5 volt power supply. Parts layout is not critical (I always wanted to say that), and since the clock draws so little current, I leave it connected to the supply output all the time.

To obtain variable speeds two choices are available. One is to vary the resistors, the other is to vary the capacitor. Because I had no potentiometers of the correct value, I decided to leave $R_1 + 2R_2$ constant at 10 megohms and use a rotary switch to select a 1, .1, .01 or .001 uF capacitor. This gives speeds of .1, 1, 10 or 100 Hz. For a precision clock, keep adjusting until the proper speed is reached while checking against a known reliable source like an oscilloscope or counter.

If an LED is connected to the output (you may need a dropping resistor of 150 Ohms or so depending upon your LED), and the speed is slow enough, you will see that it stays on longer than it blinks. This is correct. As mentioned before, the output is high during the timing cycle. However, the change is the important thing and that occurs at the proper time according to the RC ratio. The logic state in the "between times" does not really matter.

Continued

No excuses for non-IC experimenting will be valid after this article is digested . . .

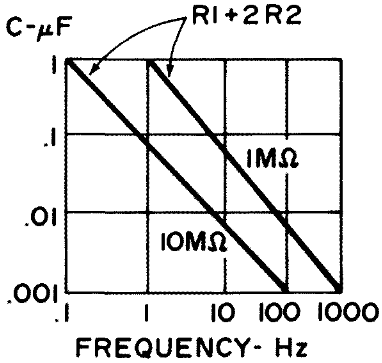

Fig. 4. Values of R_1, R_2 and C versus frequency.

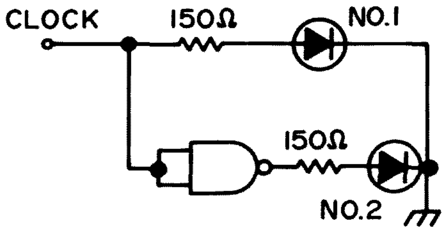

Fig. 5. 7400 IC blinker.

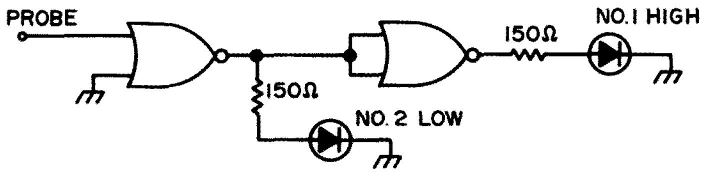

Fig. 6. Logic probe using NOR gates.

The Permanent IC Breadboard

When experimenting with ICs, we can find ourselves in a wire jungle. The innocuous 14 pin chip can strangle us in its spidery tentacles. The permanent breadboard will save us. It is simple to build and convenient to use. No excuses for non-IC experimenting will be valid after this article is digested.

Start with a perfboard. Allow about 4" x 3" for each socket that you want. Since most ICs are 16 pins or less, I decided to design the system around these holders. Punch a hole in the board and mount the holder. Since the holders will be subject to lots of wear and tear, I spread a thin film of epoxy around each one to hold it fast. Then, on each side mount the type of solderless terminals you prefer. I used the spring type terminals. They are amazingly sturdy and the spring can keep a large number of wires very tight. Solder each terminal to its respective socket lug and you are in business.

I also mounted two LEDs to use as testers and logic tracers. If you plan to work with chips of more than 16 pins, mount them. Keep in mind that a 16 pin socket can also be used for two 8 pin chips. Mount as many sockets as you want. A TO holder may prove helpful. Feel free to customize.

For a deluxe model, mount the power supply and clock in a chassis, but instead of a metal cover, use the breadboard. Mount terminals for Vcc, ground and clock output, and another for clock speeds, and voila! A self contained IC experimenter. All you will ever need in one unit.

As your chip collection grows, a safe way of storage is needed. Try putting the chips in a soft piece of styrofoam. The pins remain undamaged and notations can be made on the styrofoam with a pen. Sometimes chips come with "house numbers" instead of the usual 7400, 7402, etc. The notations keep track of these.

Don't Do Much

Readers have asked for simple schematics that teach logic even if they don't do too much. Now that the permanent breadboard is built, we can get started.

The 7400 chips are good ones to play with. Buy a few. Especially get the 7400 NAND gates, 7402 NOR gates, 7408 AND gates and the 7432 OR gate chips. This will give you the four basic gates to experiment with.

In Fig. 5 we have a circuit for a blinker. When the clock output is high the #1 LED lights. LED #2 sees low logic because the NAND gate makes its 1,1 input into a 0 output. When the clock emits a low, LED #1 stays off but LED #2 sees a high and lights. Cute, heh?

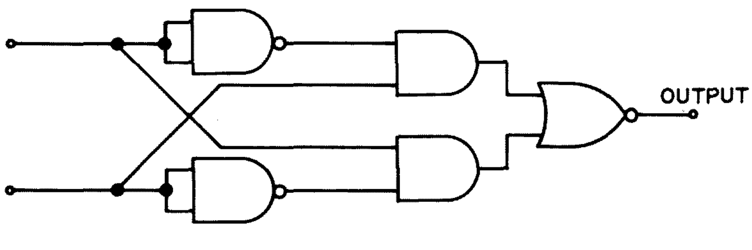
Fig. 6 is a logic probe. It's a long time favorite circuit and has been around for quite a while. (Dec. 74, *73* has another one.) It's a useful tool and *does* do much. You may want to make a permanent one. I include it because it's a good example of logic. When the probe contacts a high, LED #1 lights. For a low, LED #2 lights. The logic is simple to trace. It is similar to the blinker but it will not load down the circuit under test because the LEDs are not "seen" directly. Add this to the power supply, clock and breadboard, and you are all set.

Fig. 7 is a comparator. (Did you really think I would mention it before and not explain it now?) Its job is to compare two or more signals and if they are the same logic, give us a logic 1 output. Its logic is simple to follow. Keep in mind that it compares any similar signal 0 or 1. Instead of the NAND gates you can use the 7404 NOT gate chip. Try your hand at designing a comparator to handle more than two inputs using the two-input comparator as a building block.

If you have not already done so, try building a few of the flip flops that you have seen in the last article. They will work just as easily as these simple ones. From personal experience, I have had better luck with ICs than tubes or transistors. They are easier to trace and troubleshoot and either "work or don't work." There is usually very little optimizing and fudging as in tubes or biasing problems that you encounter in transistor circuits. And it's so much fun when the majority of your projects need only a 5 volt supply.

Please continue to write and tell us what you would like to see "explained." You are our input. ■

Fig. 7. Two input comparator.



De-Strain Your Ham-M

by
Louis Berman K6BW
1020 Laguna Avenue
Burlingame CA 94010

For the older model Ham-M Rotator, the final result is superior to the switching system presently employed in the newer model. The objective in both instances is to ease the torsional strain imposed on the rotating shaft and antenna resulting from the immediate engagement of the brake when power is removed from the rotor in the original version. This is done by momentarily delaying the brake action. The simple wiring change, together with the following instructions, should encourage even the lowest beginner to make the modification.

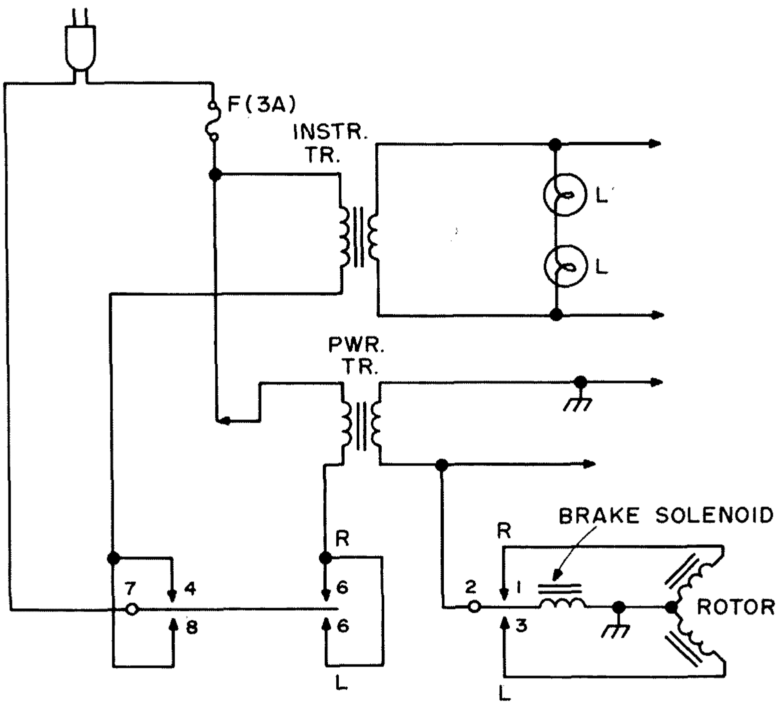


Fig. 1. Before modification.

Modification Instructions

1) Lift off bakelite housing by unscrewing the four bottom-mounting feet. Detach meter panel by removing the four screws holding it to the bottom plate. Disconnect the two meter leads. This frees the mounted bakelite component board from the meter panel bracket. Remove the meter. Unclip the two panel lamps. The control lever switch contacts are now fully exposed.

2) Screw back into position the bare panel bracket and re-mount the bakelite housing in place.

3) Drill a small hole in the bakelite panel 1 1/8" from each end of the panel front and 5/8" from the bottom edge. Pass the drill straight through each hole in a *direct line* and drill a hole in the meter panel bracket. Remove the bakelite housing and the metal bracket.

4) Enlarge the left hole in the metal panel to mount the push-button switch with the two contacts in a horizontal line. Enlarge the right hole in the metal panel to mount the miniature DPDT switch oriented so that the bat handle moves horizontally.

5) Disconnect the ac input lead from contact 7 of the lever control switch. Add about three inches and re-route the lead so that it passes to the right of the 3A fuse. Solder this lead to the left-hand contact of the push-button switch. (Control lever contacts are numbered from 1 to 8 in a clockwise direction.) Solder a wire between the left contact of the push-button switch to *both* middle contacts of the DPDT switch.

6) Remove the instrument transformer lead from contact 4 of the lever switch and solder it to the right-hand contact of the push-button switch. Leave enough lax in the wire to provide working space between the meter panel bracket and the control lever.

7) Solder a wire between the right contact of the push-button switch and one of the "on" contacts of the DPDT switch (brake out position I).

8) Disconnect the power transformer lead from contact 6 of the lever switch and solder it to the other "on" contact of the DPDT switch (brake out position I). The other primary lead of the power transformer goes to the 3A fuse, as shown in the diagram.

9) Lever contacts 4, 8, 6, 7 are not used. Contacts 1, 2, 3 remain to actuate the rotor; contact 2 also completes the brake solenoid winding circuit.

10) Check the wiring carefully and remount all parts except the bakelite housing.

Test Operations

1) Push-button momentary switch lights lamps and monitors the compass reading.

2) Double pole double throw switch is left in the "off" (brake in II) position when the unit is not in use; panel lights are off and brake is engaged to secure the rotor.

3) To rotate the antenna, snap the DPDT switch to the "on" (brake out I) position; panel lights are on and brake solenoid is actuated, releasing the brake. Moving the control lever to the left or right energizes the rotor and permits free CW or CCW rotation.

4) Release control lever just prior to reaching intended compass position, permitting the unit to coast to a full stop. Snap DPDT switch to the "off" (brake in II) position to lock the rotor and turn off the panel lights.

Housing Removal

The following steps permit lifting the bakelite housing vertically (as before):

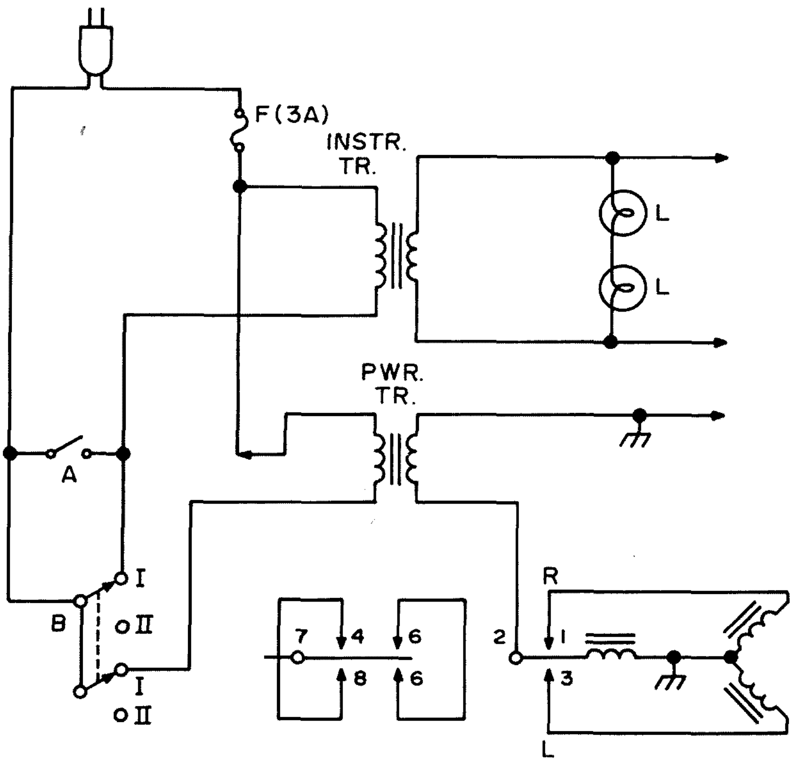

Fig. 2. A — Push-button momentary switch; B — Miniature double pole, double throw switch; I — Brake out; II — Brake in.

1) Enlarge the left hole in the bakelite housing to admit a removable hollow shaft extender to fit snugly over the button of the push-button switch. I used an old TV hollow shaft slotted at the open end, with a small knob at the other end.

2) Drill out a horizontal slit in the bakelite housing at the right-hand hole wide enough to admit a removable lever. I used a one inch length of 3/16" copper tubing, slightly compressed at one end to fit over the bat handle and flattened at the other end to facilitate lever movement.

3) Impress the following labels over the appropriate holes on the horizontal ledge above the fluting: "meter-push on" and "brake-in out" (or "brake-out in", whichever the case may be).

4) As an added refinement, mount an octal socket in the rear on one inch standoffs and permanently connect the output leads to the pins of the octal socket. The cable leads are soldered to the appropriate pins on an octal plug for easy removal of the cable.

In summary, to reverse an old adage, the entire modification is easier done than said! ■

There sitting on the curbstone was the most beautiful telephone microphone I'd ever seen. Soon it was under my coat, as I rapidly pedaled away . . .

During World War II our military had an expression that was widely used: "to liberate" meant to help yourself, particularly if the stuff was enemy property. All too often, if not most of the time, anything attractive that belonged to someone else, enemy or not, was subject to liberation if the owner was not around or happened to be looking the other way.

I started rather young, long before the war. Someone said there's a bit of larceny in all of us. Probably W. C. Fields. Anyhow, I was coming home from school one afternoon on my bicycle when I saw a great cloud of dust rise up near our apartment building in Washington, D. C. Wreckers had just leveled an old house, which had come crashing down.

There sitting on the curbstone was the most beautiful telephone microphone I'd ever seen. It was one of the old vertical jobs with the U-hook for the receiver earpiece. A lovely bright green cord was coiled up and hung over the mouthpiece. What in the world was it doing there, I wondered.

This was no occasion to elaborately reason out that the workmen might have left it for the telephone company to pick up. It was much easier to assume they would soon fling it in their dump trucks, which were rapidly piling high with trash. Such waste would be awful.

I took a furtive look in all directions. Suddenly the beautiful microphone was no longer on the curbstone. It was under my coat, as I rapidly pedaled away.

Thus, that mike with the bright green cord began its journey into history.

A couple of years passed. My father's engineering career involved our moving several times. But wherever we went, that mike sat on the table near my radio apparatus, where I could look at it and admire it. Soon I had my ham ticket and found myself president of the Phillips Academy, Andover, Radio Club – NU1SW.

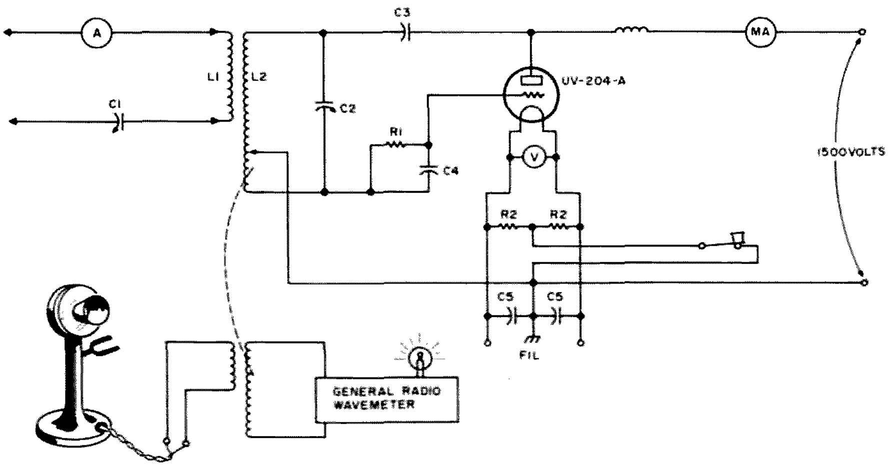

Fig. 1. 1927 Hartley circuit DX machine at NU1SW. For anyone who wishes to build this magnificent transmitter, we will be pleased to forward a list of component values and recommended hardware. Simply send us $5.00 and a copy of the New York Times *for Sunday, April 1, 1956. You will receive the information in a plain wrapper.*

(We had no official international prefixes in those days. We all had accepted an ARRL system: N signified North America and U, the United States.)

Naturally, my beautiful mike sat proudly but silently next to the CW transmitter. NU1SW's 204-A, in a self-excited Hartley circuit, had become a big deal on the 40 meter band, with about 30 countries to our credit by mid-winter, 1927. But this was all night-time stuff, mostly to be had in the wee hours of the morning. With 1,500 volts RAC on the plate at 190 mills, we were putting out enough rf in the antenna to draw a one half inch spark off the feeder wire with a lead pencil. That was a dandy way of checking the output in those days.

Well, snow was falling one Saturday afternoon, and a howling New England gale was slapping our antenna halyards against the 60-foot poles. The ham shack was nice and warm, with a banked wood fire in the iron stove. Everything was fine, but the 40 meter band was dead – just about completely, except for WIZ, which was on Cape Cod, I believe, a commercial CW outfit at the edge of our band. WIZ would send a trilogy of Vs, sign his call – and then repeat ad nauseam. This was too much!

Why not try 20 meters, which was getting very popular? We had never operated there before – or even listened on that band. My friend Gerald Marcuse EG2NM (E for Europe, G for Great Britain) had been broadcasting with voice to Australia and New Zealand around 32 meters for several years – with grand success.

It didn't take long to halve the 40 meter inductance for the rig and to change coils in our General Radio wavemeter. The capacitance of the tank coil condenser (variable capacitor to you young laddies) was fortunately okay to resonate the oscillator coil on 20, so that the wavemeter indicator bulb lit up like a stockbroker's eyes when he smells money.

The wavelength readout, as you guys might call it, was 20.9, or 14.354 MCS – Quite legitimate in those days. Antenna? It was much too cold to go outside and fiddle around. I had that one figured out, too. Hopefully. With indoor space limited to just about 16 feet in any direction, I soon had a copper wire strung up at about that length and coupled with a 250 uF condenser to a four turn coil adjacent to the plate side of the oscillator tank. Oh, boy! The contraption loaded up just fine. Backing off a bit with the antenna coil, the plate mills were steady at about 190, with the 204-A running as cool as a cucumber with the key down. Probably 125 Watts output. This was it – maybe!

Our Phillips Academy Radio Club in 1925. Only four years earlier the first amateur radio signals had bridged the Atlantic and then spread out over the globe. Between 1925 and 1929, 1SW, first with no prefix, then with U, later with NU and finally with W, was known from New Zealand to Tokyo, from London to Capetown. The school faculty, including our "advisor," who never put foot in the shack to my knowledge, had us cased as a bunch of scientific freaks. It's good to know that the W1SW boys have been doing nicely in recent years, with a more enlightened group of schoolmarms hovering in the background.

Tuning over the band at 2:25 pm, I heard no signals. So I hit the key with a CQ, slow and steady – which was top style to snag DX. Then, flipping over to receive, there was only the gentle hiss of radio silence – until suddenly, as I moved the dial across the band, a very strong signal popped up, calling us. Probably a local, we thought, until he banged out his call: EG2AO. The call book gave his location as Eastbourne, on the channel coast of England, in Sussex. And daylight nearly all the way across! "Good afternoon, old man," he CW'd at me. "Your signal's fine business. Very steady RAC, almost PDC."

After I gave him his report, he continued, "Say, old man (I was 16 years old), your signal's the best yank ever heard here, nearly as strong as WIK (a 10 kilowatt commercial station on 20.2 meters)." We had a delightful QSO, winding up by his saying, "Am now reading you on the loudspeaker. Wonderful!"

As we signed off, I found myself staring at my beautiful microphone with the bright green cord. Why not? Why not try some voice on these guys?

Having no modulator of any sort, the only answer was to make up a crude version of FM known as loop modulation. In short order I'd rigged the mike inductively to the wavemeter, which I placed near the grid end of the tank coil. But not too near. There was lots of rf floating around.

A tentative "hello test" into the mike made the wavemeter bulb flutter in sync and the plate milliammeter wiggle a few mills upward. It was a durn good thing there were no television sets around.

My little liberated microphone was making history, at least for us . . .

Now to find a guinea pig for my experiment. A CQ DX on CW brought quick response from EB4BC in Antwerp, Belgium, who reported us loud and clear. "Sure, go ahead with fone," he replied, when I told him of my wild modulation device. So I let him have it at some length, watching the little wavemeter bulb twinkling with my words.

Then I switched back to him. "You talk too fast, old man. Don't understand English well. Please say a few words in French." Fortunately I was able to comply, which brought forth an excited "fine business," with many CW exclamation points.

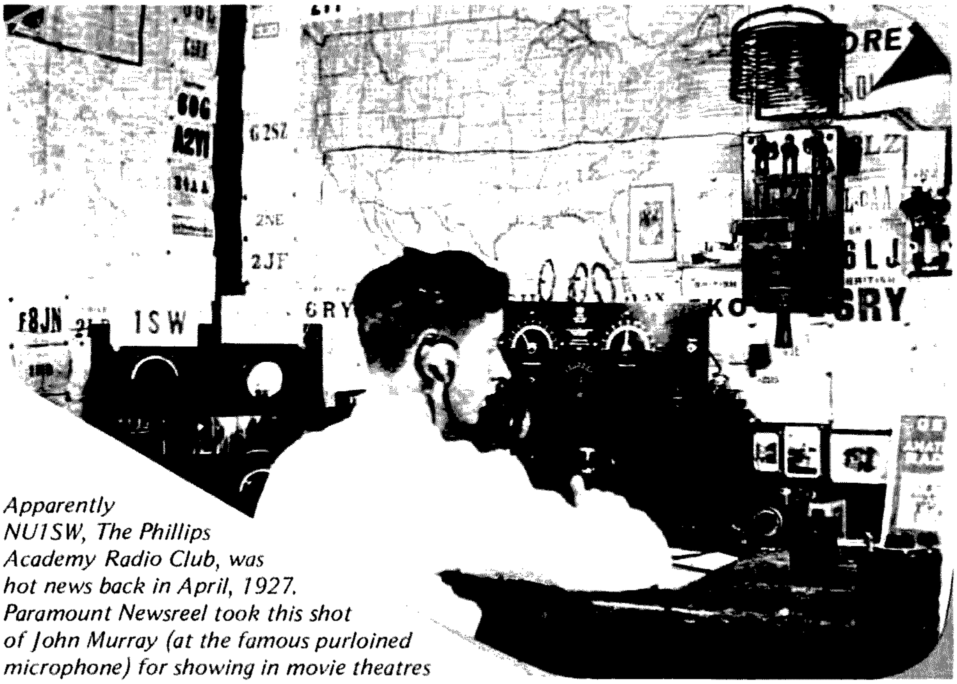
For some time I continued with him, watching the snow coming down in great sheets outside. This fone business was really fascinating – one could say so much more in a given amount of time. Also, my little liberated microphone was making history, at least for us.

Several other club members had joined me by now. We were all amazed at our success and anxious to get some really big DX on voice. The Belgian station was about 3,400 miles away. What about Africa – or even Australia? So we sent out a CQ DX on voice, repeating several times. "Calling Africa or Australia," I sang into the mike. It was a superb bit of optimism that had us all but breaking up.

And then, suddenly, there was F0-A3Z in Capetown, South Africa, calling us. He was on CW with a good strong signal. We'd worked him before on 40 meters. He was about 7,800 miles away. Real DX.

"Your voice loud and clear in Capetown," he said. "Congratulations. First American amateur voice signal ever heard here! Glad to work you again."

We thanked him, giving his report – and explained what the modulator lash-up was. About then I noticed a thin wisp of blue



Apparently NU1SW, The Phillips Academy Radio Club, was hot news back in April, 1927. Paramount Newsreel took this shot of John Murray (at the famous purloined microphone) for showing in movie theatres nationally. To the right is a General Radio wavemeter. To the left is our low power transmitter, an 852 self-excited Meissner job. The cameraman insisted on hanging that crazy, obsolete switch and huge old RCA helix coil on the wall for "artistic effect." The double deck receiver lash-up has a honey coil job on top, which REL (Radio Engineering Laboratories) built especially for us, designed and donated by the late fabulous Henry B. Joy (W)8IA, 8IO, IAHM, KFKW, at that time president of the Packard Motor Car Company. Beneath it is an Aero regenerative receiver, both units battery operated, of course, since there were no ac powered sets in general use at that time.

smoke rising up from the microphone. Hurriedly we turned it back to him.

He reported everything fine up to the tail end of our transmission. "Bad distortion then set in," he said, "and your transmitting frequency really jumping around."

When I turned on once more to reply, blue smoke gushed from the mike. If this continued, the carbon grains would solidify in a ball. Quickly shutting off things, I moved the wavemeter a bit further away and detuned it slightly. Then, holding the mike by its shaft, I banged the daylights out of it on the bench.

"You're out of your mind," one of the boys said. "You're going to bust that thing."

So, I gave it a couple more whacks to show I knew what I was doing, then switched on the transmitter. "Calling F0-A3Z," I said. "Are you still there?"

"Lovely," he came back in his CW, "just lovely. But your voice much weaker now."

Then, all of a sudden, I felt as if someone had slammed me in the back of the head with a wet doormat. I began to ache all over and broke out in a cold sweat. Our 2nd op, Bob Schirmer, signed off fast with the South African. "You'd better get down to the infirmary right away," he said. "You're red as a beet."

It wasn't easy. However, he managed to help me walk the half mile and turned me over to the head nurse, Mrs. McKiver. She took one look and had me guided to a first floor bed. I never could have navigated the stairs and was by now, they reported later, not making any sense. My temperature was 105.4°. Emergency word got the school doctor on hand in jig time. He couldn't find anything wrong except my high temperature. Fortunately, it was not increasing.

Dr. Page was not noted for his sense of humor. A serious-minded little guy, he had three pet phobias: With no urging at all, he was ready at any given moment to preach on the vicious evils of tobacco, alcohol and coffee. Mrs. McKiver told me later that my greeting, when he showed up at my bedside, was hardly liable to put him in a good mood.

"Hello, sweetheart," I said. "You got a cigar on you?"

He surveyed me coldly for a moment, then raised an eyebrow. "You been drinking?"

"Sure, Doc, that's right. Maybe I need a cup of black coffee. No sugar, please."

He seemed to catch on, turning to Mrs. McKiver. "This boy's delirious. I've got to find out what he's been up to." He sat down on the edge of the bed, grasped my wrist and took out his watch. "What have you been doing today, young man?"

"Just some radio experiments you wouldn't understand – and floating out over the South Atlantic Ocean on a dreamy cloud, sweetheart, and going like hell – about 186,000 miles an hour."

Dr. Page looked at Mrs. McKiver. "Cool compresses on his forehead, please. I'll be back later." Then he prescribed a mild sedative.

In almost no time I was off in a fevered sleep which lasted for several hours. When I opened my eyes he was back again, shaking a thermometer. I was now just about normal – but with a jagged headache.

While I was floating around on my cloud, he'd been doing some hasty consulting with two other local doctors and had even called the Peter Bent Brigham Hospital in Boston. "Your trouble has something to do with radio currents," he said. "Somehow your system has absorbed a dangerous dose of these radio frequencies – giving you an artificial temperature which could have killed you if you'd gotten much more of it."

Then I explained the tests we'd made and the smoking microphone. His careful questioning brought out that my hand had been on portions of the unshielded microphone cord and also had held the shank of the telephone for an unduly long time. I'd just been overly exposed to a force I really didn't know anything about.

"I believe," he continued, "if you were about to come down with any of a number of different illnesses, you have killed the bugs, luckily not yourself to boot. A rise in temperature is nature's way of combatting unnatural intrusions and infections. In your case, there was only one bug involved, a radio bug – you. You'd better be more careful."

His advice was well taken. Dr. Page was a lot more thorough than I had imagined. It was not until several years later that the medical profession was experimenting with artificially induced radio frequency fevers to help in alleviating certain infections, notably pneumonia. A New York doctor told me that a government hospital had achieved significant results in this respect. Furthermore, it had been determined that there was a definite cut-off point beyond which the human system could not take these artificial fevers, somewhere in the neighborhood of 106°. Just a few more QSOs that afternoon would have cooked my goose, somewhat the same way that the microphone with the beautiful green cord got cooked.

So-o-o ... the next time you see a telephone with a beautiful green cord sitting on the curbstone, I suggest you leave it there. ■

All of a sudden, I felt as if someone had slammed me in the back of the head with a wet doormat . . .

Just a few more QSOs that afternoon would have cooked my goose, somewhat the same way that the microphone with the beautiful green cord got cooked . . .

EDITORIAL BY WAYNE GREEN

from page 3

to some of the restaurants . . . and chew the rag about ham radio on into the evenings, drop a line or call me and let me know. The group rate is a real bargain . . . runs about $150 or so for the week for the hotel and lift tickets, plus $50 for lessons, plus meals. You only live once, so get out and join a fun group for a week. Don't forget to bring an HT with 52 in it, even if you have to borrow one . . . and a charger too.

When you prepay for this deal you are eligible for reduced rate air fares. From Boston it cuts the cost from $276 RT to $207 . . . not bad. It'll probably give you a good cut from where you are too. Please let me know as soon as you can about this so I can make reservations. Call Wayne Green at 603-924-3873 or write c/o *73 Magazine.*

FCC – PROFOUND CHANGES

For the last few years I've felt that I was trying to shovel coal up a shute, to coin an expression which youngsters probably won't understand, having never watched coal being delivered to homes.

Amid cries from many amateurs not to rock the boat, you can't fight city hall, etc., I have been making what seemed to me to be futile suggestions about de-regulating amateur radio. When Walker wanted to go to even more license classes I sighed and filed my protest in an editorial. When Walker came up with the repeater rules I cried out in anguish and got together a group of amateurs to take the complaint to the boss: the FCC Commissioners. One of the most attentive ears at that hearing in January 1974 was now Chairman Wiley . . . who seemed to be enthusiastic about the idea of freeing amateur radio from restrictions so amateurs could invent and experiment without having to file in sixteen copies, complete with a six months or longer wait.

Whether my constant nudging had any effect or not, it does appear that we are going in the direction that I have been pushing . . . de-regulation . . . fewer license classes instead of more . . . getting rid of the growing welter of restrictions. I'm almost afraid to tell you the extent that this thing may be going. There is a strong movement deep within the FCC to set up basic guidelines . . . concepts, as it were . . . and then get rid of all the mass of rules.

Could you deal with a situation where all repeater rules were taken off? Where it was up to us as amateurs to make sure we have coordinating groups and that all repeaters abide by the coordinators? I wrote about this last month. This would mean that we could, if we wanted and the coordinators were in agreement, set up 10m repeaters . . . crossband repeaters . . . 20m to 220 MHz repeaters, etc. We could use timers on them, if we wanted . . . or not.

People generally tend to group in positive or negative reactions to change . . . the positive tend to view problems in terms of solutions . . . the negative in terms of why you just can't do things. I suspect that should these changes come to pass that we'll have a lot of reaction of both kinds . . . which will you be, a positive or a negative?

What about sub-bands? With the rules out the window we would be able to use any mode on any part of any band . . . yes, I understand that this is absolutely impossible . . . to answer the negatives. But perhaps with some basic guidelines it could work. It sure would be nice to be able to use SSTV and RTTY on the same frequency . . . I think they'll go together well . . . both can be stored on cassettes . . . both work via computers, etc.

Fundamental changes such as this will take a good deal of time. Let's see if we can't be a help by thinking and talking about how we could set up a minimum regulation system which we could live with. Do we need two or three classes of license? One thing I do know, if we de-regulate substantially this will mean a lot more for the ARRL to do, for we will need to have organization to get cooperation . . . and without cooperation we have only anarchy.

The FCC is not unaware of the impact of delays on licensing and they have in mind a little strategem which might help . . . they may make it so that once you pass your exam you can immediately go on the air with the higher privileges. This will make it possible to hear a Novice call in the Advanced band, which might be too much of a trauma for an official observer. If they do away with subbands and merely set power limits for the license classes, then this might not make much difference. I do kind of like the Japanese system of letting beginners operate on all bands limited to ten Watts.

One of the major reasons the FCC is having such a time catching up with the licenses, as you know, is the backlog of CB applications. Just put on more people to handle the pileup, you suggest? Any reasonable businessman would say the same thing . . . but the FCC is run by Congress and not by businessmen, and it appears that Congress could care less how much money the FCC is raking in with their CB licenses . . . and the profit is enormous on them since the *only* service they provide is a piece of paper. Congress is trying to cut down on the staff of the FCC, even though every dollar saved in salary will probably cut income by hundreds of dollars. That's the Congress we all know and love.

The Commission is afraid that if the CB licenses are not promptly processed that more and more CBers will just ignore the FCC and not bother to spend the $4. In point of fact there is little reason to spend the money and Congress would do well to take advantage of the naivete of the CBers and take their money as fast and quietly as they can.

COMPUTER BIZ IN PERSPECTIVE

One of the results of my work in the microcomputer field is that I have been in contact with most of the firms producing or developing gear for this field. It has been, to say the least, fascinating.

Amateurs who are feeling twinges of inferiority because they are unable to understand the jargon should take heart. The computer biz is brand new and no one has much of a jump on you. Don't let a few buzz words drive you under the table . . . when they say interface all they mean is that two things are connected together . . . it's all like that and with a little reading you'll be able to go to the next club meeting, sidle up to the resident computer type and watch with glee while a growing circle of eyes pop out at your infinite knowledge.

News flash: Microcomputers are so new that hardly anyone anywhere has them working yet. If you have a few drops of pioneering blood left in you after all that appliance operating, here is a field where you have an equal opportunity.

There are some good economic reasons for getting into the field . . . beyond the fun involved. In a year or so, when the pioneers in this field have systems that work, they are going to be able to sell and service them by the zillions. Experience has shown that once a home computer system is set up and running it gets used . . . a lot. Kids quickly get into playing games with it and soon put the old man to shame with innovative programming. The computer gets a lot more use than television.

The really big market for them will be for business. Every small business will be using one . . . and that means sales in the hundreds of thousands of units. This won't happen until the pioneers develop good working systems which are adapted to each type of business.

Most computers today are being sold directly by the manufacturers and I look for this system to fade out as truly large scale merchandising takes over. It will require local computer sales, programming and service stores to handle the growth. And who would be more logical to open such a store than the computer hobbyist of today?

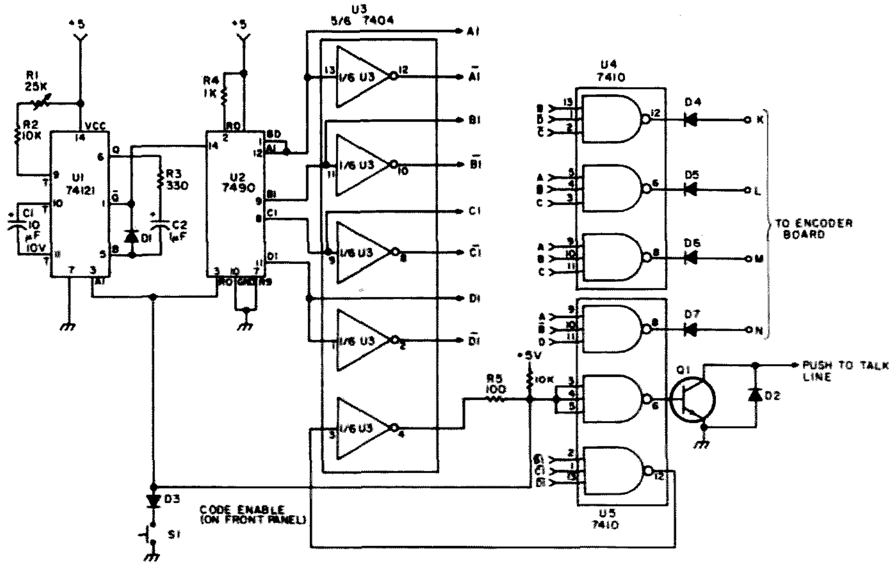

Fig. 1. Code access board schematic. D1-D7: 1N914; Q1: 2N3904 or equivalent. Note: Increase R2 for slower dial rate.

With many autopatch facilities being added to repeaters around the country, it is becoming easier to keep in touch from an automobile with friends, family or various public services. Expensive mobile phone or RCC services are no longer needed for casual conversations. Many amateurs are adding touchtone encoders to their rigs, either in the form of a single box which plugs in to the mike jack on the radio or more elaborate wired-in units which are permanently mounted to the dashboard. Making an autopatch is then easy – one only has to push one or several digits to access the dial tone, then dial a number. However, safeguards on many repeaters dictate that an access code be dialed within a certain time limit, and then the complete seven digit telephone number be dialed within another short time limit. If these times are not followed, the repeater controls will disconnect the circuit to avoid tying up a phone line.

To follow these prescribed limits while moving in heavy traffic is unwise. Many accidents or near misses have occurred when

The unit is a pleasure to use and also functions as a conversation piece, for every time it has been used, someone wants to know how I learned to let my fingers walk so fast through a touchtone pad . . .

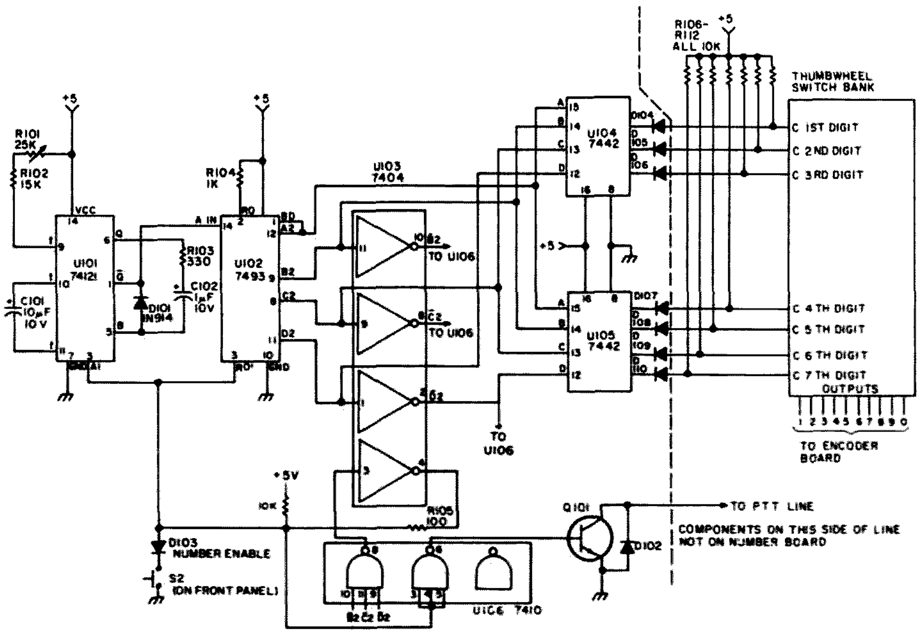

Fig. 2. Number counter board schematic. D101-D110: 1N914; Q101: 2N3904 or equivalent. Note: Increase R102 for slower dial rate.

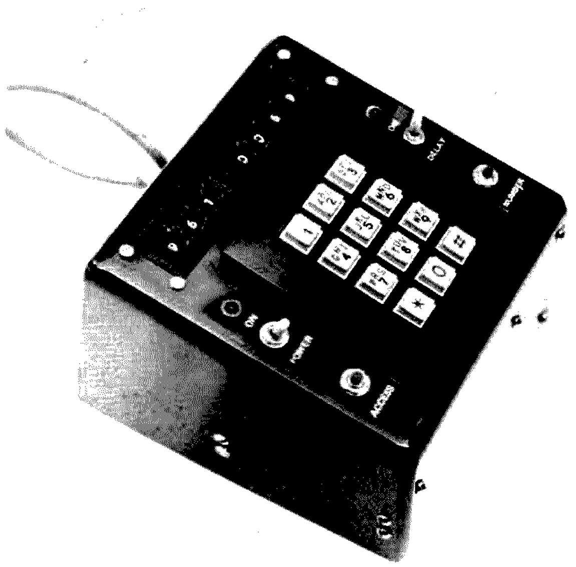

amateurs have tried to dial while in motion. In this area, a four digit access code must be dialed within 3 seconds and the complete 7 digit telephone number within 7 seconds. With these facts in mind, the pressure to get the sequence correct dictates that full attention be paid to the push-button switches and not to the road. Not wanting to pull over to the side in heavy rush hour traffic or on bumpy under-construction interstate highways in this area, I have invariably dialed a wrong number or had several near misses in the short time my attention was diverted.

I decided there must be an easier and safer way. It was relatively mundane to push one button without looking rather than concentrating on pushing several in proper sequence. After investigating the possibilities of surplus card dialers (there aren't any) and the feasibility of tape recorded touchtones (it's too hard to find the number), I decided to put my dubious education to work.

Obviously, some sort of ripple-through counter was needed for the repeater access code and number to be dialed. Some way of programming any required number was desired, along with an appropriate touchtone encoder to interface with the logic and transmitter. The repeaters in this area (there are five with autopatch) had several requirements, both technical and

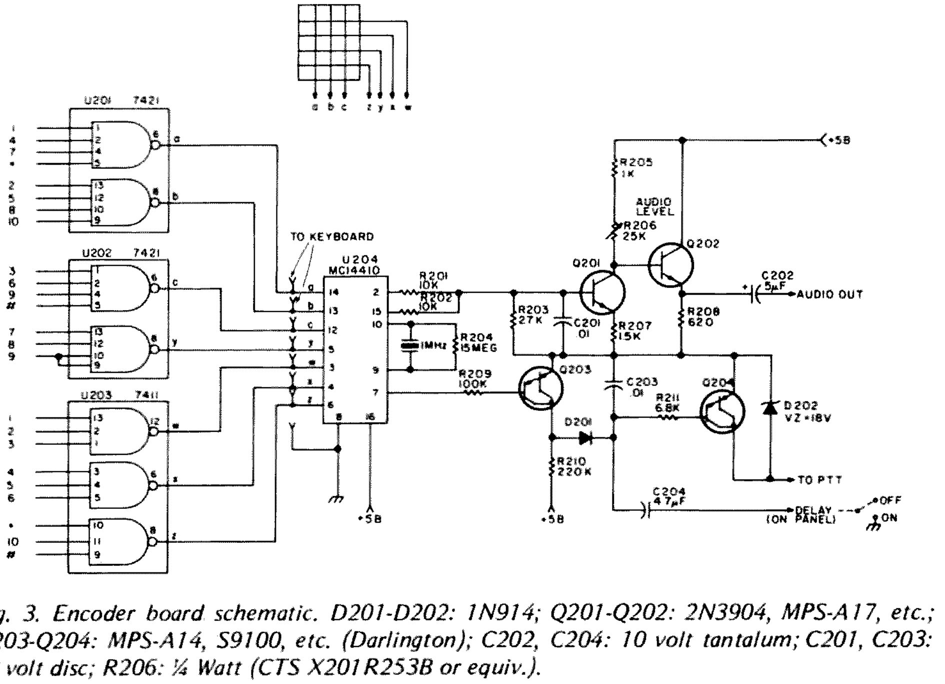

Fig. 3. Encoder board schematic. D201-D202: 1N914; Q201-Q202: 2N3904, MPS-A17, etc.; Q203-Q204: MPS-A14, S9100, etc. (Darlington); C202, C204: 10 volt tantalum; C201, C203: 50 volt disc; R206: ¼ Watt (CTS X201R253B or equiv.).

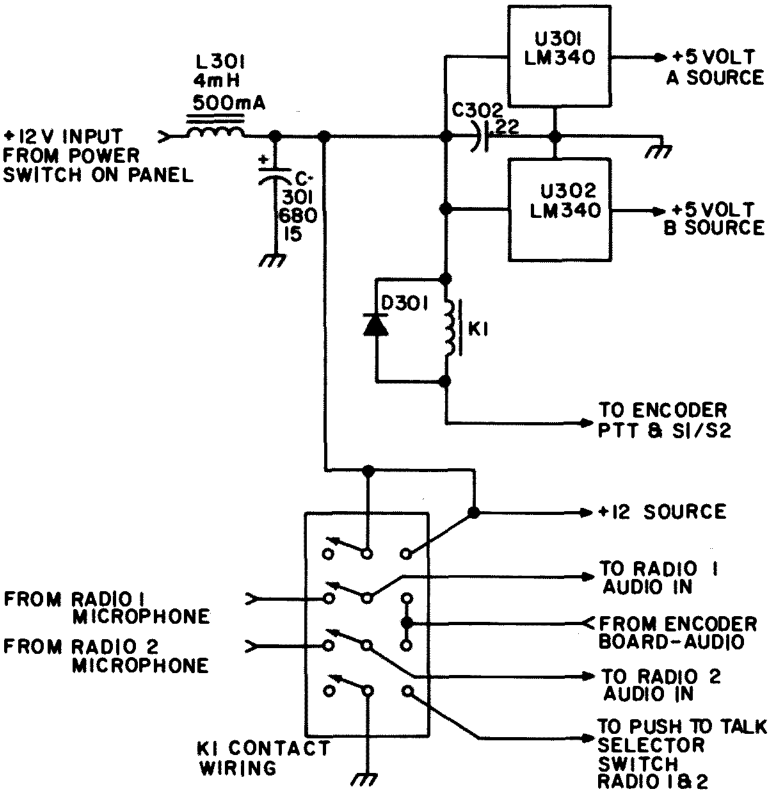

Fig. 4. Power supply and switching arrangement for 2 radios. D301: 1N914; K1: 4PDT 12 V Magnecraft W77CSX-2.

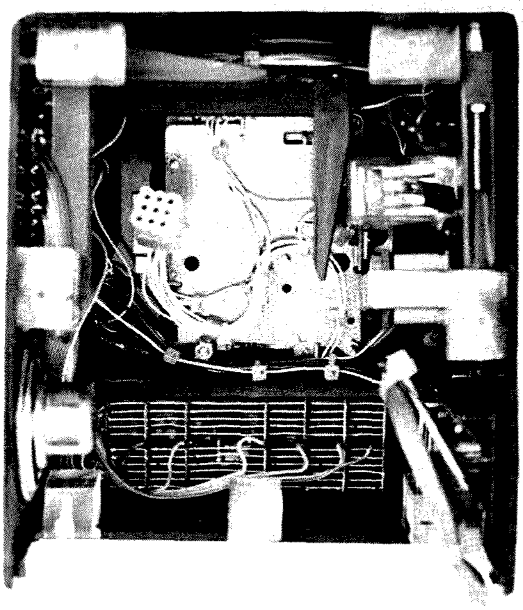
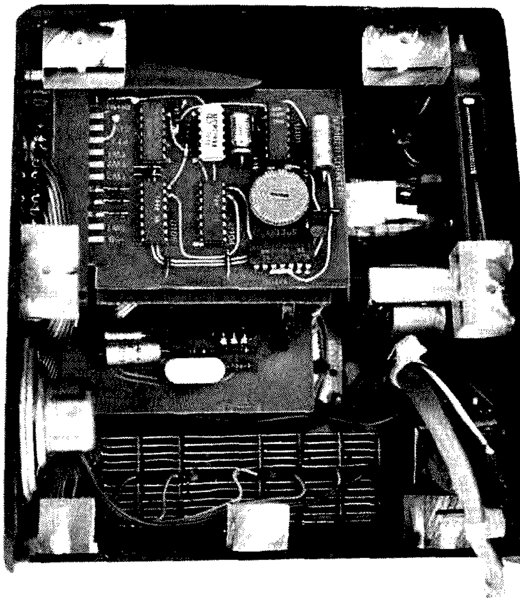
administrative: Deviation should be within certain limits (4-5 kHz); no clipping is allowed; the four digit access code must be dialed within 3 seconds, and the complete number within 7 seconds. The administrative procedures dictated that you: (1) Announce your call and intention to make an autopatch; (2) Let the repeater tail drop to reset the agc; (3) Key in the access code and let the transmitter drop for dial tone; and (4) Dial the number. To hang up, any button on the touchtone pad is depressed. Thus, one button to dial the entire 4 digit access code and one button to dial the seven digit number would be needed. Also, a switched ground on the push-to-talk line would be desirable to key the transmitter automatically. For proper impedance matching, the microphone circuits should disconnect and the encoder tones be fed to the audio input on the transmitter, instead of placing both in parallel. Since it would be desirable at times to have a manual entry, a 12 button keyboard should be included. The memory device could be ROMs, PROMs or such, but an easy interface was found to be thumbwheel switches, both for simplicity and to keep the project from getting away from me.

I finally devised the circuits of Figs. 1, 2, 3, 4 and 5. This gives both the capacity of letting the circuit dial the described number or enabling it to be done manually. Operating it is quite simple and takes about 2 to 3 seconds. The procedure is as follows: While stopped at a light or doing one-at-a-time as my attention to driving permits, I set up the telephone number on the thumbwheel switches as I want it. I then key the microphone and announce I am going to make an autopatch. After the repeater tail drops, I push the "access code" button. Immediately, the transmitter keys and the 4 digit access tones are transmitted. The transmitter goes off and I hear a dial tone. Then I push the "Number Dial" button and the same process takes place. The telephone line starts to ring as the transmitter unkeys. After the conversation, I manually depress the hang up number on the keyboard and clear the repeater. So far, the only time-consuming procedures have been the explanations to other hams who call me after the patch to find out how I can dial a number that fast.

The circuit is essentially two counters with separate enable switches. The first is comprised of U1 through U5 and is for the 4 digit access code. If your repeater has just one access digit, this circuit is not needed and you may just as easily use the keyboard. But if 2, 3 or 4 digits are needed for access, the K, L, M and N outputs of the code





Two internal views.

access board may be easily programmed to accomplish this.

The second counter is similar, but counts higher for a 7 digit phone number and runs faster than the access code counter. Seven output pulses are fed to the seven thumbwheel switches, which "choose" an input on the tone encoder board. To the appropriate inputs are also connected the K, L, M and N outputs from the code access board.

To generate the access code, switch S1 is momentarily depressed. This keys the transmitter by grounding pins 3, 4 and 5 of U5, thus driving Q1 into saturation and grounding the internal push-to-talk line. Since the A1 pin of U1 is now low, output pulses appear at pin 1 and are fed to U2, which begins to count to 10. After 2 pulses from U1, pin 12 of U5 goes high and is inverted to a logical zero, holding U2 and U1 on so that S1 can be released. U2 provides a binary count from 0 to 9 and the A, B, C and D outputs are applied to inverters U4 and U5. These gates are wired in such a way as to provide a sequenced output of K, L, M and N with a space in between (see Table 1). After U2 counts to 9, it goes back to 0, which is the reset condition; pin 12 of U5 goes low and its inverter goes high, disabling U1 and holding U2 in the reset condition. As U1 and U2 are reset, the push-to-talk line is unkeyed and K1 returns to its unenergized

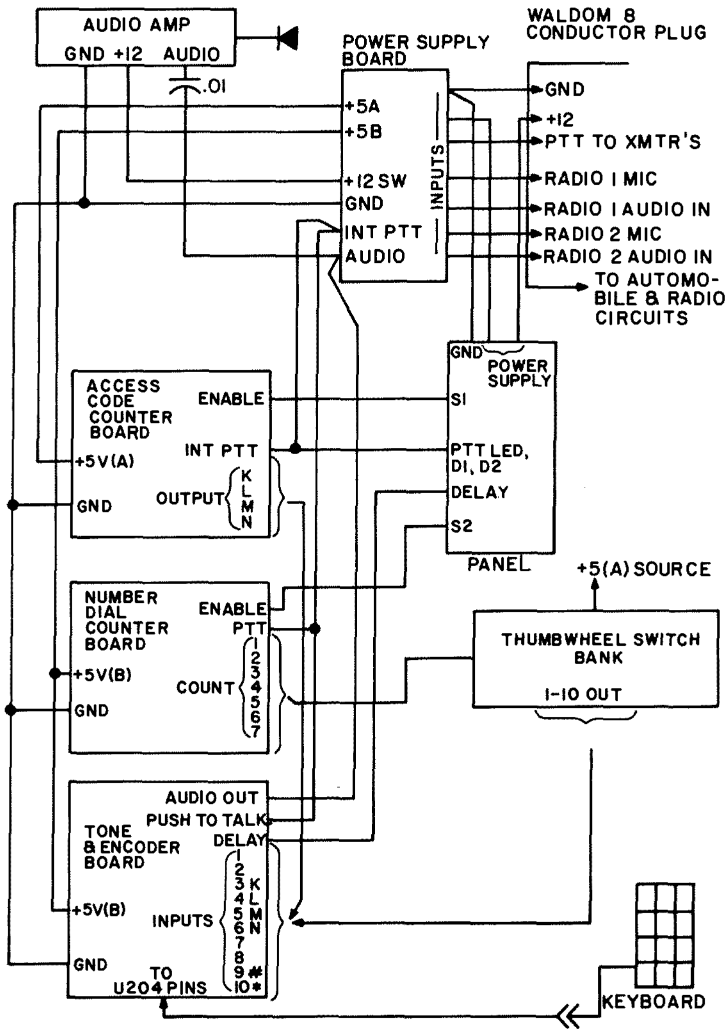


Fig. 6. Circuit board interconnection diagram.

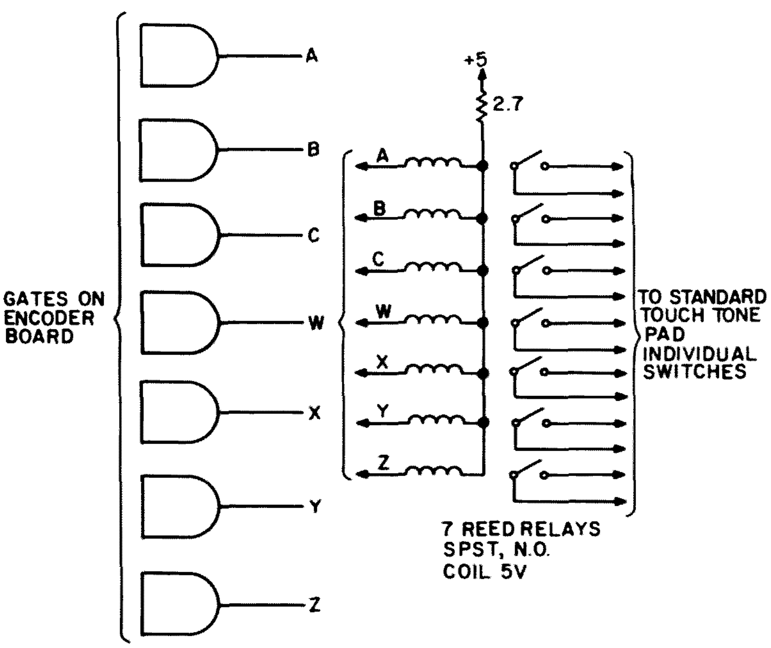

Fig. 7. Alternate method of generating tone. While quite cumbersome, this is a way to interface automatic circuitry to an existing pad. Outputs from reed relays are wired in parallel across existing pad switches.

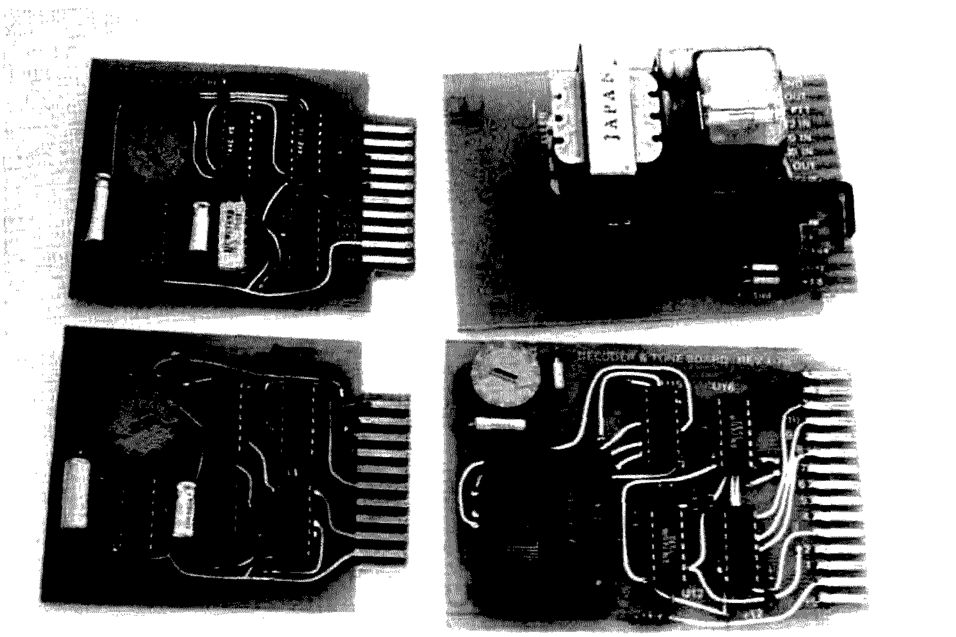
Etched and drilled PC boards as shown in this article are currently available from M-Tech Engineering Inc., Box C, Springfield VA 22151.

position. Because many repeaters require the first digit to be held longer than the others, the K output has been made 2 clock pulses long.

The K, L, M and N outputs are all logical zeros and are hard wired into the appropriate numbers on the encoder board. If no code is required, or if it is just as simple to push a single access tone, the access code counter board may be completely omitted.

The speed of the sequenced K, L, M and N outputs may be adjusted by changing the speed of clock U1, which is easily accomplished by control R1. If some repeaters need a faster pulse than is available, the 10k resistor (R2) in series with this control may be reduced or omitted. Conversely, a higher value of R2 will produce a slower speed.

To generate the telephone number, a separate similar circuit is used. U102 is wired to U104 and U105 in such a way as to count to 16 (see Table 2). The B, C and D outputs are inverted and fed to a section of U106, which provides the same controls as on the code access board, resetting U102 and disabling U101. U104 and U105 provide 7 logical 0 outputs which are wired into the common terminal of each thumbwheel switch. These logical zeros are routed through the switches to the appropriate inputs on the encoder board. As in the code counter circuit, the speed is fully adjustable with control R101.



The four PC boards. Clockwise, from upper left: number counter, power supply, encoder, code access.

Table 1. Truth table, access code circuit. When S1 makes R_0' and A_1 low, U1 provides pulses to U2. At each pulse, U2 counts from 0 to 9 in binary form. The enable switch S1 is held for 2 counts. When the reset line goes low, S1 may be released. At the 9th count, U2 returns to 0, which is the reset condition. If S1 has been released, R_0' and A_1 go high, resetting U2 to 0 and disabling U1. As the sequence progresses, the K, L, M and N outputs go to logical 0s in turn.

It should be noted that either of the 2 enable switches, when depressed, will cause the transmitter to key and tones to be sent. If either of their respective clocks is running very fast, some means of monitoring the tones should be present. Too fast a clock rate will result in 2 or more sequences or "bursts" of tone to be sent as the enable switch is depressed and then not released fast enough. LED indicators are convenient (more about these later) but a small, pre-assembled $2.95 Radio Shack 100 mW amplifier was used in the prototype, with a small speaker. Muted tones are heard as the unit sequences. This is also handy in checking the overall operation every time it is used. Instead of using a volume control, 2 resistors were chosen to take the place of the suggested pot and wired in place to the foil side of the amplifier.

The tone and encoder circuitry consists of seven AND gates in 3 DIP packages, which drive the appropriate inputs on a fourth chip, U204. Fig. 3 shows the wiring. The K, L, M and N outputs of the access code board are wired (in that order) to the required numbers on the encoder board. Two or more access code boards may be paralleled for up to as many different access codes required. If your system uses 1, 2 or 3 digits for access, any one, two or three of these access code board outputs may be hard wired onto the proper pin of the tone and encoder board connector in parallel with the thumbwheel switch outputs. The transmitter in this case will stay on for the full count of four. Likewise, the 10 outputs from the thumbwheel switches are connected to their respective numbers, 1-10.

When one of the encoder board inputs goes low (i.e., is grounded), the outputs of the gates involved go low also, driving the proper frequency pins of U204. U204 is coupled through two 10k resistors to a buffer amplifier to provide approximately a 0.9 V P-P max output. This output may be varied by an audio level control for deviation adjustment. The circuit as shown has a 600 Ohm impedance. For transmitters with a high impedance mike input, a resistor of between 50k and 220k should be placed in series with the 5 uF output capacitor.

The tones generated are derived from a matrix. Rather than referring to the tone frequencies, the column headings have been designated a, b, c and the rows w, x, y and z (see Table 3). U204 was expressly designed for touchtone format and the circuit board layout is for this particular chip. It is a new

device by Motorola and is designated MC14410. A Microsystems International ME8913 touchtone generator IC was tried at first without much success, due to the rf from the transmitter. If you have experience dealing with this and have some on hand, a board layout is available from the author.

The Motorola chip is a CMOS, digitally compatible, free from rf interference, 16 pin DIP, requiring no special board layouts or bypassing. It requires only one extra part for operation – a 1 MHz crystal cut for 13 pF parallel mode.[1] Full 2 out of 7 or 2 out of 8 decoding is provided on-chip from the internal 1.0 MHz oscillator. With the 0.1% crystal specified, output frequency accuracy is ±0.2%, well within Bell System specifications. Voltage requirements are digitally compatible (+5 volts) and, for our application, the chip features a fast turn on and turn off time, as well as stable operation over wide temperature ranges (−40° to +85°C) for mobile use.

Due to the newness of this chip, some difficulty in obtaining one may be experienced. However, Motorola markets worldwide, and the MC14410 will be available from commercial vendors, and later even as surplus, at reasonable rates. The approximate price will be in the $10 to $15 range in single lots. This IC will not need bypassing or ferrite beads around the frequency pins as is required on the Microsystems chip.

The keyboard in the prototype is an EFS-21289 Chromerics[2]. Other Chromerics keyboards may be used if desired, but since the "feel factor" is miserable, a GTE Automatic Electric PK10 or PK11 keyboard, which is identical to the Western Electric pads, will be used on my next model. Any keyboard may be used, as long as it is wired to produce a valid tone. The 2 out of 7 contact arrangements in the keyboards used above are connected directly to the gate outputs or the frequency determining pins of U204. Any other type may easily be used. If one set of contacts closes at a time, for each number, an SPST arrangement is suitable with one side of all the switches grounded and the other side wired to each input.

An old, non-working WE or GTE pad may also be used if the oscillators have sustained damage. The switching arrangement is similar to the Chromerics one, in that two out of seven contacts close at one time. Damaged pads may be easily and inexpensively obtained at hamfests.

The power supply consists of a 4 mH indicator and capacitor to filter out alternator whine and other trash from the vehicle battery line, and two Fairchild 7805, LM340K or other 5 volt regulators capable of handling a total of 220 mA. These two regulated outputs, A and B, are wired to

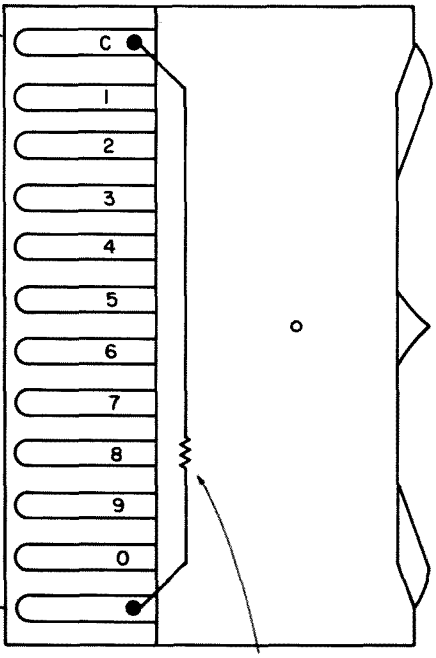

Fig. 9. Thumbwheel switch detail (side view showing method of wiring).

[1] Crystals made especially for this Motorola chip may be obtained from Manann Labs, 425 Main Street, Belton MO 64012 (816-331-5931), for $4.50 each in single quantities, or $2.20 each in lots of 6 and up. Order number ML18P, or ML18W (for wire leads).

Table 2. Truth table, number counter board. An asterisk (*) indicates outputs used; others are not wired.

each board as indicated in Fig. 6. Two are used because 1 regulator with a small heat sink ran too hot to touch. The power supply board also contains relay K1, which provides switching for the audio circuits to two radios and a switched ground for the PTT lines.

The manual keying circuit for use with the keyboard is shown in Fig. 3. Each pin of the keyboard is connected, as per Fig. 8, directly to U204. The COR circuit is driven by pin 7 of U204. Negative going (logic 0) pulses occur when any tone is being generated, and are sensed by Q203, which is usually biased on by the normally high output of pin 7. As the logic 0 pulses reach Q203, it turns off and the base of Q204 then rises to the voltage determined by R210, D201 and R211. Q204 then turns on, thereby providing a switched ground for the internal PTT line. When the tone stops, if the delay switch is closed, capacitor C204 discharges through R211 into the base of Q204 to provide an approximate one second delay.

The prototype unit was mounted in a custom made plastic box. The plastic was bent with a strip heater to conform to a space in my automobile. The corners were sanded and buffed to present a smooth molded appearance. Grey smoked plastic was used in the prototype because it was intended to backlight the panel (through Scotchcal plastic photographic material) to indicate the functions. However, space inside the housing precluded the use of bulbs in the required areas, so photosensitive Scotchcal aluminum panel material was used instead. Any suitable enclosure will be sufficient as long as there is adequate front panel space for the brand of thumbwheel switches used and the keyboard.

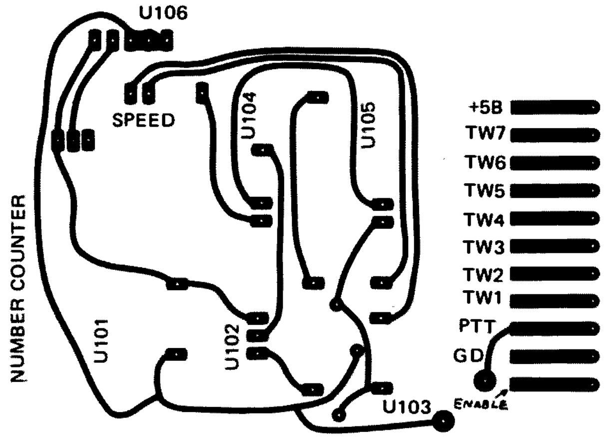

Fig. 10. Top view, number counter PC board (full size).

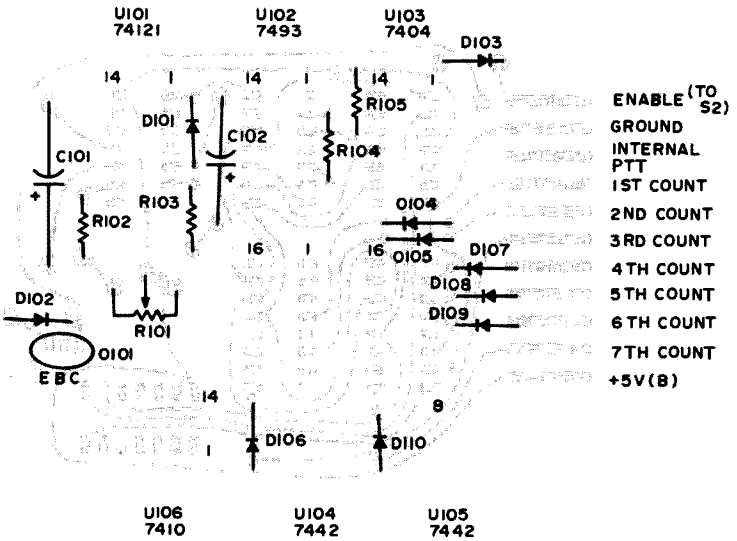

Fig. 11. Bottom view, number counter PC board (full size).

The thumbwheel switch bank consists of 7 thumbwheel switches designed to provide a decimal output rather than BCD. Any 10 position (or 12 position to include the # and *) rotary switches can be used instead, if they are available. Thumbwheels provide a better appearance and the use of a spacer between the 3rd and 4th digits will provide better readability of the full telephone number. The individual numbers 1-10 on each switch are all jumpered together and are wired to inputs 1-10 on the tone and encoder board. Each common terminal of the switches goes to the outputs of the number board: the 1st switch connected to the 1st count, the second to the 2nd count, etc. On most switches, a separate uncommitted terminal is available. These are all connected together and a 10k resistor (R106-R112) attached from this common bus to the common terminal of each switch. The common bus line is then connected to the +5 volt "A" source (see Fig. 9).

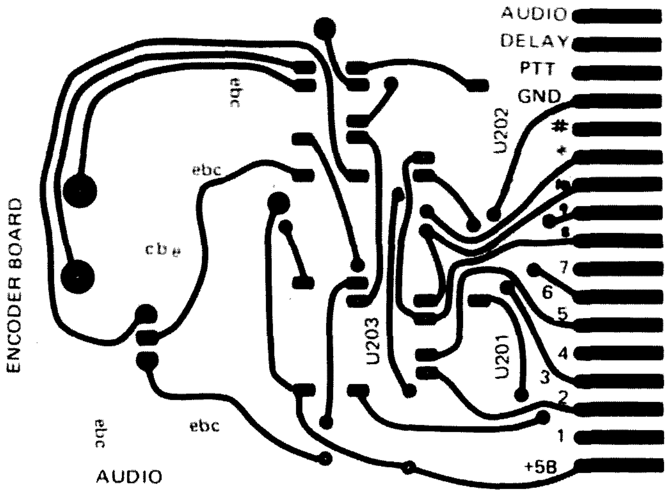

Fig. 12. Top view, encoder PC board (full size).

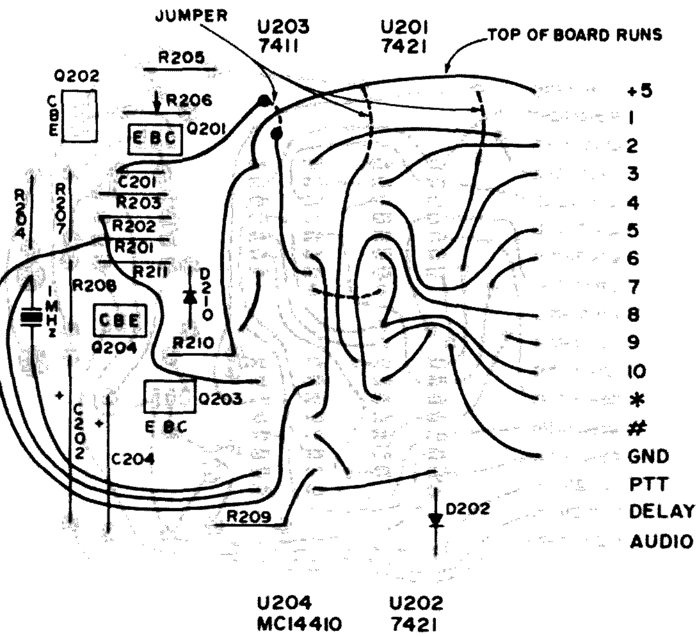

Fig. 13. Bottom view, encoder PC board (full size).

The four boards are plugged into mating board edge connectors mounted inside the cabinet. All wiring is kept as short as possible to maintain neatness, but lead length is not critical. If it is desired, the connectors may be omitted and the boards wired together at the connector foil, making sure that both sides are soldered. A Waldom connector containing 12 pins in a rectangular configuration was used on my enclosure to interface with two radios through a wired-in mating harness. Although the schematics (Figs. 4 and 6) show my hookup, the builder may want to use his own method of microphone and PTT interfacing to his own particular rig. One popular way is to place a microphone connector on the enclosure and plug the mike into it, then make a harness with a suitable plug to attach to the radio mike input. The power supply board containing the audio switching may then be omitted and the 4 mH choke (L301) mounted to the cabinet. The internal push-to-talk line from each board may be used to key the transmitter and the microphone wired in parallel with the encoder audio.

After constructing each board, it would be wise to check the operation before continuing on. The code access and number counter boards are simply hooked to +5 volts and the enable line grounded momentarily. Increased current pulses will be seen on power supplies equipped with milliammeters. The outputs K, L, M and N on the code board and TW1 through TW7 on the number counter board should pulse in sequence on every other clock pulse. A good indicator is an LED tied between each output and +5 volts, with a 220 Ohm resistor in series with each. They should flash in the proper sequence. The speed is adjusted by the pot on each board. Difficulties in performance will be traced to open runs or poor solder joints. Make sure both sides of each board are soldered. The connector pins on each board should be jumpered through the board for added reliability. It was found that the PC board connectors had to be gold plated as the tin plate aged and made poor contact with the edge connector.

The tone and encoder board may be checked by hooking a small audio amplifier to the audio output, +5 volts and ground to the proper terminals, and grounding each input in turn. The tones should be fully adjustable with the level set adjustment. If

difficulty is experienced, short one each of the a, b, c and w, x, y, z pins of U204 to ground to insure that the chip is operating. Then work backward to each gate, placing a ground on the input and checking that the output goes low.

If all seems to be working, wire the printed circuit card connectors together following the overall schematic in Fig. 6. In this case, wire wrap is very helpful if you have the capability. However, use of small #22 or #24 wires will aid in ease of wiring. #20 or #22 should be used in the external cable for better handling. The edge connectors can be a cinch 50-10-A-20, 2 cinch 50-12-A-20 and a 50-18-A-20 or their equivalents.

Again it is better to check the progress as you go along rather than find you made a wiring error later. Do the power supply connector first, wiring all internal connections and the external cable harness. Then wire the tone and encoder board connector to the power supply. Check operation at this point by applying +12 volts to the external input plug and generating a tone to see if relay K1 closes. Grounding the wire from the "delay" pin on the encoder board will cause the relay to release approximately 1 second after the tone stops. If all seems normal, proceed with the code and number counter boards. Grounding either enable input on these should generate the proper tones. The K, L, M and N outputs should be wired (in that sequence) to the tone board inputs corresponding to your repeater access code. If you only use 2 or 3 tones for access, use the first 2 or 3 letters of the sequence, because the K output stays on twice as long as the others (e.g., two clock pulses).

Next, wire the front panel controls. If the Chromerics pad is used, it should be mounted very carefully, making sure there is an easy fit between the 4 plastic shoulders. Warping this pad in the installation may make one or more contacts close, thereby keying the push-to-talk continuously.

If you elect to use an LED indicator over each thumbwheel switch so the scan sequence can be seen, wire these in next. The prototype had this feature but on later versions they were omitted for being redundant. Operation is heard with the internal audio amplifier, and the push-to-talk line indicator LED shows the sequence just as well. If they are used, attach a 270 Ohm resistor to each LED. The other end of the resistor goes to the 5 volt bus line on the switches and the anode of the LED connects to the common terminal on each switch (see Fig. 9).

Check for shorts in the wiring and then

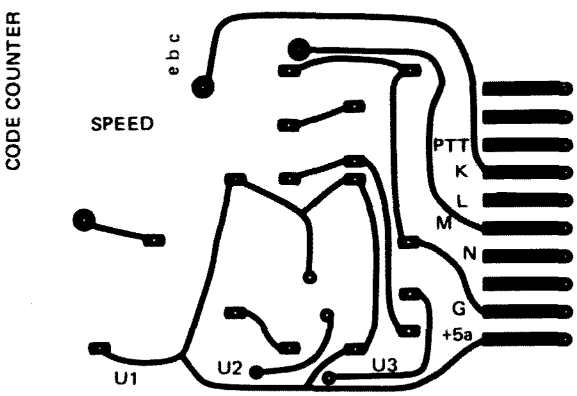

Fig. 14. Top view, code counter PC board (full size).

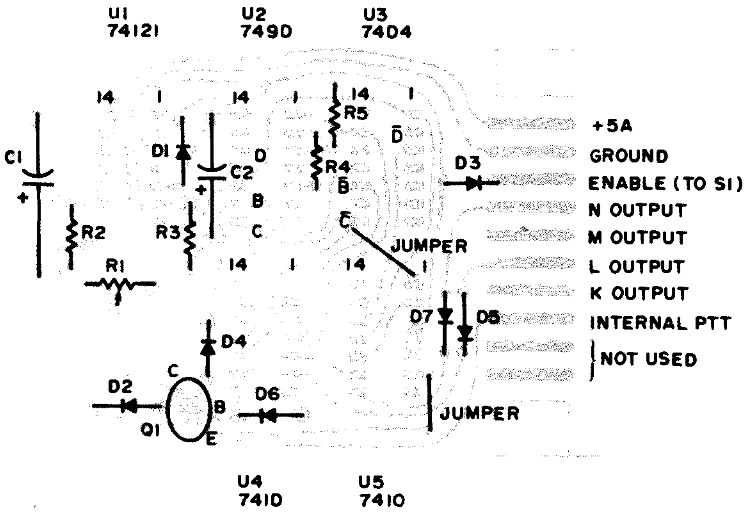

Fig. 15. Bottom view, code counter PC board (full size).

apply 12 volts, and check the overall operation. With the delay switch off, push each number on the keyboard and insure that the PTT LED lights and the relay closes. With the delay switch on, a delay of approximately one second will exist before the relay opens. Push the access code push-button (S1). The PTT LED should light, and if any of the numbers in the code correspond to what is in the thumbwheel switch bank, those LEDs above their respective switches should light. When the PTT light goes out, sequence the Number button. Again, each LED above the thumbwheel switches as well as the PTT LED should light, the former in sequence from left to right and the latter as long as the cycle is going. If all seems well, wire it into the transceiver. Do not close the box yet.

To set it up, have a friend listen to your audio and set the level adjust on the tone and encoder board to what he hears as just slightly lower than your voice. (Individual repeaters have different requirements but this should be a good way to "ballpark" set

		U14 Pin 4 1209 Hz (a)	U14 Pin 5 1336 Hz (b)	U14 Pin 6 1477 Hz (c)

Table 3. Touchtone matrix showing coding from U15 to U14.

it.) Punch in the access code, both automatically and manually, to check for wiring errors. The automatic code access board speed should be adjusted to just under what is too fast to bring the dial tone up. Next try to dial a number. Again, use both the keyboard and then the automatic feature to check operation. Too fast a dial rate will not be accepted by the telephone company equipment. Too slow a one may result in false dialing when you have a weak signal into the repeater. Ideally, for an exchange with all electronic switching, a speed of 40 ms on and 40 ms off is as fast as you can dial. Some older non-electronic exchanges won't go that fast. The best way is to experiment, leaving the dial rate adjusted just slightly slower than the fastest speed you can dial.

If you have trouble accessing the dial tone or getting the number to ring, be sure your transmitter is on frequency and your deviation is properly set, as well as mike gain (if provided) in your transceiver. Clipping, distortion, noise and otherwise low quality tones will almost never work.

The unit has been in use for about 13 months and has been tested to extremes of temperature, from the bare circuit boards lying on the floor under a 195° F heater, to start-up in the morning when the ambient temperature has been 15° F. With proper components (i.e., tantalum capacitors in the audio coupling and timing circuits), no thermal problems should be experienced. Re-design of the tone encoder using the Motorola MC14410 resulted in extremely reliable operation. The only problems experienced were with the ME8913 Microsystems International generator, which required extensive bypassing and ferrite beads around the frequency determining pins.

One word of caution to repeater groups is in order. It would be easy to manually dial a number like 1-703, then let the logic transmit seven digits very quickly. Since the phone company will allow the 40 ms dialing rate, other listeners may not realize a long distance call has just been placed. Number counters should be standard equipment on all repeaters.

The unit is a pleasure to use and sounds quite professional, just like the tones one sometimes hears on intercity or long distance dialing. It has also functioned as a conversation piece, for every time it has been used someone invariably has wanted to know how I learned to let my fingers walk so fast through a touchtone pad. ■

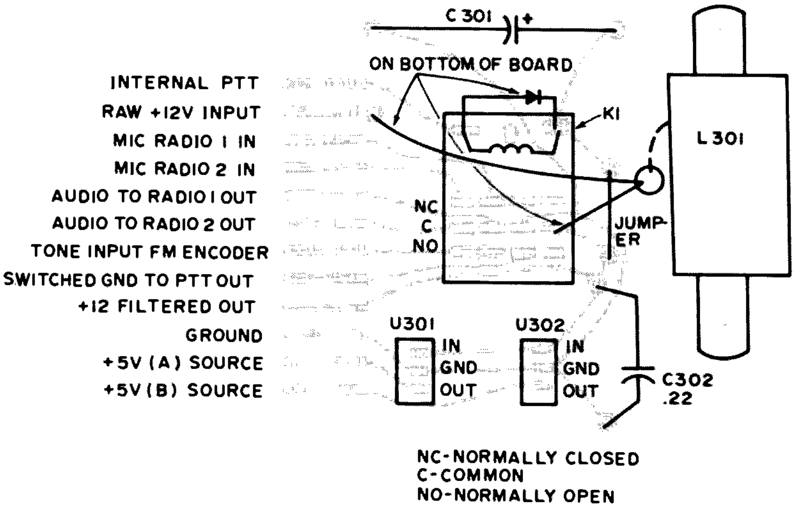

Fig. 16. Power supply PC board (full size).

Zapping Dead Nicads

by
Peter A. Stark K2OAW
196 Forest Drive
Mt. Kisco NY 10549

A major cause of nicad failure is overheating, caused usually by excessive charge or discharge . . .

Though individual nicad cells are relatively inexpensive, complete nicad batteries for specific pieces of equipment often cost an arm and a leg. The 15 volt batteries for 2 meter walkie-talkies are a typical example — they often cost $30 to $60 and up, depending on the source. Anything that can be done to lengthen their life is therefore of great interest.

This article is a continuation of an earlier article I wrote in the December 1974 issue of *73 Magazine*. As a result of that article I have received several letters from readers which have spurred me on to further reading and experimenting. This has led to several techniques for repairing or reconditioning nicad batteries, which should be of help to many nicad users.

In the 1974 article I mentioned that a major cause of nicad failure is overheating, caused usually by excessive charge or discharge. The big problem is overcharging the battery. The resulting heat causes a pressure buildup, which in turn causes venting of the sealed cell through the safety vent. This vent acts like a safety valve to relieve internal pressure and prevent a possible explosion. I had indicated that an occasional slight loss of electrolyte through venting would not cause too much harm, as the safety vent would reseal itself after the venting.

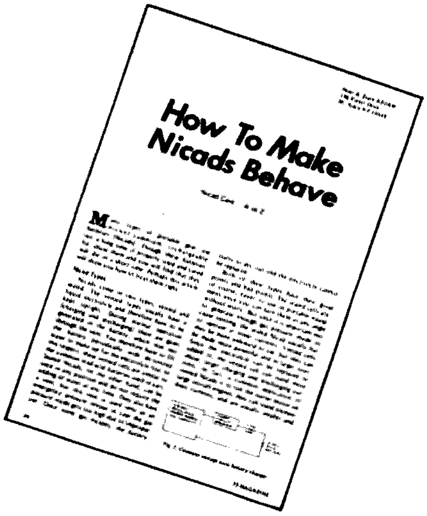
One reader (Lloyd W. Root K7AS) wrote to say that he has had much experience with nicads over many years, and has done a number of experiments on them. One of the things he has found is that some of the nicad safety vents are not resealable. They can be identified by a triangular hole in the positive end of the cell. The small metal tab stamped out of this triangular hole is aimed inward like a sharp point; under this tab is a thin plastic membrane which seals the cell. In case of internal overpressure, the plastic is pushed outward against the sharp point, which punctures a small hole in the plastic to release the pressure. Once this hole is made, it stays there and the cell soon dries up. When this happens, the cell will only hold a charge for a very short time.

Lloyd Root reported having experimented with a number of such dried-out cells. He disassembled one to see how it was put together, and found a place where he could drill a tiny hole through the case without shorting the internal plates. Then he injected distilled water through the hole with a hypodermic needle. By replacing the missing liquid, he renewed the cell to the point where it performed almost as good as new. Though I have not yet tried it, I suspect that a similar result could have been achieved by immersing the cell in distilled water and then applying pressure to the liquid in some way — perhaps by using a thick rubber bag or hot water bottle and squeezing it — to force the water back into the cell. Were it not for the fact that high temperature is very dangerous with nicads, the use of a pressure cooker would be very tempting! In any case, the vent could then be *loosely* covered with tape to prevent the liquid from evaporating again.

It is very important not to cover the safety vent and thus prevent it from working. I am told that when a nicad explodes from excessive pressure it really makes a mess. This brings to mind a dangerous condition I have seen in several batteries. As soldering to nicads is dangerous, welding is used to attach contacts to cells in multi-cell batteries. These connections are generally made with metal strips rather than wire to allow easier welding. In several instances I have seen the metal strip welded directly *over* the safety vent, thereby creating a safety hazard.

I have found that electrolyte leakage can

to Life



How To Make Nicads Behave

cause another safety hazard which may, under some conditions, lead to damage to the battery, charger, or walkie-talkie, and possibly even an explosion. This applies particularly to rapid-charge batteries. Here's why: The electrolyte which leaks out of a nicad is not just pure water, but actually is a conductive chemical. If a cell in a sealed battery such as the 15 volt battery for a 2 meter Motorola walkie-talkie leaks, the electrolyte forms internal leakage paths inside the battery which can discharge cells and form internal high resistance shorts.

Those nicad batteries designed for rapid-charge use have a built-in thermistor connected to an external contact on the battery, which allows the charger to sense internal temperature. As long as the battery is still partially discharged, cell temperature is fairly low and the thermistor resistance is also low. As soon as the battery is fully charged, cell pressure and temperature start to rise. This makes the thermistor resistance go up to 1k and more. This signals the charger to switch from its high-current charge rate (which is designed to charge the nicad in one hour) to the standard low-current charge rate.

Now suppose that electrolyte leakage inside the battery puts a high-resistance short across the *thermistor.* Even though the battery is fully charged and the temperature is rapidly rising, the charger still sees a low resistance and therefore continues charging at the high rate. This can rapidly melt all the plastic parts on both the battery and charger, and in an extreme case even cause an explosion.

Short of periodically opening the battery to look for leakage (and rinsing it out with water if you find any), there is no foolproof way of detecting this problem before it causes damage. But there is a simple test which may sometimes spot the problem before it becomes serious. This is to connect a voltmeter across the thermistor contacts on the outside of the battery. You should not measure *any* voltage. If you do, then there must be some internal leakage path between the thermistor and at least one of the cells, indicating that some electrolyte has been vented.

Another common cause of nicad failure is internal shorting of one or more cells. In a single cell you can identify this problem by the fact that the cell measures exactly 0 volts, and when checked with an ohmmeter measures 0 Ohms. In a multi-cell battery you may note that the open-circuit voltage of the battery is less than the usual voltage even after a full charge. A normal nicad cell measuring 1.25 volts under most conditions will reach 1.4 volts or even slightly more during and right after a charge. Thus the 15 volt battery from a Motorola HT-220, which has twelve cells, will read up to about 17 volts right after it is charged. If the open-circuit voltage after a charge is only 15 volts or even less, that indicates that one or more cells are shorted.

I have in the past thrown away a number of shorted cells, and now wish I had kept them. That's because I have found a way to fix them. I presently have four batteries for my HT-220 which were given to me because their voltage was down to as low as 7 volts. I have now been using them for some time to see whether they will fail again. In one of these batteries, which started out with four shorted cells, one of these cells has shorted again, but I was able to again rejuvenate it and it has been working ever since.

The idea came to mind while I was carefully rereading a part of the GE "Nickel-Cadmium Battery Application

Short of periodically opening the battery to look for leakage, there is no foolproof way of detecting this problem before it causes damage . . .

Another common cause of nicad failure is internal shorting of one or more cells . . .

Once a cell is already shorted why can't we burn out the short by applying an external heavy current burst?

Engineering Handbook," Publication No. GET-3148 (and its supplement GET-3148S), available from the General Electric Company, Battery Products Section, Box 114, Gainesville FL 32601. At one point they mention that sudden failure due to internal shorting of a cell is more common when a battery is discharged than when it is fully charged. Though they are not sure of the exact reason, they speculate that this may be because internal shorts start out by being very small needle-like projections which short the two plates together. A well-charged cell may be able to burn out this tiny short as soon as it forms by passing a heavy current through it, whereas a discharged cell can't. Well, I thought, once a cell is already shorted why can't we burn out the short by applying an external heavy current burst? I asked several friends for their old, shorted walkie-talkie batteries and went to work.

The first time I did this I took the time to open the battery case using a knife attachment on my soldering iron and a lot of force. Some battery cases are easier to open than others. The cases for the replacement HT-220 batteries made by Alexander Manufacturing appear only to be glued together at the corners, and easily come apart. The original Motorola batteries, on the other hand, are sonically welded all around, and attached with two studs in the middle as well. Quite a bit of huffing and puffing is required to open them up.

Once open, I borrowed a trick suggested by K7AS. He noted that a cell which has been reverse-charged will not take a charge of the proper polarity unless first given a heavy burst of current from a regular dry cell connected directly in parallel with the nicad. Since a new dry cell has a voltage of about 1.5 volts and a fairly low internal resistance, this pushes a good current through the nicad, forcing it to take on the proper polarity. When the nicad cell reaches 1.5 volts, the current drops to a very low value.

Knowing which cells of my battery were shorted, I took a no. 6 dry cell and very heavy leads and connected it directly across each shorted nicad cell, plus-to-plus, for about five or ten seconds. This gave each shorted cell enough of a current burst to burn out the short, and even gave it a slight charge. After removing the dry cell, I noted that the nicad cell now had a voltage across it. Since this particular battery had four shorted cells, I repeated this procedure once for each cell. Once the shorts had been removed, I put the battery into the charger and charged at the standard rate for 15 hours. I have now been using the battery for several weeks, and it has been performing well. I am, however, careful not to discharge the battery all the way lest one of the cells short again, although tests on other batteries to determine total battery capacity – down to a total discharge – have only once resulted in a shorted cell which was easily repaired.

But opening Motorola batteries is a chore, so the next three batteries were fixed without being opened. The procedure is similar – putting a heavy current through the battery – but the technique of doing it is slightly different.

My first try worked, but not reliably. It consisted of taking a 30,000 uF computer-type electrolytic capacitor, charging it to 25 volts, and then discharging it into the nicad battery. After several tries this did bring one of the shorted cells up to voltage, but it appeared to be a laborious job at best. Obviously more drastic steps were needed.

I, therefore, started by putting the entire battery into the charger and charging at the standard charge rate (.1C) for 15 hours. Though this did nothing for the shorted cells, it did result in the good cells being fully charged. Now I took a pair of pliers and connected the jaws directly across the battery terminals to provide a nice, low-resistance short across the battery for about 2 to 3 seconds. The resulting short-circuit current, provided by the good cells in the battery, burned out the shorts in the shorted cells. It also slightly reverse-charged the bad cells, which I immediately counteracted by putting the battery into a high-current (.5C) charging circuit for about 30 seconds. Then I charged the batteries for several more hours in the standard .1C charger, and checked the open-circuit voltage. In a few cases, the treatment had to be repeated several times to repair all the shorted cells – one of the batteries had 5 cells out of its 12 originally shorted – but eventually the battery voltage came up to 17 volts after a charge, and stayed there.

In addition to the reference given earlier to the GE nicad manual, other prominent nicad manufacturers include Gould, Eveready and Union Carbide, who may be able to supply additional information if you need it. There is also a booklet available from the U.S. Government, which I have requested but not yet obtained; it is a report entitled "Chargers and Charging Techniques," no. LESP-RPT-0202.00, which applies specifically to nicads used in portable radio gear. It is available from the National Criminal Justice Reference Service, Law Enforcement Assistance Administration, U.S. Department of Justice, Washington DC 20530. ■

Plugboard Extender for Under $3.00

by
Kent A. Mitchell W3WTO
1004 Mulberry Avenue
Hagerstown MD 21740

Recently, I had the opportunity to purchase some surplus digital equipment. One such unit, a specialized shift register type used to test some NASA space hardware, contained approximately 50 plug-in circuit boards on which were mounted hundreds of transistors and other components. This unit, once an example of state-of-the-art construction, is now 10 years old and in these days of integrated circuits is in style about as much as a '53 Studebaker. So, I was able to acquire the gear for only $5.

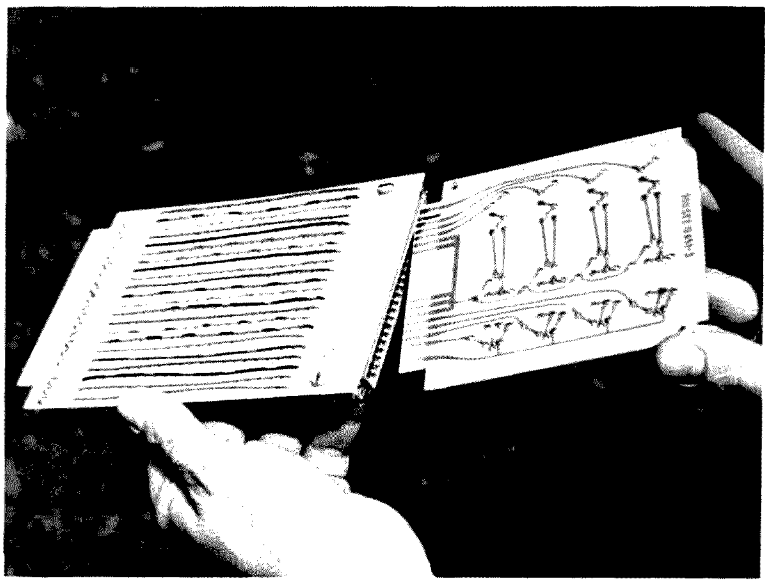
However, before I even thought of cannibalism, I could not resist firing up the equipment to see what would happen. (The unit contained a husky 5 volt power supply – alone worth the price.) Immediately, lights lit and registers shifted. Well now, after second thought, why not experiment a little bit and see if I couldn't build my own not-so-miniaturized calculator?

First problem was how to get 'scope probes on some test points to find clock pulses, etc. The circuit boards themselves are coated with a thick layer of glop called MFP (short for moisture-fungus-proofing) so direct contact with component leads was not possible. The board sockets would be the next logical place for signal access; however, these were recessed deep within the chassis and covered by wire bundles. Clearly, what I needed was a "board extender," that is, a simple point-to-point wired plug and socket arrangement which would enable the selected circuit board to be connected into the chassis circuit while being physically external of the chassis.

A quick glance at my selection of parts catalogs shocked me into the realization that such a simple item was priced at a minimum of $15. This was three times what I had paid for the unit I wanted to test. There had to be a better way – like build my own. Back to the catalogs!

Vector Electronics Co. produces a "Universal Plugbord" series that are blank except for the etched contact fingers and prepunched with a grid of holes for experimental component placement. A 22-contact board of this type is available inexpensively from Burstein-Applebee Co., 3199 Mercier St., Kansas City, Mo. 64111.

Next, an appropriate socket needs to be bolted onto the board, and these are usually available from Poly Paks Inc., P.O. Box 942, South Lynnfield, Mass. 01940. Some scraps of hookup wire connect the two and a handy test aid is added to the shack. ■



Eyes For Your Shack

Conclusion

by
G. E. Friton WØACR
628 Marshall Ave.
Webster Groves MO 63119

The moment of truth (or consequences) has arrived! Install all active components *except* Q303, 4, 5, 7, 8 and 9 in the vertical amp, and Q405, 6, 8 and 9 in the horizontal amp. Set your scope's controls: intensity, three quarters CW; focus, midrange; astigmatism, midrange. The remaining controls will get set as you progress with initial checkout.

Again, remember that those innocent-looking batteries can easily reduce your scope to a pathetic pile of rubble in 2 seconds or so, should a minor disagreement in who is going to control things develop (it will). So use a 1 Amp fuse in series (it'll never blow, of course), to discourage such outbursts of temper.

Apply power. Note that both inverters start (it won't exactly sound like the Boston Pops, but it'll sure sound good!). Check +5, −5; set +95, positive and negative HV (the latter two depend on the options chosen). By this time, there should be a bright, unfocused spot on the CRT. Set the intensity control for a medium brilliance spot, and check the focus control. Since the astigmatism control has not yet been set, the focus probably won't be too sharp. Reduce spot intensity to dim, and remove power.

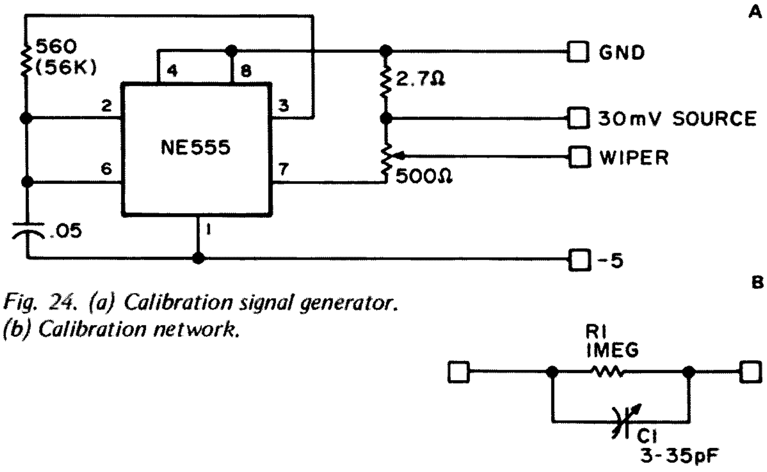


Fig. 24. (a) Calibration signal generator. (b) Calibration network.

Horizontal Board Setup

Install Q405, 6, 8 and 9 in the horizontal board. Set the scope's controls: timebase, 1 ms/div; mode, ac; level, CW; slope, +; horizontal position, midrange; variable controls, Cal.

Apply power. Adjust horizontal position control to give 42 V on the collector of Q405. Then adjust R438 for 42 V on Q408's collector. Beam should now be in the center of the screen. Check operation of horizontal position control – should move the beam from right center to off-screen left.

Set mode to AUTO, timebase to 100 ms/div, and center the trace. Note direction of the sweep; if it's backwards, reverse the connections to the CRT horizontal plates. Set timebase to 1 ms/div. Adjust R422 for a horizontal trace fully across CRT. This completes initial setup of the sweep board. Turn the scope off.

Vertical Board Setup

Next to be adjusted is the vertical deflection amplifier. Insert Q303, 4, 5, 7, 8 and 9 into their respective sockets in the vertical amp. Set scope controls: vertical position, midrange; vertical input, GND; vertical attenuator, 1 V/div; timebase, 5 ms/div; trigger, INT. Turn the scope on. Set R320 on the vertical amp board to give 42 V on Q309's collector. Set R318 for 42 V on Q305's collector. Check that the vertical position control causes the trace to deflect off-screen up and down. Using a flashlight cell, note that trace deflects up for positive vertical input; if not, reverse vertical plate leads. Switch vertical input to ac, and apply your .001% accurate 60 Hz source (finger) to the vertical input. Note wiggly line on CRT. This checks out the basic operation of the vertical amplifier board.

CALIBRATION

Now what is needed is a cheap and simple semi-square wave source, of reasonable risetime. If you have a function generator handy, fine; otherwise, throw together a simple one from a 555. Fig. 24(a) gives the circuit, with 40 ns RT, sufficient for our purposes. The pinouts are correct, backwards as the circuit may seem. Connect test oscillator to −5 V source (scope's −5 is OK). Connect test oscillator's 30 mV output to vertical in. Set vertical attenuator to 10 mV/div, trigger mode ac HF, and timebase to 50 us/div. Adjust trigger level for stable trace; then readjust timebase for 1 to 2 cycles display. Disregarding any overshoot, set R310 (vertical board) to give approximately 3 divisions deflection.

There are two trimmers on the vertical amp board. Initially set each one to minimum capacity position. Then, observing the rising and falling edges of the waveform, adjust each trimmer equally to achieve the best looking edges with minimal overshoot and ringing. Slightly rock each trimmer individually for final tweaking.

Remove the generator, and modify it for 1 kHz, by increasing the 560 Ohm resistor to 56k. Set the generator's pot for minimum output, and reconnect to your scope, using the wiper for vertical input.

Reapply power, and set the scope for dc coupling, ac LF, 5 ms/div. Adjust the level control, if necessary, for a stable presentation of several cycles. Carefully set the astigmatism pot R601, and focus control for best focus in the areas indicated in Fig. 25(b). You will need to alternately adjust each control several times for best focus.

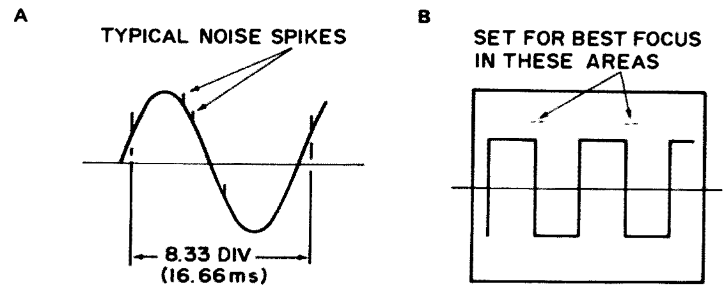

Fig. 25. (a) Timebase calibration. (b) Astigmatism set.

Vertical Attenuator Compensation

Now for vertical attenuator compensation. You'll need the little network, Fig. 24(b). Follow the procedure of the calibration chart carefully. Always set the generator for 3 to 4 divisions display during this procedure.

Following the compensation procedure, you'll need to fine-adjust the vertical gain pot; use a fresh D cell as vertical input, negative grounded. Set the scope for .5 V/div and, with input grounded, set vertical position for a trace on lowest line of graticule. Switch to dc coupling, and adjust R310 for very slightly over 3 divisions deflection. All other ranges are now calibrated.

Only one thing left to calibrate – the timebase. A reasonable job may be done with your calibrated finger, by setting the oscilloscope for 2 ms/div, in AUTO mode.

Vertical Attenuator Calibration Procedure

Vertical Attenuator (V/div)	Generator Output	Adjust	Result (Set for best square wave)
.01	network	C1	Adjusts network to vertical amplifier input capacity.
.02	direct	C714	Adjusts x2 attenuator.
.05	direct	C711	Adjusts x5 attenuator.
.02	network	C713	Adjusts x2 input capacity.
.05	network	C710	Adjusts x5 input capacity.
0.1	direct	C708	Adjusts x10 attenuator.
1.	direct	C705	Adjusts x100 attenuator.
10	direct	C703	Adjusts x1000 attenuator.
0.1	network	C707	Adjusts x10 input capacity.
1	network	C704	Adjusts x100 input capacity.
10	network	C702	Adjusts x1000 input capacity.

Applying your finger to the vertical input will give about 1 cycle of 60 Hz, usually with in-sync pulse-type garbage riding along (fluorescent or dimmer transients). With the horizontal position control, set one of these spikes on the leftmost line of the graticule. Then set R418 to place the next identically-placed spike slightly less than 8½ divisions from the first as shown in Fig. 25(a) – 8.33 divisions to be exact.

To be a bit more exact in timebase calibration, use that handy signal generator in the living room. Simply place the vertical probe near the TV. By locking on field rate, 60 Hz, you have accurate 16.6 ms markers, the vertical sync pulses; and using ac HF coupling, you can lock onto 15,750 Hz (horizontal sync), to check the timebase with 63.5 us markers. To check the highest sweep speed, locate the 3.58 MHz oscillator (if the XYL will let you dig into the set), and drape the probe near it. On 1 us/div, you should have 3½ complete cycles per division. Since part of the timing capacitor is cable capacity, an unknown, wait until everything works, and is neatly cabled, before making any value changes to tweak the 5, 2 and 1 us/div ranges in. Normal cabling length (6" or so) will affect it 10 – 20%.

Congratulations! You now have an indecent oscilloscope! Of course it's indecent – you haven't dressed it up yet!

Professional Touches

Some thoughts on making a really professional front panel . . . remember that template of the front panel? Now's when it'll prove invaluable. Make a few copies of it with carbon paper and use one of these to pencil in the nomenclature in approximate position. Then make a very careful, squared-off version for a lettering guide.

You now have two choices: Either do the finished lettering, actual size, on a piece of lightly frosted mylar, and use by sandwiching it between clear or colored .020 acetate or polycarbonate and white paper, or make a double size version, get an actual size negative, and contact print one on standard black and white photographic paper. Then sandwich this photo between the front panel and acetate. The latter method will generally give a more finished appearance. Note that plexiglas is unsuitable as a cover material, as it will crack under the uneven strain of pulling down mounting nuts, where polycarbonate and acetate simply give a little.

The Charger and Ac Power Supply

Another needed item is an ac power supply – charger for your scope. Fig. 26 is a power supply that will support the scope indefinitely, or fully charge the Gates batteries in about 5 hours, nicads overnight. Use the appropriate network and set the regulator correctly for the type of batteries you have.

Note the use of a non-shortable polarized charging plug, and the diode D601 to prevent backfeed shorts. This diode has proven very handy at times; if you forget the charger, simply use a 150 W lamp (Gates cells) or a 40 W lamp (2A-H nicads) for a charger.

Cleaning It Up

With everything working, it's now time to nitpick a bit. Check to see if inverter garbage is getting into anything; it'll probably show up as small pulses on the trace, or erratic sync problems. Suspect grounding or lead dress problems first. Check by strapping a suspected ground to different points, and moving leads and cables around.

When you're satisfied with your scope's performance, tiewrap the cables neatly. Remember, you may need to touch up the 5, 2 and 1 us/div sweep speeds. Put the cover on, charge the batteries fully and enjoy.

Accessories

First thing you'll want is a good 10x probe, easily carved out of a gutless ballpoint pen. File a small nail into a probe, solder a paralleled 9.1 meg, and 2-20 pF trimmer to the nail head, and add some RG 174 U. Adjust using a square wave.

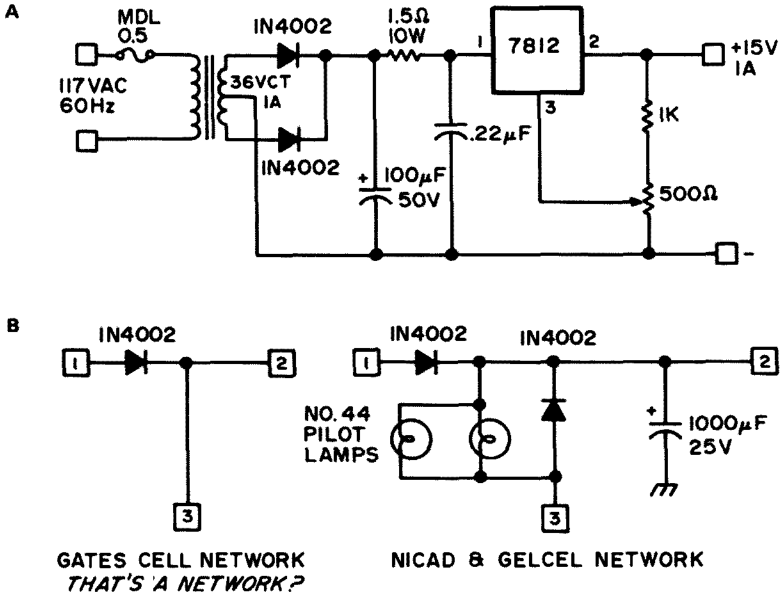

Fig. 26. (a) Power supply – charger. 7812 must be well heat sinked. Set output for 14.7 to 15 V for optimum battery cycle life. 15.6 V will materially shorten life of Gates cells. (b) Charge networks.

Another extra is an illuminated graticule – all that needs to be done is mount a couple of miniature lamps on the plexiglas graticule edge. The scribed lines will glow brightly. A push-for-illumination switch will conserve the batteries.

Also, a handle should be added to your case for carrying ease. A swivel type, mounted somewhat forward of center, will double as a tilt stand.

Hindsight

Typical of such a project, looking back always finds things that can be improved. A few things you might consider for your scope:

1) A x10 expand for the timebase. This is relatively easy to implement: Change R429 to 1.2 meg, and make R422 switch-selectable 10k and 100k pots. Effective top sweep speed will then be 100 us/div. By the way, the 555 gets downright ornery if you try to push it that far, so don't expect it to go much past .5 us/div . . . use the expanded-sweep method instead.

2) A simple but handy addition is switching of the auto mode coupling capacitor (C606) to keep the trace bright at high sweep speeds with no input. Use 1 uF, 0.1 uF, and .01 uF, the latter value to be used with the high sweep speeds.

3) A somewhat better regulation scheme for the HVPS, involving direct tapoff of the negative high voltage, instead of at the first multiplier. This was used in an earlier supply, and is capable of much better regulation, but is more expensive, due to the greater number of zeners required.

4) Dual trace capability: The vertical amplifier is designed to accept this inclusion with minimal changes. Make another vertical preamp, up to Q302 and Q306. Then use an astable multivibrator to drive FET or 4016 CMOS switches placed in series with Q302 and Q306 signal lines, switching between each preamp output. Also include a summing point for all the blanking signals, and trigger pickoff for alternate trace generation.

5) A protective cover, if you intend to use the scope in the field. Such a cover, of vinyl or cloth, can probably be made by the YL or XYL (for the price of a little flattery).

A Wee History

Begun from scattered ideas in May '74, and completed in September, the scope has since been in constant use and has proven to be extremely useful, stable and rugged. It has been used in 5° weather, kicked, rained upon, and worst of all, subjected to travel in my Jeep. It's a hardy little devil! ■

It's been used in 5° weather, kicked, rained upon, and worst of all, subjected to travel in my Jeep. It's a hardy little devil!

Build This Digital Capacity Meter

by
I. M. Chladek
PO Box 93
Kenmare
1745
Rep. of South Africa

One of the common problems any constructor faces is determining the exact capacity of a capacitor from his junk box or for use in af filters, etc. Small (and cheap) RLC bridges are not accurate enough and – if, for example, you try to measure 100 mixed values of capacitors from a surplus pack – you may well run out of patience. Furthermore, in the age of integrated circuits and frequency counters, everybody is getting lazy. Well, here is an instrument which eliminates all these troubles, presents the value of capacity instantly in digital form, is highly accurate and is fairly simple to construct.

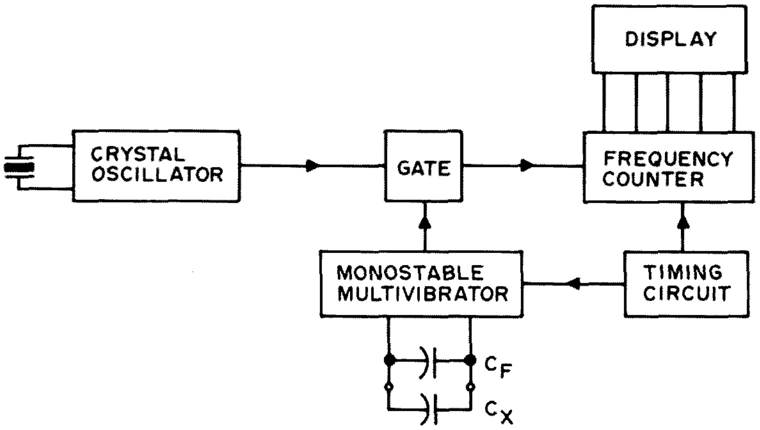

Fig. 1. Block diagram.

First, some information about the C-meter:

1) It measures capacitors from 1 pF to 1 uF in two ranges – 9999 pF and 999.9 nF.

2) Display is four digits in the above ranges, with leading zero suppression and overflow indicator.

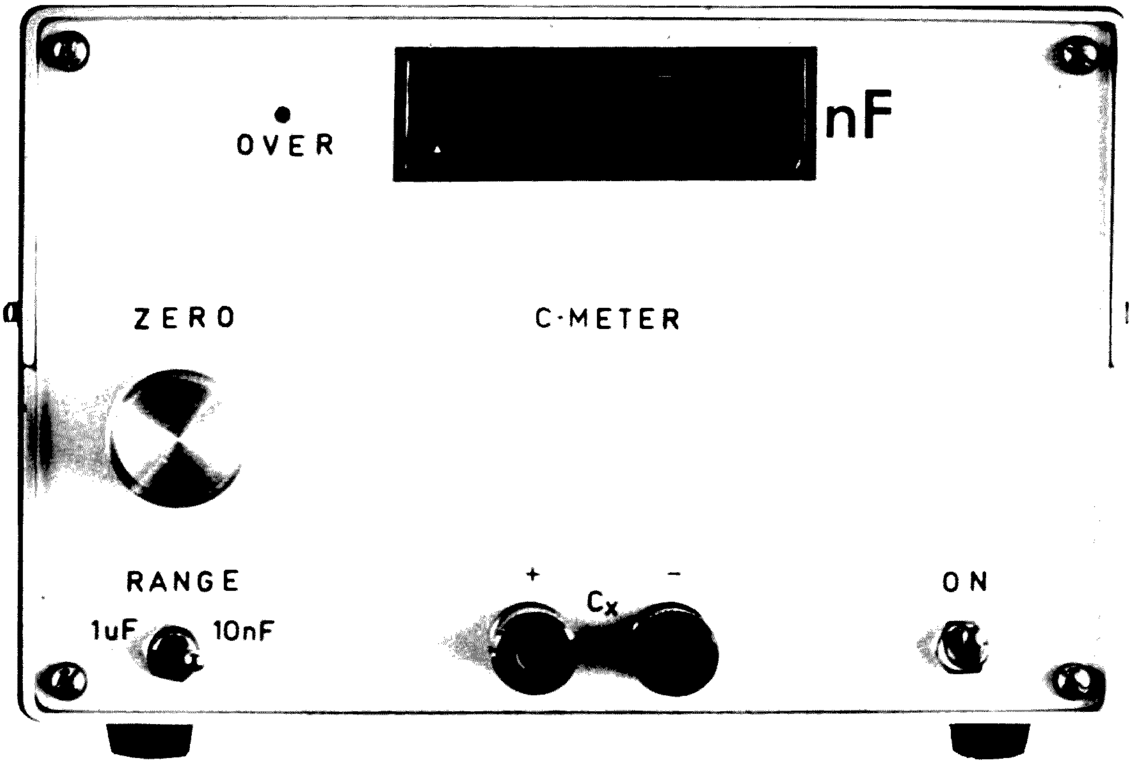
3) Accuracy is better than ± 0.1% of full range ± 1 digit for higher values of capacitance in both ranges; for lower values of capacitance it is still very good (i.e., it is possible to determine if the measured capacity is 1 or 2 pF). (The above accuracy is of course in relation to the standard used for calibration of the C-meter and applies only for capacitors with a good Q – see text.)

4) No warm-up period is required. It measures immediately after switching on, with full accuracy.

5) Operation is extremely simple, with only two controls: zero adjustment and range switch.

6) With the exception of a power supply, the whole unit fits on two small printed circuit boards.

7) The price of the complete unit should be around $50, depending on how familiar



you are with cheap sources of TTL integrated circuits. (Maybe most of them are in your junk box.)

The basic principle is very simple and well known; the only difference is *how* it has been used. A similar unit was described some time ago, but it measured only higher values of capacitance, and used different devices.

Fig. 1 shows the block diagram of the C-meter. The heart of the unit is the monostable multi-vibrator (MMV), which produces gating pulses. The length of these pulses is directly proportional to the value of capacitor C_X. I had to consider practical limits of the MMV integrated circuit used (SN74121), the crystal oscillator and the frequency counter described later. Using only C_X and no C_F, with the highest permissible value of the timing resistor, will result in a pulse length of about 25 usec (see data book for SN74121). The crystal oscillator frequency must then be 40 MHz in order to obtain "1000" on the display. But, due to the long leads to the terminals for C_X, hum, etc., the display was not stable – especially for values of C_X under 100 pF. To be on the safe side, I decided to start with a value for C_F of 1000 pF. This cured the problem. But with no C_X on the terminals there was "1000" on the display. Well, instead of resetting to "0000", I reset the counter to "9000"; then with no C_X it counted to "10000", but the first digit was not displayed and the resultant display was "0000". Similarly, for higher range, the counter was reset to "9990". Reset circuits are then a bit more complicated and the overflow indicator must be a two stage counter, but this is not a serious complication.

Capacitance ratio between range 1 and 2 is 1:100. To obtain a correct reading on range 2, the frequency of 40 MHz (for range 1) must be divided by 100, resulting in a frequency of 400 kHz.

The last part of the C-meter is the timing circuit. It generates trigger pulses for the MMV, strobe pulses for latches and reset pulses for counters. The last ones are distributed as described above with the help of a few TTL gates.

Flicking of the least significant digit is not suppressed for two reasons: to simplify construction and to enable recognition of differences between, say, 17.0 and 17.5 pF. In the latter case, the display would have changed from 17 to 18. I used cheap Minitrons for display and this determined the frequency of the timing circuit; it must be low enough to read both values comfortably, e.g., 17 and 18. After a few tests I left it at about 2 Hz. The timing oscillator is then running at 20 Hz and is divided by 10 with the SN7490. Pulse "4" is used for

The basic principle is very simple and well known; the only difference is *how* it has been used . . .

triggering the MMV, "6" is used as strobe pulse for latches, and "8" is used for reset pulses. This system works very well, and leaves about 100 ms between trigger and strobe. With 1 uF and 40k Ohm, the SN74121 generates about 25 ms pulses, so that it is well within the above 100 ms. Any other combination of the outputs from the SN7490 is, of course, possible.

I decided (after some consideration) to divide the instrument into two parts:

1) Crystal oscillator, MMV, timing circuits and gate.

2) Frequency counter and display with overflow indicator.

Both parts can be tested separately before final assembly of the C-meter . . .

This arrangement reduces the size of the printed circuit boards which are mounted in parallel and interconnected by means of a few wires. Both parts can be tested separately before final assembly of the whole C-meter.

Frequency Counter and Display with Overflow Indicator

This unit is mounted on a single-sided printed circuit board 110 by 80 mm. Using a single-sided printed circuit board for such a complex circuit results in a few jumpers being necessary. However, the use of double-sided printed circuit board would not be fully justified – it would be much more difficult and expensive.

This unit is basically a 4-stage frequency counter with overflow indicator, which reacts only to every second pulse from the last decimal counter as explained earlier. Decade counters used are SN7490, with the exception of the first one, which must handle frequencies around 40 MHz. An SN74196 is used here instead, as it can handle frequencies over 50 MHz. Latches SN7475 and BCD-to-seven-segment decoders SN7447A are used to drive 7-segment incandescent displays (Minitrons) of a cheap foreign make, type 3015-F. If any other type of 7-segment display is used, you must check to see if the pin arrangement is the same. If not, the printed circuit board must, of course, be modified accordingly. The overflow indicator uses an SN7473, one surplus plastic switching transistor and an LED (TIL209 or similar).

I used IC sockets for the Minitrons only (MOLEX type); all the other integrated circuits are soldered directly into the printed circuit board. With surplus integrated circuits this is a bit risky – the decision is yours.

There are four resets for the counters, as well as one for the overflow indicator and strobe for the latches. Two wires are for switching the decimal point of the second Minitron for the higher range.

Oscillator, Gate, MMV and Timing Circuits

I tried a few types of harmonic oscillators and the most successful is shown in Fig. 3. It is reasonably stable and the output voltage is high enough to drive a buffer stage, which drives high speed gate IC14A (SN74HOO). Crystal X is a harmonic type (3rd or 5th harmonic) and *any* frequency between 35 and 45 MHz is suitable. Coil L1 has 10 turns of 28 SWG enameled wire on a 5 mm diameter with a tuning slug. Capacitor C_O tunes with L1 to the harmonic frequency of the crystal X. The coupling coil is 2 turns of insulated wire (24 SWG) over the "cold" end of L1.

The buffer stage Q3 must safely drive the buffer gate IC14A. The easiest way to check if IC14A is driven enough is to measure the

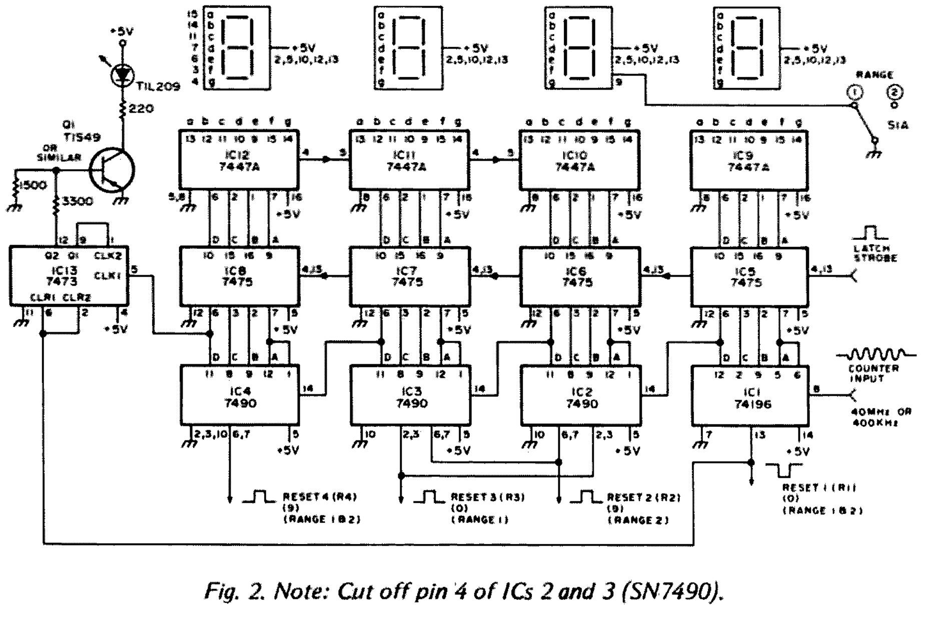


Fig. 2. Note: Cut off pin 4 of ICs 2 and 3 (SN7490).

rf voltage with an rf diode voltmeter at pin 11 of IC14. If the rf voltage is low or unstable, I recommend that you change the value of the base resistor of transistor Q3 or the transistor itself. Unstable or low rf voltages (e.g., under 2 V) will result in unstable or no display of the measured value of capacity. So get it to work one hundred percent. This is probably the only difficult part of the whole instrument.

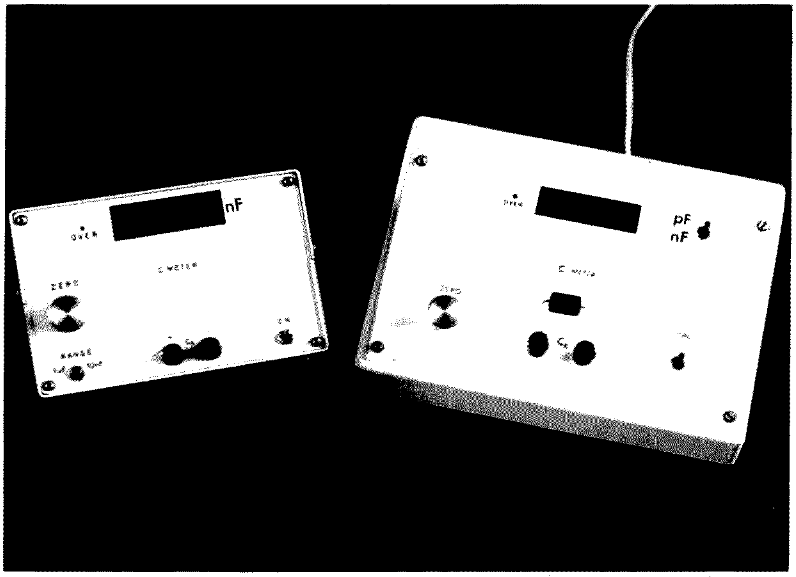
The rf output from IC14A is fed into another gate IC (14B) and divided by 100 (IC15 and IC16). Range switch S1B blocks IC16 for range 1 via IC20E, so that at the output (pin 11) of IC16 there is logical "1". At the output of IC14C (pin 3) is a 40 MHz signal. If the range switch S1B is in position 2, gate IC14B is blocked, the output (pin 8) is logical "1", IC15 and IC16 divide the 40 MHz by 100, and the 400 kHz output (pin 11 of IC16) goes via IC14C to pin 4 of the gate IC14D.

One half of IC17 (dual Schmitt trigger) works as an oscillator; a 47 uF 10 V solid tantalum capacitor and a 470 Ohm resistor make up the timing circuit for approximately 20 Hz. This frequency is fed into IC18 (an SN7490 decade counter). The B, C and D outputs of IC18 are used to produce trigger, strobe and reset pulses. Trigger pulse "4" from pin 8 of IC18 is reshaped in the second half of IC17 and fed into IC21 (the SN74121 MMV), which produces a pulse with length directly proportional to the value of capacitor C_X (+C_F). This pulse (at pin 6 of IC21) is used to enable gate IC14D. The output from IC14D (pin 6) goes to the counter input.

Strobe impulse "6" is formed by the B and C outputs from IC18 (the decade counter) in the gate IC19B (SN7400). The output is a negative impulse and, as the SN7475 latches require positive pulses, it is inverted in one of the hex inverters (IC20B) of SN7404.

Reset 1 and 4 pulses are common for both ranges. The D output from IC18 goes via IC19A to Reset 1 (negative pulse). Reset 2 must be a positive pulse – thus, Reset 1 is inverted in IC20A.

For range 1, the Reset 3 pulse must be positive. With S1B in position 1, gate IC19C is open but the output pulse is negative – it is therefore inverted in IC20C. The Reset 2 output is logical "0", as IC19D is blocked.



Two versions of the C-meter.

Get the buffer stage to work one hundred percent – this is probably the only difficult part of the whole instrument . . .

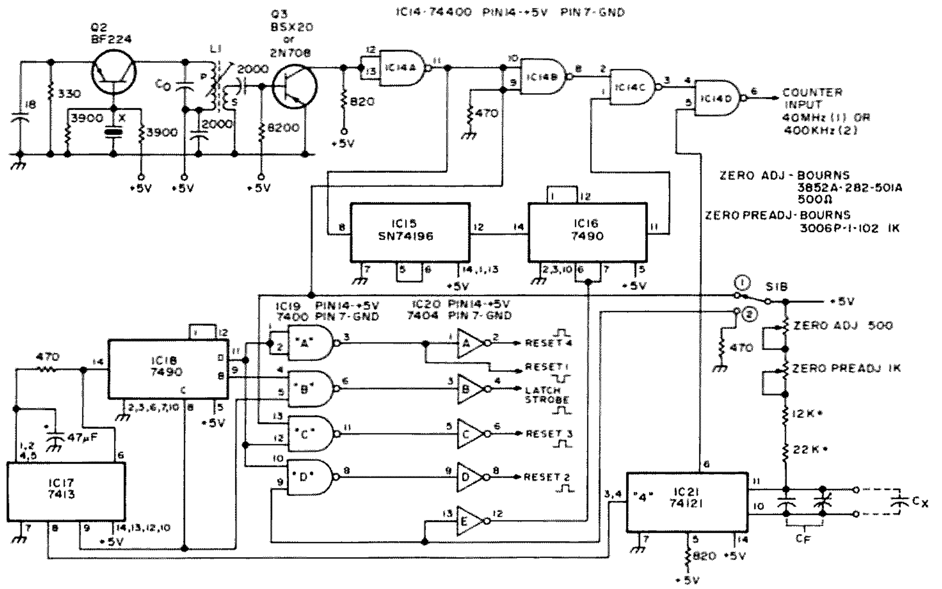


Fig. 3.

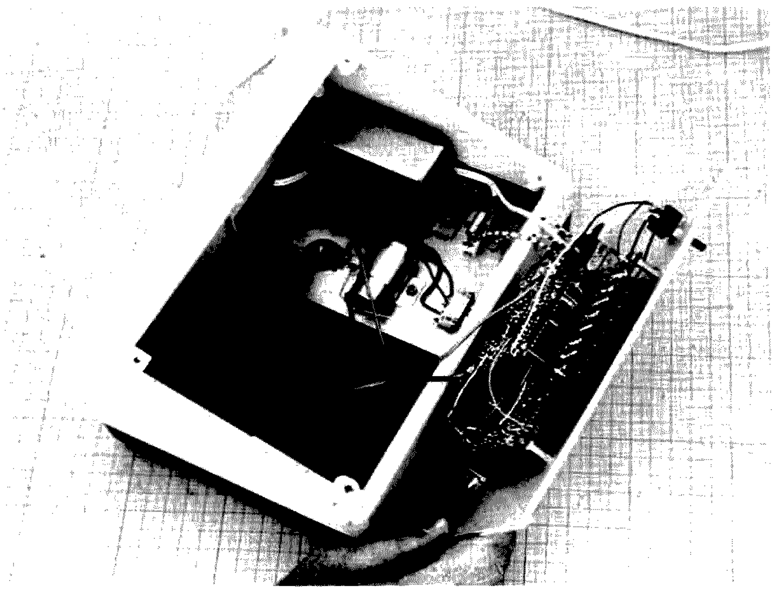
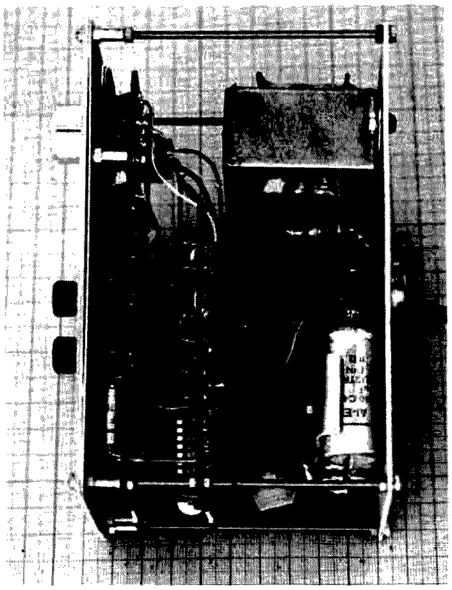


Inside view of the C-meter in the plastic box.



Inside view of the C-meter in the metal case.

For range 2, the Reset 2 pulse must be positive. Switch S1B is in position 2 and gate IC19D is open, while IC19C is blocked and the Reset 3 output is logical "0".

Power Supply

The last part of the C-meter is the power supply. It is very simple, thanks to IC22 (MC7805CP). This integrated circuit has built-in overcurrent and thermal protection and is a very good buy for the money. The output voltage should be very close to +5 V (according to the specifications ± 0.2 V, but I have not found any worse than ± 0.1 V). It is rated for 750 mA minimum (short circuit current limit) and this value just suits our requirement (about 700 mA with display "8888"). The typical input-output voltage differential of the MC7805CP is 2 V, but to be on the safe side I used 8 V ac. With a large smoothing capacitor the input voltage is over 9 V dc. Do not try to go under this value (at nominal mains voltage); otherwise, when the mains voltage drops, you are in trouble.

A small capacitor across the output improves transient response. The connection between the 5000 uF and the input of IC22 should be as short as possible. Use heavy wires – they eliminate voltage drops and improve stability.

To suppress spikes from TTL integrated circuits, it is essential to connect a few capacitors of 0.1 uF and 50 or 100 uF tantalum at intervals on both printed circuit boards. The 0.1 uF capacitors are Siemens, type B32540-A3104-J metalized polyester. Their advantage is very low inductance, but even the ceramic disc capacitors will do the job. Be careful about the polarity of tantalum electrolytics; I was not – fortunately the MC7805CP has good protection.

By the way – the IC22 regulator needs a heat sink to dissipate about 3 W. A small piece (100 x 100 mm) of 2 mm (approximately 14 gauge) aluminum is more than adequate; if a metal box is used, just mount the regulator on the rear side of the box.

Construction

Mechanical construction is probably the weakest point of most of the amateur equipment. Not everybody has a well-equipped mechanical workshop. I built two C-meters, each one of different construction. I hope that will give you enough inspiration.

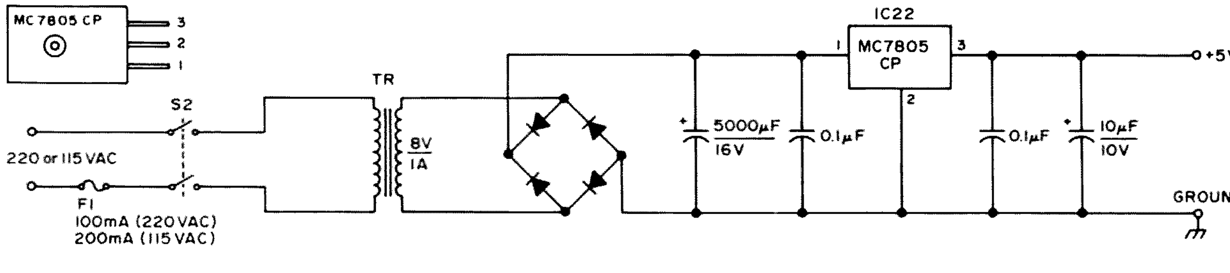


Fig. 4. Note: MC7805CP mounted on a heat sink.

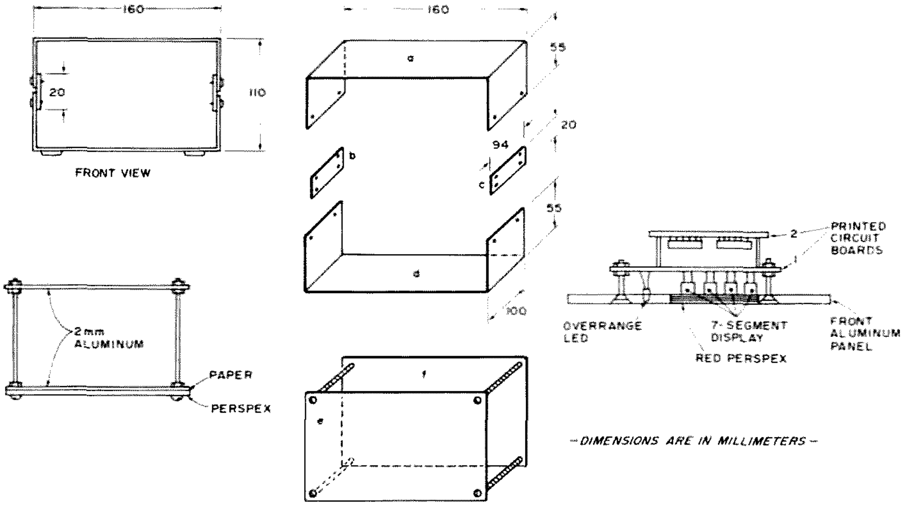
Fig. 5. Construction details.



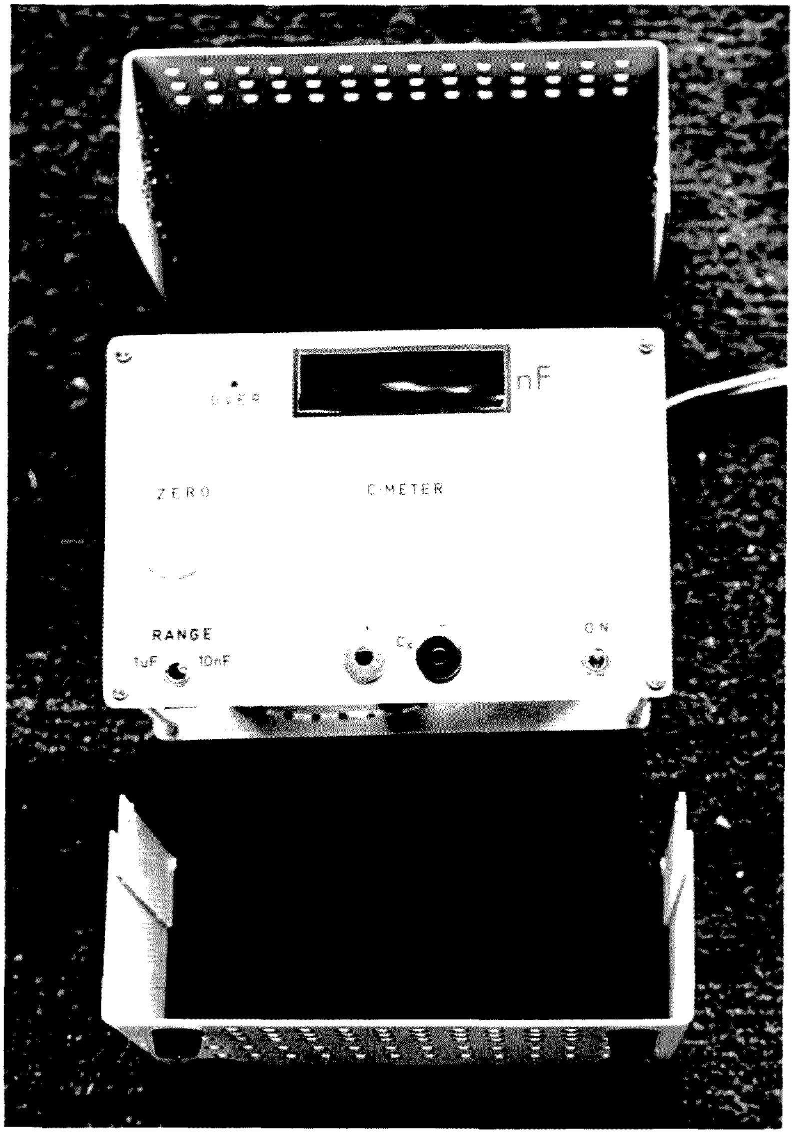
The first prototype was built into a homemade cabinet; the basic dimensions and the general idea are shown in Fig. 5 and the photographs.

U-shaped parts *a* and *d* can be bent in a big vise. The other parts are very simple. Aluminum (2 mm, 14 gauge) can be used for all parts of the cabinet. Start with parts *a*, *b*, *c* and *d*, and then measure the inside dimensions and cut front and back panels *e* and *f* accordingly. (In my case I used steel, and parts *b* and *c* are spot-welded to part *d*.)

The front and back panels are held 94 mm (inside dimension) apart by means of four 4 BA screws 102 mm long. This sub-assembly is then inserted between the two U-shaped parts *a* and *d*. Parts *b* and *c* prevent the front and back panels from moving, and hold parts *a* and *d* together.

After drilling all necessary holes into the front and back panels, clean the front panel and mark all holes with a pencil on a piece of thick white paper which does not change its dimensions with moisture. A white plastic sheet would be even more suitable. Cut off all the marked holes with a sharp knife. Use transfer letters (Letraset or similar) for descriptions of the functions on the panel. Then cut a 1.5 mm thick piece of clear Perspex (Plexiglas) and drill all holes with the exception of the ones for display LEDs and overrange LED. Cut a piece of red Perspex (3 mm thick) which will fit exactly into the hole for the LED display in the front metal panel *e*.

Perspex is supplied with paper sheets glued on both sides. Do not remove these; mark all the holes and outside lines with a pencil and then make cuts with a sharp edge along the outside lines, about 0.2 mm deep. I used the sharp edge of a small chisel (along a steel ruler) with success. Do only one cut at a time. Break both ends of the cut slightly



Mechanical construction of the homemade metal case.

The future accuracy of the instrument depends on the accuracy of this 5000-10,000 pF capacitor, so have a good look around for it . . .

with your fingers. Lay the Perspex over the edge of the bench and break carefully. I recommend that you try this procedure a few times on Perspex off-cuts. The operation is not difficult but does require a bit of practice.

Drilling of holes in Perspex is also a little difficult. The best method is to use a drill press with a maximum of 500 rpm. A bit of practice on a piece of off-cut is not a waste of time. Only after drilling all holes, cutting the right dimensions and smoothing the edge with sandpaper should you remove both paper covers and wash the Perspex with soap and water. A front panel made this way looks professional and is really worth the effort.

The printed circuit board with LEDs is fitted parallel to the front panel by means of four screws with countersink heads, so that they are covered with the paper and not visible.

Both terminals for C_X must be made from a good insulator or fitted on a piece of Teflon (PTFE). Perspex tends to absorb moisture from air – a bad insulator will cause erratic readings.

The transformer, IC22 and the 5000 uF electrolytic capacitor are fitted onto the rear panel. Use a small transformer (or increase the depth of the box), so that it does not interfere with the printed circuit boards.

For my second construction of the instrument I used a ready-to-use plastic cabinet with a metal front panel. This is the lazy man's construction and it is, of course, less mechanically difficult. Due to the bigger size of the box, it does not need the cooling holes that proved to be necessary in the previous construction. The construction of the front panel is the same as in the previous case and I hope that the photos are self-explanatory.

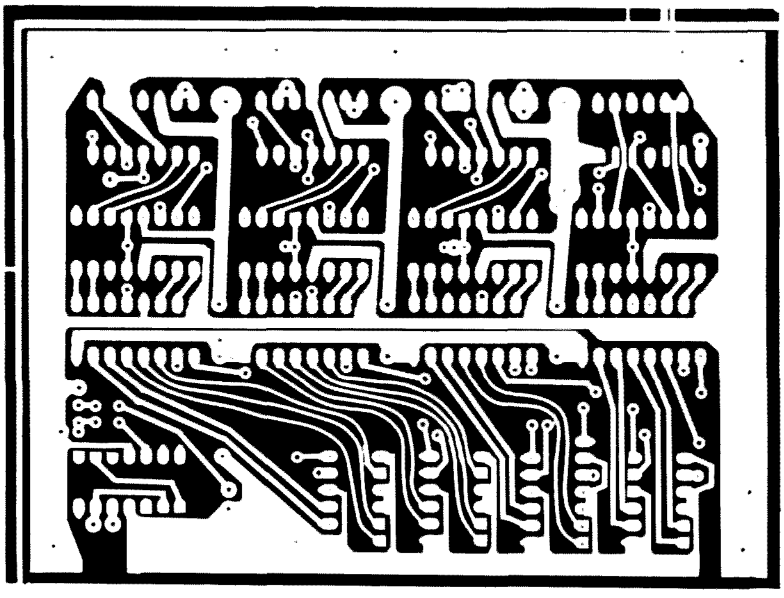


Fig. 6. Counter and display PC board (full size). Copper in white.

Fibreglass printed circuit boards should be well washed with soap and water after etching, rinsed, dried and polished with steel wool. Then spray both boards with soldering varnish and let them dry in the oven. I am sure that your wife will be very pleased with the pleasant smell of the varnish in the kitchen. Anyway, this protection is very important; otherwise, after a few years you might be surprised to find that your C-meter does not work. Only after this procedure can you start drilling the holes into the printed circuit boards. Holes 0.8 mm in diameter are adequate for all components and wires, except the five thick interconnecting wires for the ground and +5 V.

Soldering should be done with a small soldering iron – preferably temperature controlled. Start with the jumpers; a few long ones should be insulated wire, while the others can be bare wire 0.6 to 0.8 mm in diameter. Then solder the components and integrated circuits. Be sure that all integrated circuits are positioned the right way. Do not forget to cut off pin 4 of ICs 2 and 3 (SN7490), before soldering them onto the printed circuit board.

You can test each printed circuit board separately. Use your laboratory 5 V power supply or the one for the C-meter. The current consumption of the frequency counter part with display is approximately 500 mA; of the second part, around 200 mA.

To test the counter subunit, Resets 2, 3 and 4 must be grounded, and Reset 1 must be connected to +5 V. Then connect a square wave generator to the counter input. A circuit of the timing oscillator IC17 (SN7413) can be used (use pin 6 as output). The display will start counting at a random number and will continue to over 9999 and 0000 again.

The second part of the C-meter can be checked with a frequency counter (output from IC14D pin 6). You must, of course, simulate the function of the range switch S1B. Output frequencies (at pin 3 of IC14C) must be exactly at the ratio of 1:100. The latch and reset pulses can be checked with an oscilloscope or, preferably, with a logic probe. The sequence and dependency of the output pulses on the position of S1B was described above.

Alignment

If both parts of the instrument work satisfactorily, solder the two printed circuit boards together. Five thick wires should be soldered onto the counter board; to make

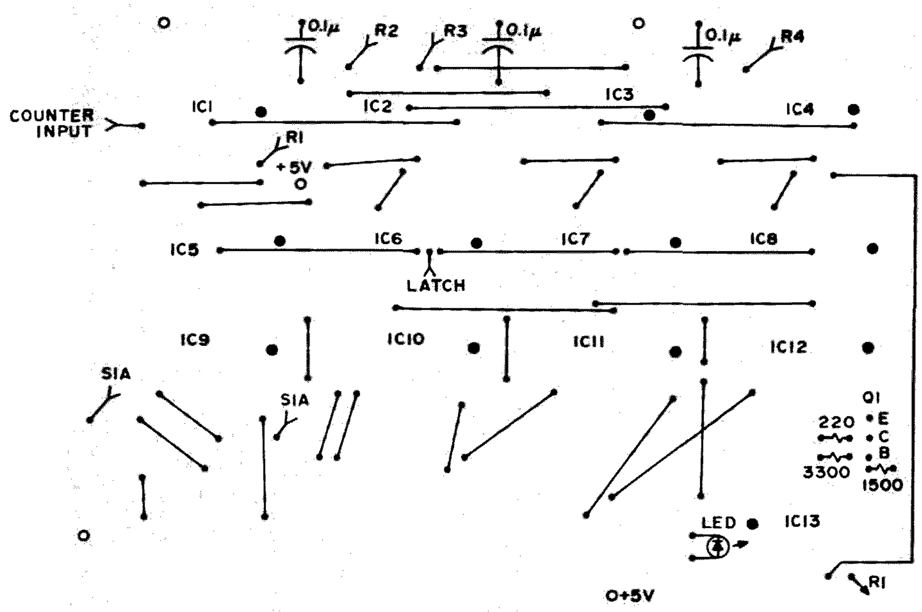

Fig. 7. Component layout, counter and display PC board.

Take advantage of this instrument — it measures with practically full accuracy within a second of being switched on . . .

this operation easier, use differently colored insulation on the interconnecting wires. The same applies to the range switch wiring.

Check the output voltage of the power supply. If possible, load it with a 6.8 Ohm resistor to check if the output voltage is stable. This checking is important, as any voltage over 5.25 V can damage some integrated circuits. Then check the current consumption of the whole unit. It should be under 0.75 A. If everything is OK, you can start with alignment.

Set "Zero Adj" (ZA) and "Zero Preadj" (ZP) to the center positions. Solder a few (2 or 3) capacitors, which are stable with temperature, across the C_X terminals (inside the cabinet). I used plastic molded silver mica and polystyrene without serious problems. In parallel, solder a small mica trimming capacitor (20 to 50 pF). The total value of all of them should be about 980 pF. They form capacitor C_F.

The difficult problem here is to get hold of a very accurate capacitor whose value is between 5000 and 10,000 pF. The future accuracy of the instrument depends upon the accuracy of this capacitor. So have a good look around for it. Note that either input terminal is grounded. Of course, the one marked "+" is not very sensitive to hum, etc.

With no capacitor C_X you should be able to adjust the instrument to show zero on the display, with the values of resistors 12k* and 22k* next to ZA and ZP. But if you used a crystal of a frequency lower than 40 MHz, these resistors will be slightly higher in value (say 33 and 10k) and vice versa. By the way — they must again (like ZA, ZP and C_F) have a very low temperature coefficient. It is best to start with ordinary resistors and replace them, after finding the right values, with high stability ones.

Anyway, adjust zero with ZP, and then connect the precise capacitor C_X. If it reads low, adjust capacitor C_F to the lower value.

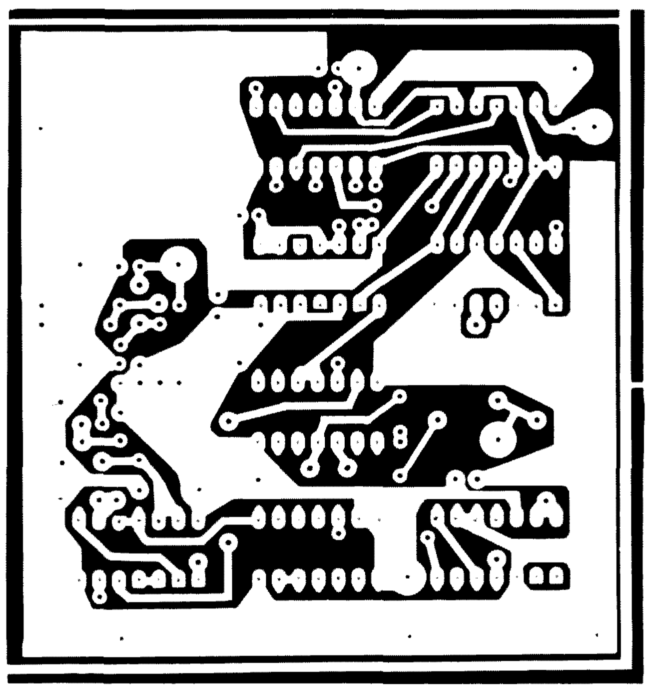

Fig. 8. Oscillator, gate and timing circuits PC board (full size). Copper in white.

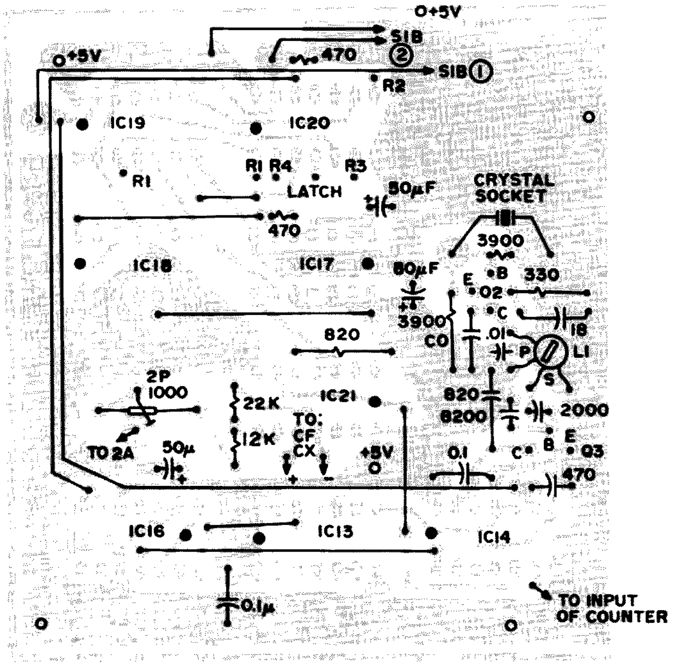

Fig. 9. Component layout, oscillator, gate and timing circuits PC board.

Remove C_X and adjust zero with ZP (changing 12k* and 22k* if necessary). Try it again with C_X and adjust C_F. Remove C_X and adjust the zero with ZP. (Basically, when the display shows a low value, you must lower the value of C_F – and vice versa.) Continue in this way until the display shows zero without C_X and the right value with C_X. During this procedure ZA is adjusted to the middle position. And that's it. Now you can take, say, twenty mica or polystyrene capacitors 200 to 500 pF, measure each one of them, mark the value and add them one after another in parallel on the terminals of C_X. The difference in total readings should at any point be not more than ± 2 digits. If more, then the insulation between terminals 10 and 11 of IC21 (MMV) or between terminals C_X is bad and must be improved.

This procedure, of adding measured capacitors in parallel, demonstrated the excellent linearity of the SN74121 MMV. Originally, when I started the construction of this instrument, I did not expect such good results. It is really amazing how these small plastic 14- and 16-legged spiders perform.

The higher range 2 does not need any alignment, as it is automatically OK when the lower range 1 is adjusted.

Conclusion

Inside the cabinet, the integrated circuits, display, IC22, etc., dissipate over 5 W. Certain crystals tend to be unstable at the high temperature which can develop when the instrument is switched on for a long period of time. In this case, I recommend that you drill a lot of small holes in the top and bottom of the cabinet in order to allow air to circulate along the printed circuit boards.

Take advantage of this instrument – it measures with practically full accuracy within a second of being switched on. Just adjust the zero by means of ZA (with range switch in position "pF," even when measuring in the nF range) and connect the capacitor across the terminals C_X. If you measure a lot of capacitors, check the zero from time to time, as it drifts slightly with temperature.

The overrange flickers when you exceed the range. This is much better than a steady signal.

If you are measuring solid tantalum capacitors, connect them with the correct polarity at terminals C_X. The polarizing voltage across these terminals is about 3 V dc. This low voltage limits accurate measurement to only low voltage electrolytic capacitors.

If the reading is not stable and changes by more than ± 1 digit, then there is something wrong with the capacitor and you would do best to throw it away. ■

The Computer QSO Machine

by
B. D. Lichtenwalner W1HAB
29 Michael Road
Stamford CT 06903

If you have ever operated RTTY for extended periods, I expect you have tired of repeated typing of your call in RTTY, then had to send your call in CW. You also included a time and date print on those special RTTY contacts that could help you toward WAS or DXCC. Were you slowed down in that contest when time was a required part of the text? Here is a small, easy to build circuit that will give you the ability to print the time and date, and sign your call all at the touch of a button.

During 1972 I became very interested in RTTY operations. Shortly thereafter my interests expanded to autostart operations. I was particularly interested in the automated devices that were operational at some of the stations such as WRU Answer Back (Who Are You – a short message sent when a station is called up with a pre-set access code) and Relay Systems. There were a few systems operational that printed the time and date of each WRU or Relay request.

As a result of seeing what was available I started designing a station control unit. First came an electronic "stunt box." Then a WRU using a Model 15 TD and finally a relay system with a well used FXDR. That time/date readout still held my interest – to be able to know when my station had responded to someone's request was a desired goal. Also a time/date printout would provide automatic logging of both received and transmitted messages.

The DDTMG (Digital Date/Time Message Generator) would provide the following functions:

–A programmable message generator using ROMs
–A time readout
–A date readout, with automatic updating – not manual
–A CW generator to meet legal requirements for CW identification

The circuit design would have to use available TTL circuits and would have expandable capabilities for tieing into a complete system approach, using a stunt box electronic equivalent for control.

The circuit consists of the following four basic elements: an electronic clock/calendar, a parallel to serial converter, a memory bank made up of read only memories (ROMs), and a translator/de-multiplexer to convert the output of the clock to Baudot code.

The digital clock is a straightforward application of one of the medium scale

The circuit board used for the digital clock. This portion of the project alone is a useful accessory to the shack. The seven transistors in the upper right corner are current amplifiers for the segment lines, the five transistors on the left and one in the lowering right hand corner are the digit select drivers. Molex pins were used to make up the socket for the CT7001.

integration chips currently on the market. The chip develops all the necessary information to indicate both time and date. The 7001 chip also has a built-in backup oscillator that will allow the chip to maintain the proper time even if ac power is interrupted. A battery supply is needed to obtain the necessary operating voltages, however. In normal operation this chip displays time for 8 seconds then switches to date for 2 seconds. Provisions are made within the chip to force display of either time or date as requested. This is an important feature for operation of the DDTMG.

The clock uses internal circuitry to keep track of the month. It also keeps track of how many days will need to be counted before advancing the month counter. February 28 always advances to March 1, except the designers of the chip allow February 29 to be set manually into the counter for leap year. This is only 1 day in 4 years when manual setting of the clock will be required.

The 7001 chip is designed to drive either 4 or 6 seven segment LED readouts. The first 4 LED readouts indicate hours/minutes or months/day. The fifth and sixth digits are used in time mode only and indicate "seconds." The "seconds" digits are not used in the Baudot converter. Information is taken from segments A, B, E, F and G to feed to the Baudot converter. Signals indicate which digit is being strobed, and are required by the de-multiplexer.

The circuit shown has driver transistors on the segment lines to provide additional drive to the LEDs. In the first version of the clock the LEDs were not bright enough to suit me so this slight addition was made. This portion of the project can be built as a stand-alone electronic clock and would be a great addition to most shacks.

Parallel to Serial Converter

The function of this unit is to take parallel information from the memory bank and present it in serial form to the RTTY

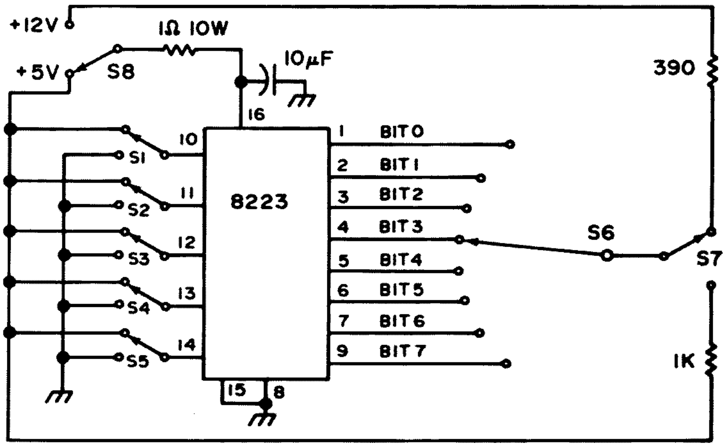

Fig. 2. 8223 programmer. Circuit source: Signetics Data Book, *1974, pages 4-11.*

loop. The basic timing pulses come from a U12. This unit has components selected to operate at 91 Hz. U20A gates the pulses from the generator to a set of frequency dividers consisting of U1, U2 and U3. The output of U2B and U3 are connected to an 8 line to 1 line multiplexer, U4. This approach was used by K4FUP and W4VWS in their message generator 1. This circuit will take the data presented to the input pins and will in sequence place successive bits on the output line to be fed to the RTTY loop for keying. The speed at which data is fed from the multiplexer is selected by section one of U9. For RTTY the output pulses are each 22 ms. For CW mode the two additional dividers are inserted in the divider chain by the switch action of U9. The speed is selected by the control line from the CW control latch (U17C and D). Each CW element will be 88 ms long. If the printer is left in lower case his speed will print a rather neat-looking string of 0s across the page as the CW ID is sent.

Sections two, three and four of U9 act as data switches to the multiplexer, chip U4. Their function is to force the start bit of each character in RTTY mode to a space, and to force the stop bit to a marking condition in RTTY mode. In CW mode information bits 0, 6 and 7 from the memory bus are switched to the multiplexer.

The circuit is placed in run mode for RTTY by actuation of RTTY run latch consisting of U17A and B. The start signal can be any negative-going pulse that reaches a level below 0.8 volts. This can be a switch closure as shown, a transistor (NPN) or a signal from some external TTL circuit.

U17C and D are similar to the RTTY run latch. Interfaces, similar to the RTTY run latch, are used for turn on. This latch when turned on will reset the RTTY latch. Provisions are made for resetting of this latch, as well as the RTTY latch from an external signal. The CW latch being turned on will fire the single shot, U5, that will allow a pre-wired address to be loaded into the memory address counter. This procedure will be explained later in the memory section.

The five data bits that represent the Baudot characters that are to be sent to the serializer, U4, are run through a five pole double-throw electronic switch consisting of

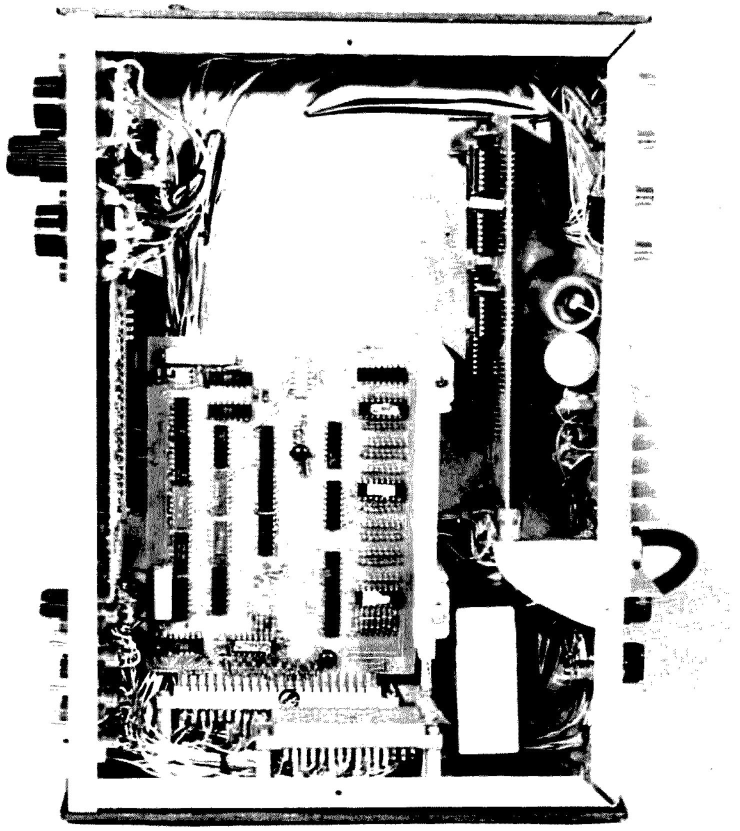
Fig. 4. Addressing sequence for 8223 memories. 0=0 volts; 1=+5 volts.



Inside view of K1ZPX cabinet. The circuit board for the clock is shown edgewise toward the front of the cabinet. The main DDTMG board is shown supported by a card guide toward the back edge. The vertically mounted board toward the rear is the timing board for the UT-4. The sockets above the DDTMG are for the other UT-4 boards. Power supply for both units is built on a small board fastened to the back of the unit.

U10 and U11 A and B. This switch is controlled by U18B, a circuit that recognizes if data should be coming from the memory or from the digital clock circuitry. More on this later.

Memory Bank

The memory bank consists of up to 8 read only memories that can contain up to 32 RTTY characters in each memory, or a CW message. The typical CW ID message used for RTTY, consisting of DE and station call, takes approximately one half of a memory chip.

The key to any memory system is in knowing where data is located. This information retrieval scheme is known as "addressing." The "addressing" scheme for this circuit consists of two 4 bit counters U6 and U7. U6 and U7A are used to address the control lines on the 8223 ROMs. The particular 8223 that is to be selected is enabled by the output of the proper line from U8. This circuit converts the binary count of U7B, C and D into a one out of eight activated line.

The RTTY message will begin at address 00000000, the address that is forced into the counter at the start of each RTTY message. The CW message can be loaded at any convenient address, preferably at a high address in the scheme. That starting address of the first character of the CW message is "wired" to the input lines of the counter. For my generator the CW message is contained in the last chip in the memory bank, so starts with address 11100000. To place this address into the address counter the preload pins of U6, A, B, C, D, U7A are "wired" to ground. The preload pins for U7B, C and D are "wired" to plus 5 volts through a 1k resistor. When the CW message latch is turned on, U5 fires and loads the "wired" address into the counter. The preload pins have been brought to the edge connector of the circuit board used for this project for ease of wiring and to allow later expansion of control circuitry to increase the flexibility of this unit.

The output of the memory bank will be used 3 different ways. First, bits 1, 2, 3, 4

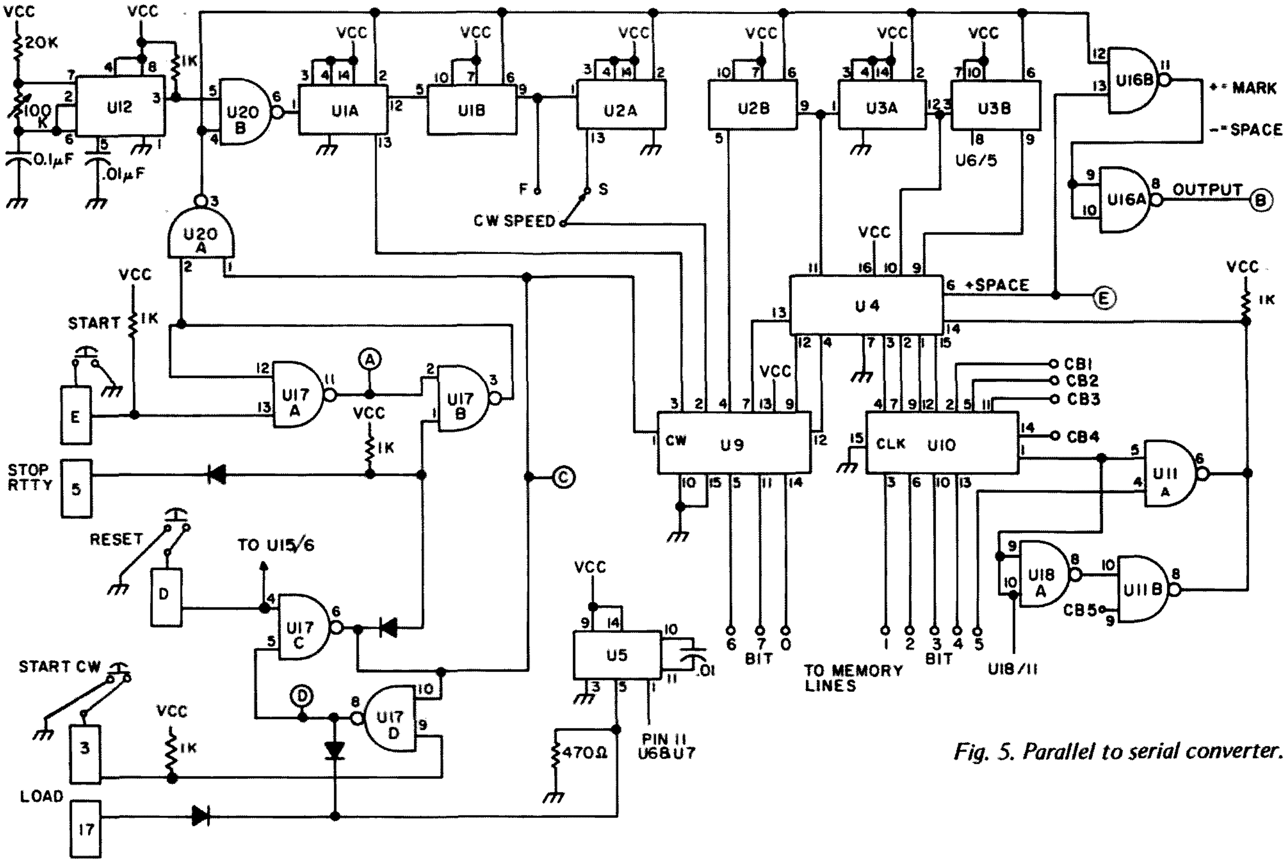


Fig. 5. Parallel to serial converter.

and 5 will be used to indicate the RTTY message to be sent. Second, all bits will be used to encode the CW message; and third, in RTTY mode when bit 0 is coded as a "1", the memory will be used as a control function generator. Also, if bits 6 and 7 are "1"s when in the RTTY mode, the generator will change to CW mode and load the "wired" address into the address counter indicating the starting address of the CW message. When in CW mode the recognition of bits 3, 4, 5 and 6 will indicate the end of the CW message. These end sequences are recognized by U21 and U15 respectively.

Translator/De-Multiplexer

The function of this circuit is to select the proper digit from the digital clock, translate the seven segment code (only five segments used in the translator) for that digit into RTTY Baudot code, place it into latches and switch it onto the serializer input lines. Let's look at what the circuit does to accomplish these functions. To signal the circuitry that a RTTY character is required from the clock, bit 0 in the memory is coded as a "1". U18B combines the plus on the bit 0 line and the RTTY latch being "on" and forces the switch U10 to take its output from latches U14 and U19. The information that is resident in the latches comes from the translator U22. The translator is available from Kelly Associates.*

The clock segment information is being changed at better than 100 kHz for each of the digits. To determine when the proper digit is available at the output of the translator, U22, we need to look at a bit more of the control circuitry. Again, in the mode of operation when the clock information is to be sent, the memory bank is being used as a control memory. As a result, the data from the memory that is usually sent to the serializer is "unhooked" since U18B has detected that we want a digit from the clock/calendar. To tell us which character is required, bit lines 1, 2, 3 and 4 are used to select which clock character will be gated to the latches U14 and U19. Let us see how the circuit operates. First, we decide that we want to "print" digit 1 from the clock. (This is the tens position of the hour or month.) We code bit 0 and bit 1 in the memory as a "1". U20C will now have pin 13 positive. When clock digit 1 (from the digital clock) goes positive, indicating the information on the segment lines is the data for digit 1, the output of U20C goes negative, forcing the output of U13 positive and firing the single shot, U30. This "opens" the gate on U14 and U19 and allows the data that is on the

*Kelly Associates, P.O. Box 2100, Glenbrook CT 06906.

output of U22 to be placed into the latches. Once this data is loaded, it is available for serializing through U4. The other digits are selected in a similar manner by gates U20D and U18C and D.

There are two additional sets of circuits that make the interface work properly. First, let's see how we select either time or date. Since digits 1 through 4 can be either time or date, the select circuits U20C and D and U18C and D are used for both outputs. The real trick is to force the clock circuit into either time or date mode as required for your printout. To do this we use a pin on the clock chip called IN3. If this pin is driven plus at digit 3 time, the clock will display time. If driven plus at digit 4 time, the date will be displayed. If you want to display time, code bit line 6 as a "1". This line being plus along with clock digit 3 being plus will gate U11C and its output will go negative. When it does, up goes the input on IN3, and up comes the time. Bit 7 does the same thing for date. To keep the clock from really showing funny numbers during a CW message when bits 6 and 7 are used as data bits, Q2 was added to make sure the output to IN3 would stay at ground potential.

To be able to set the last digit of the year for the readout the U16D circuit was added. When you want to print out the last digit of the year, place bit 0 and 5 at a "1" level. This forces the data to come from latches U14 and U19. However, bit 5 deactivates the translator U22. Instead of translating a character from the digital clock, all input lines to U14 and U19 will go plus. To input data, the output of U16D is connected to the bits required to represent the digit required. For 1975 the "5" is coded by connecting a diode as shown between the U16D output and the input to the 5 bit latch. For next year when a 6 is needed, diodes will be required between bits 1, 3 and 5. The first digit of the year data must be coded in the 8223 memory.

The input of the data from the clock is translated to TTL level signals with a resistor network consisting of a 2.2k resistor in series with a 1k resistor and taking the signal from the junction. This design is not optimal for the design criteria for TTL logic, but has worked very successfully in this circuit.

The output of the circuit is interfaced to the ST6 with a very simple circuit. The output of U16A is run to an NPN transistor

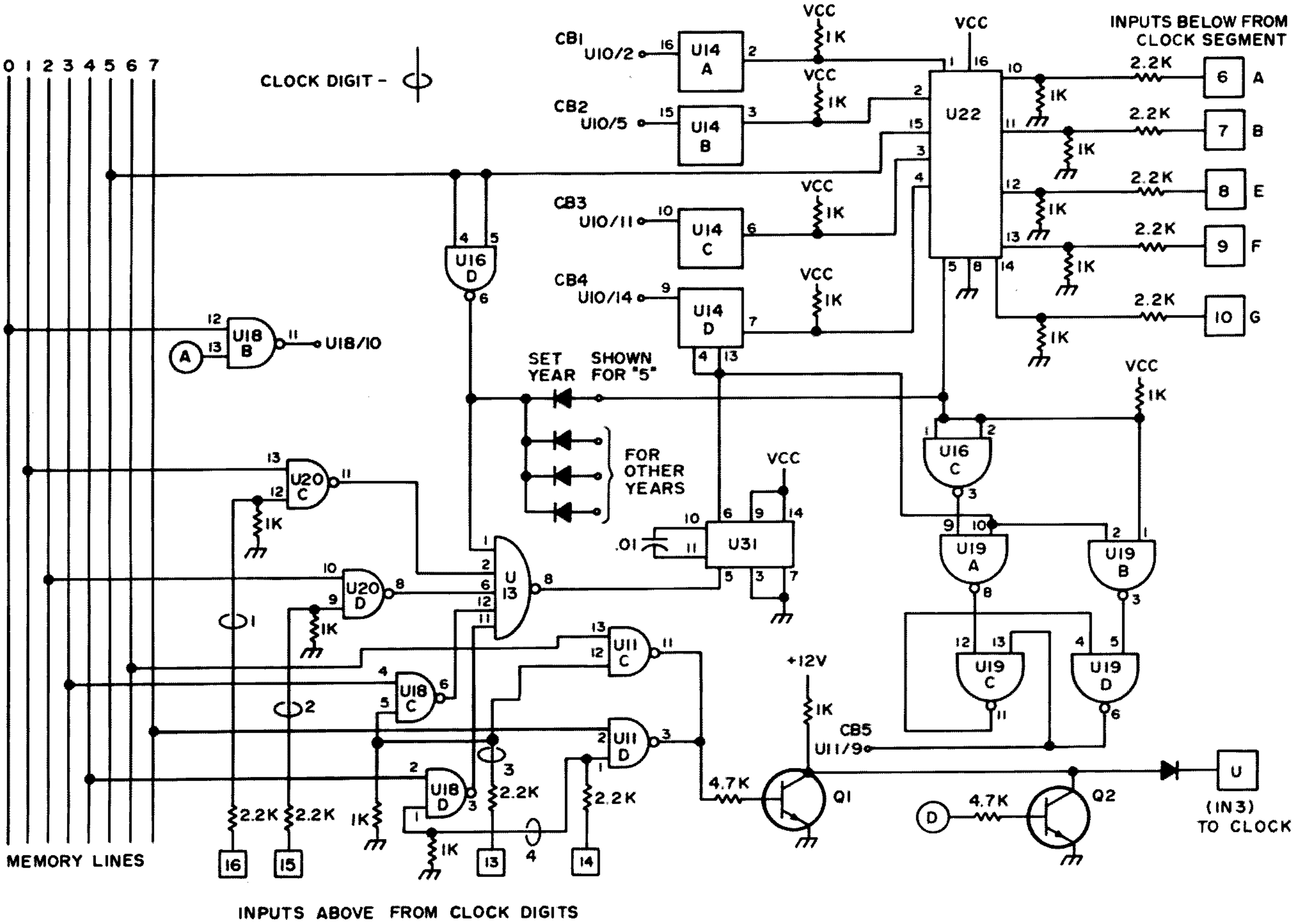

Fig. 6. Translator/de-multiplexer.

with a 4.7k resistor in series with its base. The collector circuit is connected to the base of the loop-keying transistor. Works every time.

Power Supply

The DDTMG requires a power supply that can deliver 5 volts at 1 Amp and 200 mA at 12 to 18 volts. The 5 volts requirement is best met by using the very conveniently packaged LM309K. Be sure to attach the LM309K firmly to the cabinet to aid in dissipating the heat from the circuit. A small U-shaped fin would also help to keep the unit cool. Diodes DX, battery BT and resistor R1 in the power supply can be eliminated. These components allow the clock chip to continue operating should ac power fail. The battery will be charged whenever the ac power supply is operating. It is advisable to check the current flow into the battery when fully charged to assure yourself that it is not exceeding 1 or 2 mA when the nicad batteries have reached full charge. Adjust R1 to set this current level.

Programming the 8223 Memories

When unprogrammed 8223 ROMs are purchased, all of the outputs will be at a "0" level. A small programming fixture as shown in Fig. 2 is all that is required to program these units. To program the ROMs I use the following procedure as outlined in Signetics Data Handbook.

1. Ground pin 8, and remove Vcc from pin 16.
2. Remove all output loads.
3. Ground the chip enable line, pin 15.
4. Address the location to be programmed by selecting the address using the five SPDT switches. For address 00000 all switches will be at the ground level. Address 00010 would be selected by placing switches 1, 3, 4 and 5 at the ground level and switch 2 at the plus 5 volt level. In the addressing scheme, bits are addressed from right to left. The right most bit represents the least significant bit in the address and the left most bit represents the most significant digit. The table in Fig. 4 shows the sequence of addresses and their equivalent decimal value. Remember when programming a sequence of characters, the order of message must start in the least significant position of the memory and be located in increasing addresses.
5. Apply plus 12 volts to the pin to be programmed through a 390 Ohm resistor. One bit is programmed at a time. The bit to be programmed is selected by switch 6. This technique will be applied only to those pins that must be at a "1" level at the end of the programming process.
6. Apply plus 12 volts to pin 16 for as short a period of time as possible.

Completed clock. This control unit built by K1ZPX houses the DDTMG, a UT-4, the necessary power supply, and switching circuits to select interfaces to several receivers and transmitters.

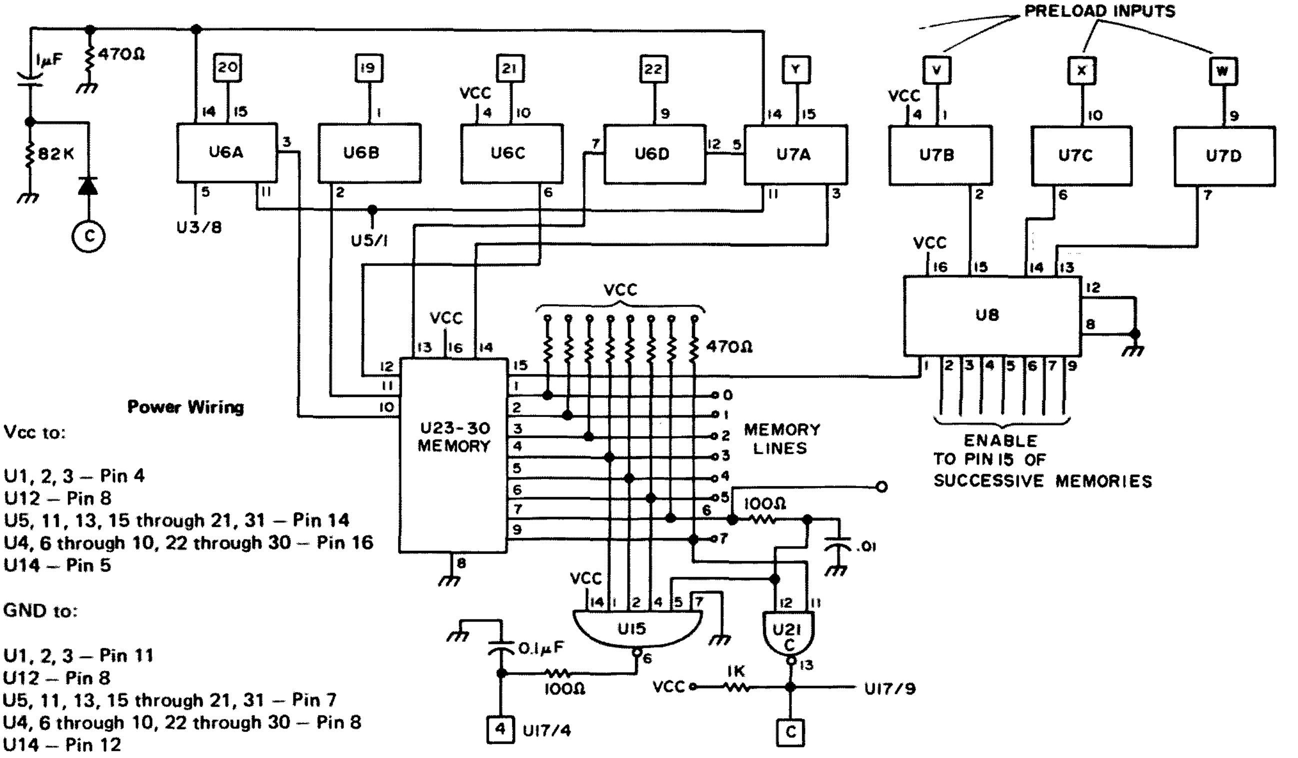

Fig. 7. Memory bank. Note: .01 bypass required for every 4 chips between Vcc and GND. U23 through U30 are 8223s in parallel, with only one shown. Only pin 15 is connected to separate enable lines.

7. Verify that the bit has been programmed by checking the output voltage across the 1k resistor with switch 7 in the verify position.

8. Continue to the next bit to be programmed at this address. When all bits at an address have been programmed and verified, advance the address and program the bit pattern for that address.

9. If during the verification process, a bit has been found to be not programmed, repeat steps above.

This process is quite simple, but requires a great degree of attention. One bit in the wrong position or address and the chip is useless. There is no way of returning a bit to the "0" level once it has been programmed.

If you prefer not to program your own chips, Kelly Associates offers the service of programming to your specifications at a very nominal fee. A self-addressed note to them will bring convenient forms to help you lay out your message.

To prepare the data to be programmed into the memories, we will look at the RTTY message differently from the CW message. All RTTY information will be contained in bit positions 1 through 5. Bits 0, 6 and 7 are used as control functions. As a result it is important to keep these bits 0, 6 and 7 as zeros during the programming operations. The bits will be set at the one level for each space and at the zero level for each mark. The start and stop pulses will not be programmed. They are inserted automatically by U9. Any handbook such as "Ham RTTY" will show the code required.

Let's look at an example. To code the letter "A" into the first address of a memory, we progress as follows. Select the first "address" in the memory. This is represented by address 00000. The Baudot representation of the letter "A" is

MARK MARK SPACE SPACE SPACE.

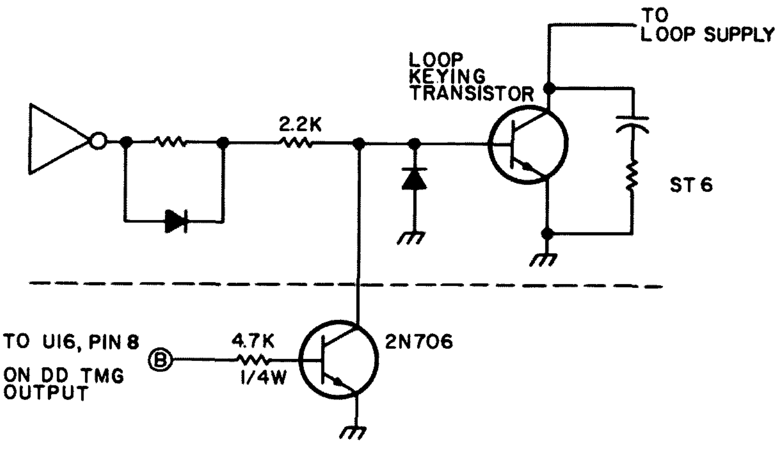

Fig. 8. Interface to ST-6.

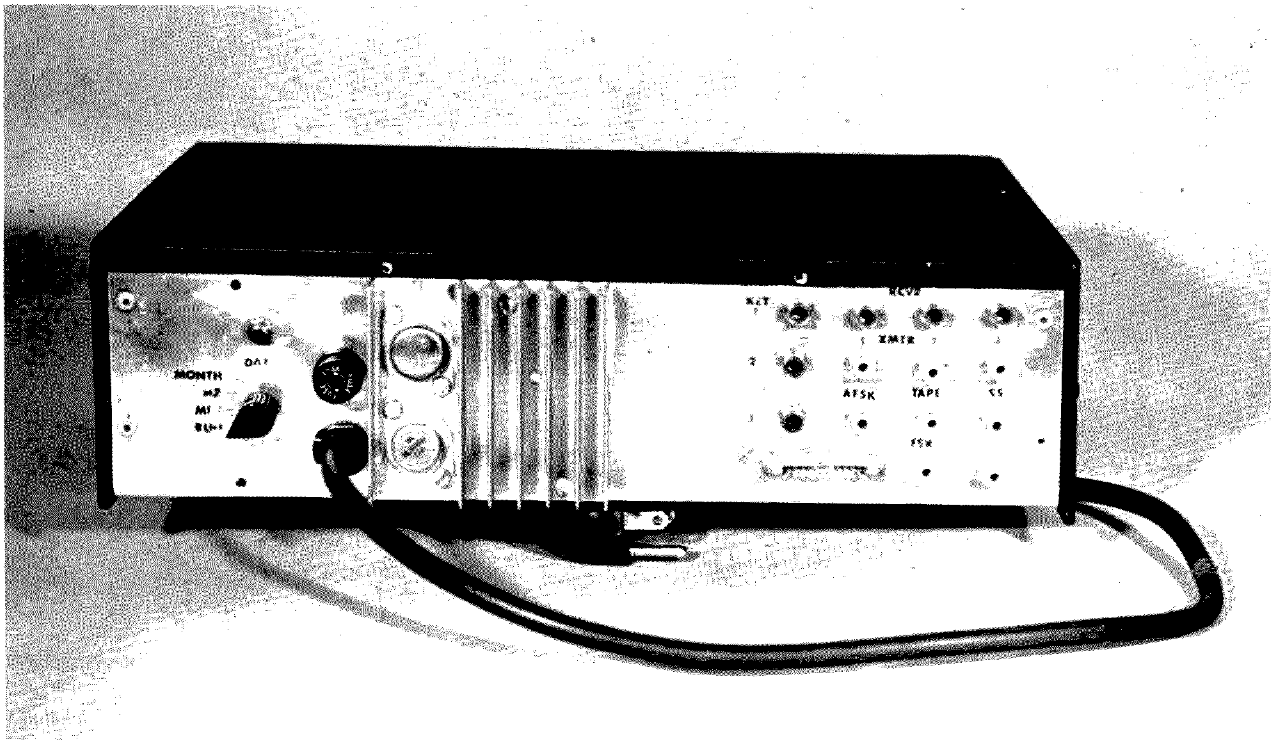

Rear view of K1ZPX DDTMG. The push-button and 5 position rotary switch on the left side of the panel is used to set the time and date on the clock.

This means that in the memory we want bits 1 through 5 to be set as follows:

bit 1	bit 2	bit 3	bit 4	bit 5
0	0	1	1	1

Again, remember bits 0, 6 and 7 will remain at 0 level. After completing the "writing" of the first character, advance the address to 00001 and program that character. Continue advancing the address switches to complete the message.

Programming of the time and date feature requires using the control bits 0, 6 and 7. Let's review what each of these bits controls.

Bit 0 at the 1 level in RTTY mode indicates that the data to be "printed" should come from the clock generator circuit rather than the memory bank. This is accomplished with the switch U10 and U11 A and B. When bit 0 is programmed to the 1 level, bits 1, 2, 3 and 4 select which of the clock characters are to be printed. Bit 1 selects the tens position of the month or hour – bit 2 at the 1 level selects the units position of the month or hour. Bit 3 selects the tens position of the day or minute, and bit 4 selects the units position of the day or minute. Bit 6 programmed at the 1 level will force the clock into the clock mode and bit 7 programmed to the 1 level will force the clock to display the date mode. To "print" the first digit (tens position of the hour) the following character would be in the selected address:

bit 0	bit 1	bit 2	bit 3
1	1	0	0

bit 4	bit 5	bit 6	bit 7
0	0	1	0

To select the digits of the time output, successive addresses in the memory would be identical to the above line except the 1 in bit position 1 would be replaced by A 0, and the 1 would be placed successively in positions 2, 3 and 4. To indicate that a TTY message is ended, bits 6 and 7 are both set to the 1 output.

Programming the Memories for CW

In the CW mode all 8 bits of the memory are used in coding the message. The message is laid out as shown in Fig. 1. Each Morse element is coded as a "1". A dot consists of one Morse element, a dash consists of three Morse elements. Inter-element spaces require one Morse element while inter-character elements require three Morse elements. The spacing between words is equal to seven elements. All spaces are programmed as "0" level in the memory.

The message is started at the address chosen for CW message. Bit 0 represents the first Morse element. I recommend at least

one address (8 bits) be left at the zero level to set off the CW message at the beginning and end of message. The first bit of the message is placed in the bit 0 position. The next element is placed in bit 1 position and so on through the memory. When the bit 7 is programmed, advance the address one count and continue the message starting at bit 0 for that address. Progress through the entire message until the complete CW message is programmed. Then allow at least one full address as blanks (0) level, then code the end of message character. This character consists of the 3, 4, 5 and 6 bits being coded as "1"s.

Construction

The easiest method of construction uses the circuit boards available from Kelly Associates. The plug-in clock and message generator board allow easy building and a great deal of flexibility in housing the circuitry. The photographs show one packaging possibility used by K1ZPX in a complete control console for his RTTY station. The original circuit was developed with hand-wired boards and performed very well. Adequate bypassing from Vcc to ground is one of the secrets in getting TTL logic to work. A .01 uF disk ceramic for each 4 TTL circuits is adequate.

Included in K1ZPX's control box is a Hoff designed UT-4, power supplies for both units and switching circuits to select up to 3 transmitters and receivers. There is one interconnecting cable to the ST-6 that contains all the control signals required for both circuits.

Testing

First, get the digital clock working. This is easy since there is very little circuitry for this unit. The message generator board is not required for this step. Be sure the voltages are proper to the clock. Check out each switch setting to be able to set the time and date and watch it operate. The seconds should reset to "00" when the time is selected for setting. When the setting switch is placed in the run position, this counter should begin counting. When the count reaches 8, the chip should switch to date mode. After two seconds in this mode, back comes the time and the seconds counter should now begin counting at 10. Just one word of caution, the clock chip is very sensitive to static discharges. Don't solder on the circuit board or its interconnections with the chip in the circuit. Take it out and place it in its shipping pad to act as a discharge preventer. Also use a socket for the chip.

After the clock is working, remove the clock board from its socket and insert the message generator board into its socket. With power applied, check the output of the

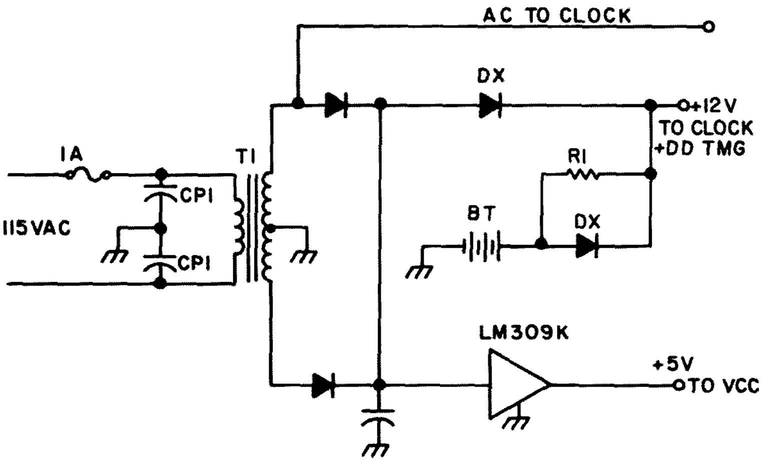

Fig. 9. Power supply, with back up power for clock.

U12 clock and set its frequency at 91 Hz. A counter is best for this, but a scope will do using 60 Hz as a reference signal. Place the CW memory in its assigned location. This location will be consistent with the address "wired" into the address counter preload. The RTTY memory must be plugged into the first position on the memory bank. Pressing the CW start switch should force the address wired into the preload into the address counters U6 and U7. The counter should advance and the CW message should appear at the output pin. When the message is complete, the reset character, bits 3, 4, 5 and 6 at the "1" level will reset the CW latch (U17 C and D) off.

Circuit board for the DDTMG. The pot on the upper right sets the basic timing for all circuit operations. Eight sets of molex pins are used to make the memories plugable across the bottom of the circuit card.

When this circuit is working, it is time to try the RTTY message. With the digital clock removed, the RTTY message should print with blanks in the place of the time and date digits. When the end of the TTY message is reached, the TTY reset character will force the CW latch on and the CW message will be sent.

When the above circuits are checked out, it is time to check out the time/date de-multiplexer. First, using jumper wires, tie the clock digit lines to plus 12 volts. Then select the following clock segment lines and tie them to plus 12 volts. The digit shown should appear:

Seg A	Seg B	Seg E	Seg F	Seg G	Number
1	1	1	1	0	0
0	1	0	0	0	1
1	1	1	0	1	2
1	1	0	0	1	3
0	1	0	1	1	4
1	0	0	1	1	5
1	0	1	1	1	6
1	1	0	0	0	7
1	1	1	1	1	8
1	1	0	1	1	9

When all of these tests are completed, shut down power and plug in the clock. When power is first applied, the clock will indicate all 8s. Try the message generator in RTTY mode and see that the 8s print properly. When they do, go ahead and set the correct time and date in the clock. Pressing the RTTY start switch should give you that desired message we all wanted when we started the project. Out will come the time and date, providing the programming of the chip was correct.

This circuit has been operating for about 8 months now without a circuit failure. It has really been handy to use with the relay and WRU system at W1HAB. With an external programmer the unit becomes a very versatile unit to send up to 8 different messages at the touch of a button.

Special thanks are due to WA1DQL, who provided the motivation to do the design, to K1ZPX, who checked out the prototype, and also to K2USG, for the photographic work. ■

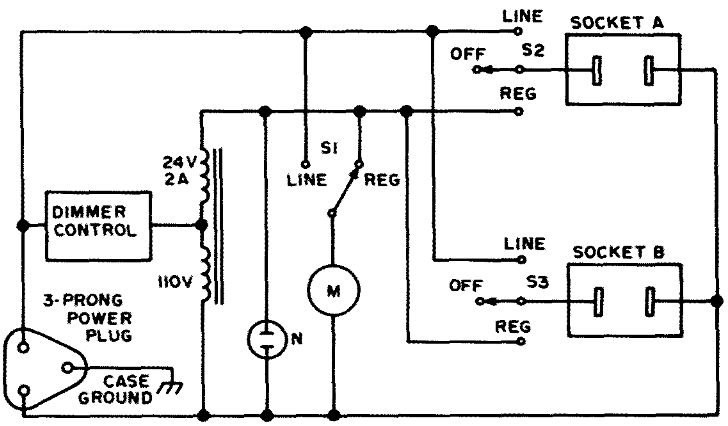
The Solder Master



For contemporary assembly projects I use popular, screw-in element and tip soldering irons which, with tweezers and magnifying lenses, are tools of the micro-component age. Frequently I use two irons at the same time – a 50 Watt heavy duty for large joints and a tiny tiplet for compacted PC boards. Frustration is maintaining both irons at proper temperature. The big element, left idle for any time, toasts its solder tinning and threatens self-destruction, requiring unplugging. The tiplet dissipates heat too fast for more than one connection, involving impatient recovery time.

At the aerospace plant where I do my thing, our young ladies at each assembly

station have neat, solid state soldering iron control units with voltmeters for adjusting desired element temperature. Just what I needed. I checked the price of these commercial units with our purchasing department. Following a brief respite in the first aid station, I regained my composure and applied some ham thinking for a better solution.

The el cheapo answer was the commonly available "light dimmer," rated at 600 Watts and solid state at that. Lucky I had one in the junk box that would tame the heavy duty iron. But while lowering the voltage, why not also boost it briefly to help the tiplet along? A 24 V, 2 Amp filament transformer solved this.

The photos show how the major items were squeezed into a 5" x 3" x 3" aluminum utility box with two outlet sockets, in the initial version. An available miniature meter (yes, the dial does say "RF") was pressed into service, modified with bridge rectifier and series resistor to read zero to 1.0, for reference. This worked great, but had some inadequacies such as how to control the irons separately, which was soon taken care of with a few more parts.

The schematic gives the final story, which included adding three small toggle switches not apparent in the photos. I also splurged on a new meter of the same size, reading 0-150 V ac. The transformer primary and secondary windings were connected in series to make an auto-transformer, having checked proper polarity connection so that with 110 V ac across the primary, 130 V ac was measured across the combined windings. The "dimmer" control adjusts line voltage to the primary so that regulated output to the sockets can be varied from 0 to 130 V ac with the front panel knob. S2 and S3, miniature single pole, triple throw (center position OFF) toggle switches, were installed right below the meter, in line with their respective sockets. These allow either socket to be switched to regulated or line voltage, or "off," independently. S1 was rather gilding the lily in switching the meter to read regulated supply, or double as a line voltage monitor. This miniature SPST switch was located immediately to the left of the meter. Due to the pulsating waveform output from the dimmer control, voltmeter readings are not really accurate rms, but close enough for reference adjustment.

Now I keep the larger iron happy idling at 70 V, while using the small one switched to "line" – or switch it off temporarily, while boosting voltage to the tiplet to solder multiple joints. Start up time is reduced by briefly applying full 130 volts, but boost voltage (over 110 V) should be kept to the minimum to avoid premature element failure. And when the XYL sounds chow call, both irons can be left idling at approximately 60 V, for fast reheat upon return. The neon pilot light, being connected across the regulated voltage, extinguishes at about this control setting. If you set the control where the pilot is flickering, this is just right for keeping the irons warm.

Note I finally use a three wire power line input to provide ground to the metal case. This is not only a desirable safety feature, but also provides shielding for noise spikes emitted from the dimmer control. Should you use grounded tip irons, you will also want to substitute 3-prong outlet sockets rather than the 2-prong types.

You may also find some other handy applications for this voltage controller around the shack – but don't exceed the transformer wattage rating by plugging in the coffee pot. I had most of the parts on hand. If all parts are bought new – and dimmer controls which retail for around $5.00 can be found on sale for as low as $2.98 – the total cost even in this age of inflation should not exceed $15.00.

One last warning. The push switch built into the dimmer control serves to turn the regulated supply on and off. But, while plugged in, the unit will furnish voltage to the sockets when either S2 or S3 is switched to line. Inadvertently leaving the irons on is avoided by leaving S2 and S3 at center position OFF when not in use.

Anyway, shutting off the main bench safety switch, which controls all outlets, is double protection. You do have a main safety switch in your shack, don't you? ■

When the **XYL** sounds chow call, both irons can be left idling . . .

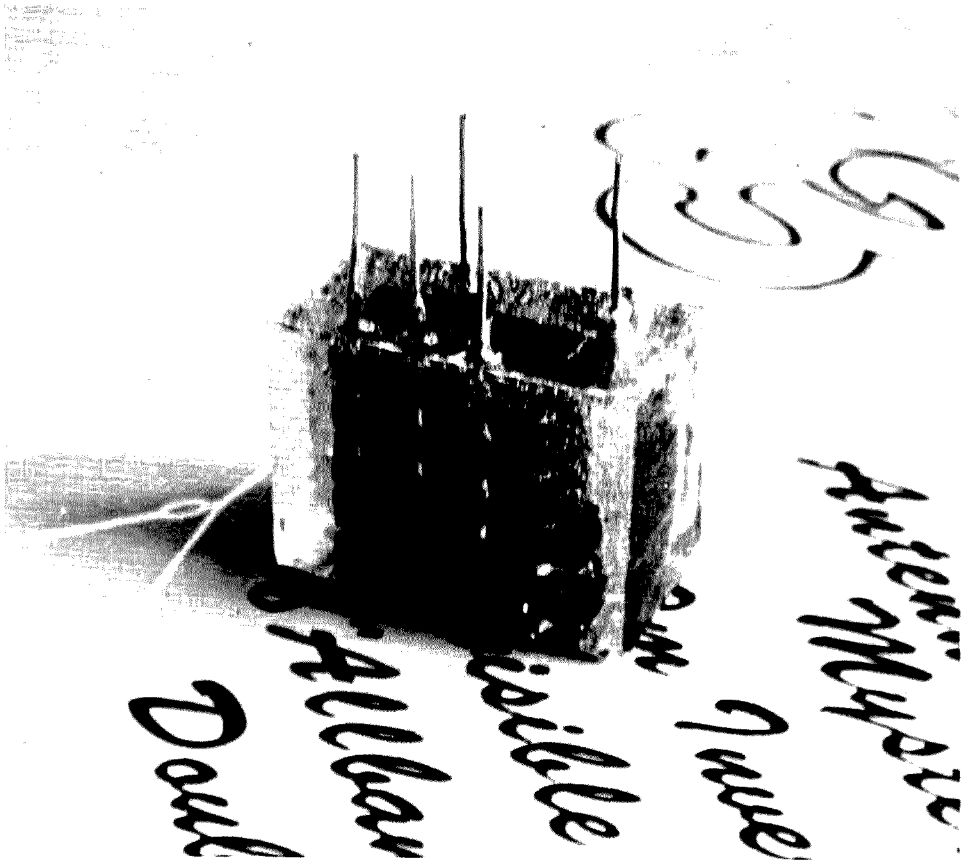
Stack Your ICs

by
Maj. Robt. M. Harkey (Ret.) W4CUG
1204 Dooley Drive
Charlotte NC 28212

As unlikely as it may seem, one disadvantage that the experimenter has when using and designing with integrated circuits is coping with redundancy. As an example, when designing/constructing a series of redundant circuits from ICs such as frequency dividers for the timebase of a counter, the layout of the circuit board becomes a formidable task. As far as I'm concerned, anything that can be done to simplify board layout is well worthwhile – and therein is the purpose of this article.

A very basic block diagram consisting of a divider circuit for counting down a 10 MHz crystal oscillator to 1 Hz is shown in Fig. 1. Since in this case there is no requirement for reset of the dividers, the circuit boils down to only four connections: plus 5 volts, ground, input and output. Now if you'll look at a typical counter circuit board, you'll realize the complex circuit board that it takes to achieve the desired four connections. So the question is: How do we integrate the integrated circuits? I think I have one solution.

Using the most common decade divider, the 7490, the solution is relatively simple: You just stack the ICs one on top of the other, make the necessary IC to IC connections, and pot the entire stack of ICs with a



And Pot 'Em

few external leads sticking out. Sounds good, doesn't it? But the "doubting Thomases" among you probably think there are a few catches – and there are. First and probably the greatest danger is the possibility of one of the 7490s becoming defective and thus ruining the usefulness of the entire stack. Based upon my experience, this is highly unlikely if care is taken with the supply voltages. The 5 volt supply should be well regulated and in no case should the supply voltage be reversed to the IC stack. Although I have gotten away with this a few times with individual ICs, the usual result is destruction of the IC. Another consideration is heat dissipation. The 7490s run relatively cool in normal operation, and so far I've experienced no difficulty with stacking and potting seven of them. The potting material obviously helps with the heat dissipation, but to be absolutely sure, you could include a heat sink or fins when potting the stack. The last consideration for the stacking process is how to make the many interconnections to seven 7490s stacked in a group which is no more than 1¼ inches high. Very simple task with the 7490. Referring to the 7490 pin connections in Table 1, you will note that pins 2, 4, 6, 8, 9 and 13 require no interconnections. Also, the following pins can be directly interconnected between all ICs and constitute a ground connection for the entire stack: pins 3, 7 and 10. Thus the only indirect IC to IC connection that must be made is between pins 1 and 12 to connect the inputs and outputs together. In addition, pins 11 and 14 must be connected on each IC to tie the divide by 2 and divide by 5 sections together. (This method provides a symmetrical output from each IC.) So, if you're still with me, let's stack two 7490s step by step; stacking any number can then be accomplished by repeatedly following these steps.

On each IC to be stacked, bend pins 2, 4, 6, 8, 9 and 13 straight out and cut them off flush. This action deletes unneeded pins and permits more room for other connections. Bend pins 11 and 14 in and flush up against the bottom of the IC body. Using a small piece of hookup wire, connect pins 11 and 14 together and carefully solder the connections. Now bend pins 1 and 12 straight out and cut off the tip ends of the pins. At this point, you should have 2 pins bent under the IC and connected (11 and 14), 2 pins bent out from the IC (1 and 12), 6 pins cut off (2, 4, 6, 8, 9 and 13), and 4 pins remaining in their original position (3, 5, 7 and 10). Now stack IC2 on top of IC1. On IC2, pins 3, 5, 7 and 10 should slide down smoothly over these same pins on IC1. Solder (carefully) pin 3 on IC2 to pin 3 on IC1 and do the same for pins 5, 7 and 10. Assuming now that the bottom IC1 is to be the input divider, use a small piece of hookup wire to connect pin 12 on IC1 to pin 1 on IC2. Using the foregoing procedures, continue to stack IC3 on top of IC2, IC4 on top of IC3, etc., until you have the desired number of dividers connected together. After you've finished the last IC, connect pins 3, 7 and 10 together with hookup wire. This connection is the ground point for the entire stack. Recheck the stack for shorted pins, solder bridges, poor solder connections, etc. Extend pin connections out the side or

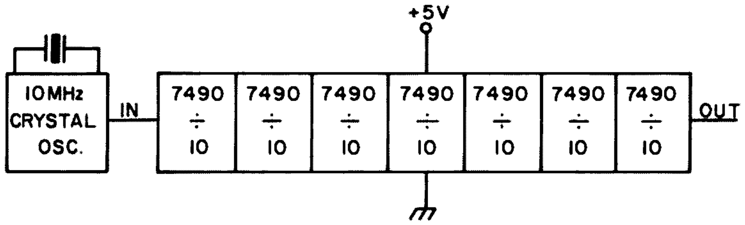


Fig. 1. Typical gate generation circuit divider for a frequency counter. With no reset requirements, only four connections are required to the decade divider circuit – in, out, +5 volt and ground. Note: For a 1 Hz count gate one additional divide by 2 stage is required.

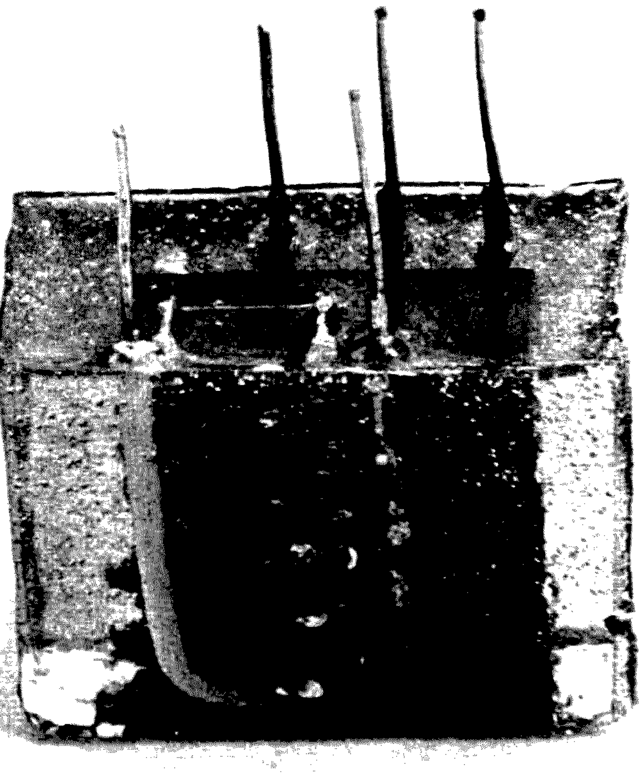
Pin 1 – Divide by 5 input	8 – BCD output "C"
2 – "0" reset	9 – BCD output "B"
3 – "0" reset	10 – Ground
4 – No connection	11 – Divide by 5 output (BCD "D")
5 – +5 volt	12 – Divide by 2 output (BCD "A")
6 – "9" reset	13 – No connection
7 – "9" reset	14 – Divide by 2 input

Table 1. Pin connections for a 7490 decade divider. Note that the "0" and "9" reset functions have duplicate pins and only one pin is required to achieve a reset. Also, for countdown circuits, the BCD "C" and "B" pins are not required.

bottom of the stack using small pieces of solid hookup wire. As many connections can be made as you want, up to 16 (for a standard 16 pin DIP socket). In my case, I brought out the input (pin 1 of IC1), plus 5 volt line (pin 5 of all ICs), ground (pins 3, 7 and 10 of all ICs) and the outputs (pin 12 of IC5 and pin 12 of IC4). Two outputs were brought out in case I wanted to change the clock frequency. After you've made the pin connections, form them to fit into an IC socket, cut them off about one inch below the stack and plug them into a socket to hold their shape during the potting procedure. Now, and most important, make a sketch of the base diagram of your stack! Connect the stack to a square wave oscillator and check operation of the entire chain. After satisfactory checkout, place the stack upside down in some convenient, small container which has been lined with plastic sheet, tape or similar material. Level the container and pour it full of a potting material. I used a two part epoxy for this purpose and found that it works well. After the potting material has set up thoroughly, remove the outer container with a knife and clean up the exterior of your potted IC stack. The pins can then be trimmed to a convenient length and you're ready to plug in your integrated integrated circuit into a much simplified circuit board. My stack is 1" x 1" x 1¼" and occupies a very small space on the circuit board.

This sounds like a rather lengthy process, but after stacking one set of ICs, it becomes very easy and quick. I'm sure the IC manufacturers have comparable circuitry in one IC now but the price is probably high. With the price of 7490s now in the 75¢ area on the surplus market, this is a very inexpensive method of making circuit boards smaller and simpler. ■



This is the completed potting job. The potting material is clear and internal connections between the ICs can be seen. The pins are ready for trimming to final size prior to insertion into an IC socket or printed circuit board.

Build This $5 Timer

by
P. C. Walton VE3FEZ
421 Lodor Street
Ancaster, Ontario, Canada

Do you have a TV in your bedroom? Have you ever fallen asleep and left it on? Or even worse just find yourself falling asleep and remember that you have to get up and turn it off? This versatile timer will turn the TV off from periods of three minutes after you have gone to sleep to periods up to about one hour. You can build this timer in one evening for a total cost of about $5 even if you have to buy all new components. The circuit I used, shown in Fig. 1, takes advantage of a new integrated circuit from the Signetics Company called the NE555. The NE555 is a very stable monolithic timing circuit in the form of an 8-pin dual in line package. It is currently selling for $1 from most suppliers.

The NE555 is capable of time delays from a few microseconds up to several hours. These delay periods are dependent on an external RC network consisting of one resistor and capacitor.

Very basically the IC is made up of a voltage comparator circuit, one leg of which is connected to a reference voltage which in our case is the power supply output voltage. The other leg of the voltage comparator is connected to the external RC network. When the capacitor has charged to a voltage equal to the reference voltage the comparator will toggle a flip flop connected to its output. The ON level of this flip flop is used to turn on a driver circuit which picks up our time delay relay. This is a very basic description of a fairly complex IC. If you require a better explanation of the internal workings you can obtain one by writing to the Signetics people and requesting a data sheet.

The relay I used was an IRC MR312C with a coil resistance of 212Ω. Almost any 12V relay will do the job as long as it does not draw more than 200mA from the output of the NE555 which is rated at 200mA. The RC network is a 100μF capacitor in series with a 5MHz linear pot and a 1MHz resistor. These values with the power supply that I used gave time delays of 3 minutes at the low resistance end of the pot and 58 minutes at the high resistance end.

You may have to experiment a little bit to get the exact time delay range that you require. This is due to possible differences in power supply voltage and components. You could even switch in different values of R and C with a rotary switch to give you several different time delay ranges. The power supply is just an old 6V filament transformer that was in the junk box and a full wave rectifier and filter capacitor. Parts layout is not at all critical and the whole unit can be kept very small. I built mine on a scrap piece of perfboard about 5.08W x 7.62cmL (2"W x 3"L). The completed circuit board is mounted in a standard minibox using a three wire power cord for safety. On the front of the box is just a standard 110V three wire receptacle, the pot for setting the time delay period and the pushbutton to start the timer. The time delay pot was calibrated using an ordinary clock and a lot of patience. ■

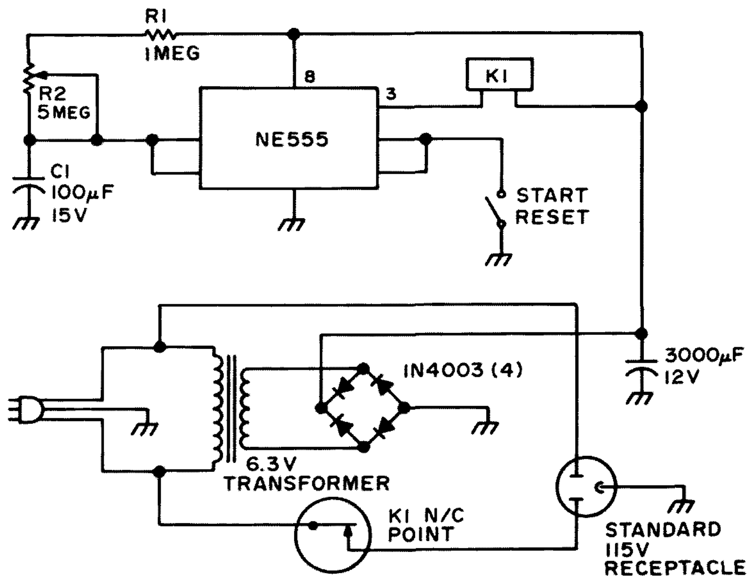


Fig. 1.

A $50 Self-Powered Counter

by
Jim Huffman WA7SCB
PO Box 357
Provo UT 84601

To you this may look like another construction article. "A pretty neat little counter," you'll say. "Think I'll build one." Little will you know how long it took me, and how much sweat is in one factor – cost. I love to get the cost on a project as low as possible through judicious shopping. It is my dream to offer all kinds of low-priced amateur gear . . . again! Some guys, like VHF Engineering, seem to be out to help the amateur by keeping the "amateur" in amateur radio. Others, however, look to me like they are out to soak the ham, right along with the CBer, consumer and anyone else who wants one of what they've got. I have written a bunch of articles for *73*, and all of them are on good inexpensive items that I think can put the "fun" back in amateurism. This article is one of my greatest achievements – the pinnacle of savings! I take great pride in accomplishing what I have done here. A 6-digit (that reads out to a full 8-digit capacity) counter, portable, hand-held, sensitive, rugged, LED readouts, requires no test equipment to build, and more, all for just a little over $50!

Costs are sliced down to an absolute minimum by cutting all the frills. For instance, many counters advertise no-flicker, or non-blinking readout. I am proud to announce that this one blinks, but you can only see it on the lowest reading scale, when you are reading signals to 1 Hz. The rest of the time the digits blink for 1 ms, and when was the last time you could see a 1 ms blink? Most hams will use the MHz and kHz scales most of the time anyway so the "blink" will be for 10 us and 1 ms respectively. And, when you are showing the XYL or neighbor your latest creation, show 'em on the Hz range so they will be impressed by the blinking, counting readouts!

While cutting out the non-blinking feature does save some money, the greatest saver is cutting out 3 of the 6 digits! I know, you are wondering how it is that we get a 6-digit counter with 3 of the digits missing. At current prices, dropping 3 unnecessary digits saves nearly $25. Even at TWS a 3 DCU costs $18. So if you can liberate an extra $18 for this project, you can have all 6 digits! But it is all the more fun to drop 3 digits, build the unit in half the width, and shift the readouts around to get a look at 8 digits of the incoming signal. Even in a 6-digit counter you have to shift the range switch around to get readout of say a 14.85 MHz signal to the nearest 1 Hz! With the Handi-Counter you have just one more shift to get the same capability with only 3 digits!

The basic "brains" for the counter come

from a kit available from TWS Labs. So order a digital dial kit from TWS Labs, PO Box 357, Provo UT 84601 for $45.95. When you order the digital dial, you get the same stuff you would get if you order the individual kit (a 3 DCU and a timebase), but you get a free ac power supply in addition. In fact, you can power your unit from this supply if you don't want to add nicads like in this version of the Handi-Counter. Or you can keep the power supply and have a good source of fairly well regulated 5 V dc for your workbench. The fact that the basic counter comes in kit form makes this project all the easier. All you need to do is make some very simple modifications to the kit, add the digit switching circuit and a couple of extra circuits on perfboard, and walla! Instant 3 x 6 digit counter!

Operation

Let's look at how you use the unit before you build it. Actually, the principle of operation is so simple that it is a wonder someone didn't think of it before (maybe someone did . . . better check my back issues of *QST*). You can see from the photo that there are several front panel controls. First is the on/off switch, simple enough function there. Second is the MHz/kHz selector (both these switches come with the kit); this one selects timebases, and does some decimal point selection. We could have labeled it Hz/kHz like its 6-digit brothers; it would only have required putting the decimal points in some other places that were not convenient (and cheap) with this kit.

The third switch, the one in the middle of the panel, we can call the "display selector" switch. This one comes from your corner Radio Shack and is p/n 275-405, a 4 PDT switch that currently is priced at 69¢. Other than the box and batteries, this is the only expenditure that is not available in a kit. You could have a complete counter that would only read to 100 Hz so far. You either add my famous circuits shown in the article, or buy another kit from TWS Labs for the 1 Hz capability.

Back to the 4 PDT switch. It is used to select which 3 digits of the 6 available digits are viewed at any one time. When you throw the switch to the left, you see the left most significant digits and to the right, you see the 3 right most significant. The decimal point jumps around every time to keep you thinking straight. Fig. 1 shows how it works. For an example, we used a forty meter signal that is actually 7,224,362 Hz. This is how the counter sees it: Note the placement of the decimal point; also note that in kHz left and MHz right, the readout is the same, but the decimal point is shifted. That is because, if you look at the original signal you can see

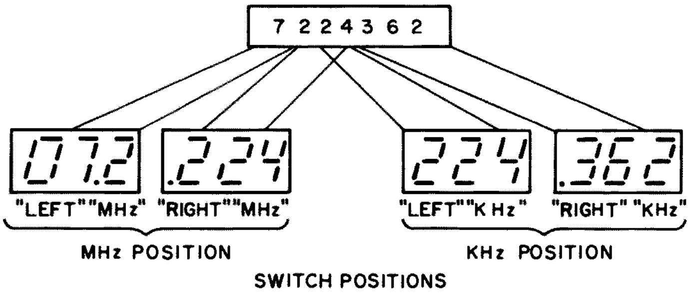

Fig. 1. Here is how the digital display in the Handi-Counter shows the eight complete digits in this forty meter signal. You simply move the digital display around and "look" at different portions of the signal at selected times.

that there are: 7.2 MHz, .224 MHz or 224 kHz (see, the readout means the same thing), and finally .362 kHz. That last 0.362 kHz is the same as 362 Hz, but would demand another timebase switch position, so we merely switch a decimal point and call it a fraction of a kHz.

Suppose you hook the sensitive input circuit of the counter to an oscillator you built the other day. You want a look at the output frequency of the oscillator. Maybe you see 21.8 on the MHz left setup; that means the oscillator is running at 21.8 MHz. If you were only interested in roughly knowing the MHz range of the oscillator, you would stop right there. If you wanted the kHz range you would leave the display left, and throw the timebase selector to kHz. That would give you a frequency check to the nearest kHz. Suppose you wanted further accuracy, or to know how much it

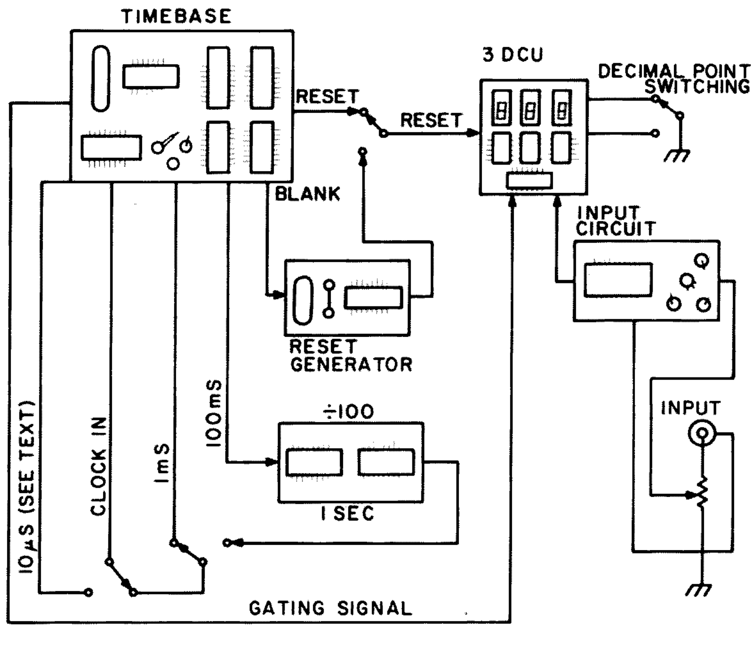

Fig. 2. This is the block diagram of the unit showing some of the switching that is accomplished with only two switches in the unit, a DPDT that comes with the timebase kit and an "added" 4 PDT.

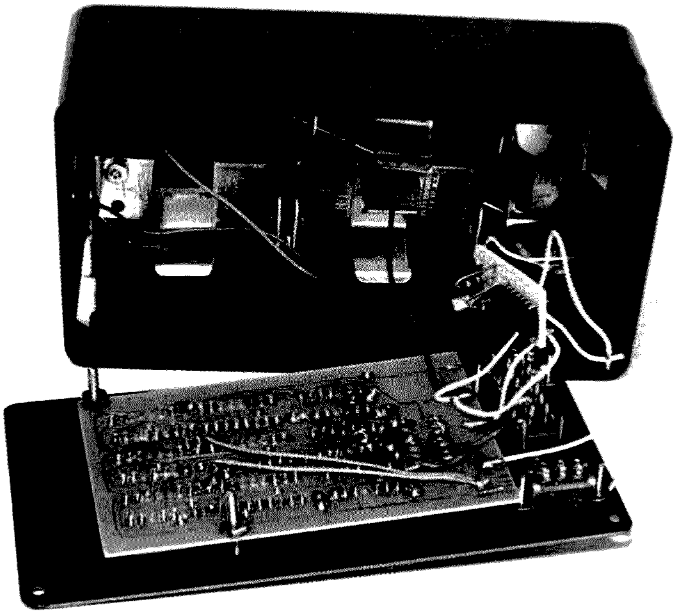
Building the counter is really not hard – collect all the parts, do the layout of the front panel, and finally, mount the pieces in the box . . .



The first step in putting the thing in the box is mounting the front panel. Note the input circuit mounted on the switch. Later, the wires were extended so the input circuit could be mounted in the cavity formed by the irregular battery mounting.

drifts; then flip to the right digit display (still in kHz) and read out in Hz. You can see the flexibility of the whole thing! It's unreal! You have 3 digits in a lot smaller package, for a lot less cost and you are reading a 21 MHz signal out to eight places! Oh, the miracle of electronics . . .

Fig. 2 is the block diagram of the counter and this will help you understand what is going on in there. The easiest process takes place in the kHz position. Here, the timebase selector and display selector switches choose to provide a one second (right) or a 1 ms (left) signal. This is high-accuracy stuff with the timebase being divided by a million to get the one second clock; any errors or drift in the timebase oscillator (already crystal-controlled) are divided by the million too. At the very beginning of the count time (1 sec or 1 ms), the timebase gives a reset pulse that starts the counter stages at 000. Then the counter merely counts the input pulses that occur during the selected time period. On the kHz left position, for example, the counter is cleared and enabled for one second. When counting a 60 Hz line input, the counter would start to flash (the part that will impress the average observer) until the end of the counting cycle when it will sit there displaying .060 kHz, or 60 Hz.

When the display selector switch is pushed left, we apply a 1 ms gating signal to the counters and count the events that occur in 1 ms, or in other words, we count kHz. A 30 kHz signal will show up as 030. Note that there is no decimal point; there is no need, as the timebase selector is in the kHz position so it reads out as a whole number, not a decimal fraction. From the block diagram, when one switches to the MHz range, the clock now comes from 1 ms and 10 us. The 10 us clock is fed to the counter circuits in the "MHz left" position and merely allows the counter stages to count for 10 us. On this scale, the chance for error from the 1 MHz crystal is greater and the fact that the timebase is crystal-controlled becomes the greatest asset. At the 10 us

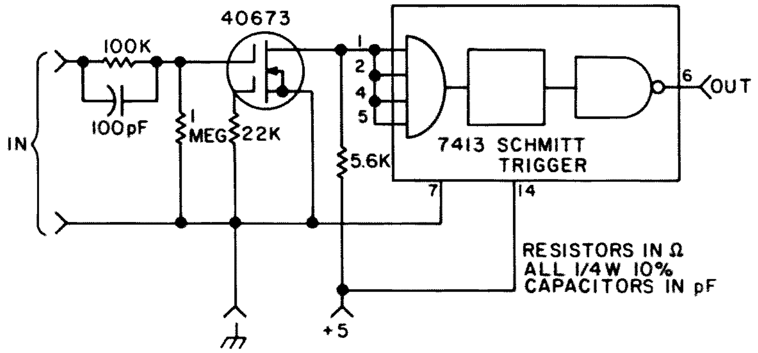


Fig. 3. Schematic diagram of the input circuit used with the Handi-Counter.

point the clock signal is only divided by ten. With 10 us gating the counter can count up to 99.9 MHz; in real life the limit is imposed by the fact that the counter circuits will only operate to 30-40 MHz without a prescaler. Since most prescalers divide the display by ten, you will display MHz on all three digits, so the decimal point can be left out.

It is probably a good idea to explain why there is a different reset circuit than the one with the kit. The reset circuit with the kit is designed to give high accuracy with fast input signals and operate at a 10 ms and 1 ms gating output. While the kit's reset is more accurate than the "extra one" built for the Handi-Counter, it causes some problems while running at slow speeds. The reset actually resets a couple of clock pulses *before* the gating signal enables the counter. That works great at 1 ms and 10 ms and means that you are not depending on the characteristics of the input impedance of a gate and some resistors and capacitors for your reset pulse; the pulse is clock controlled. The trouble comes when the clock is one second. The strobe circuit causes the counter to sample the input signal every second and a half or so and you can extend it to a few seconds by increasing the size of the timing capacitor in the unijunction oscillator circuit. Well, at one second clock speed, the counter resets to 000, waits a couple of clock pulses (seconds), then enables the counter stage and the stages count the input signal. After the one second counting period, it is time

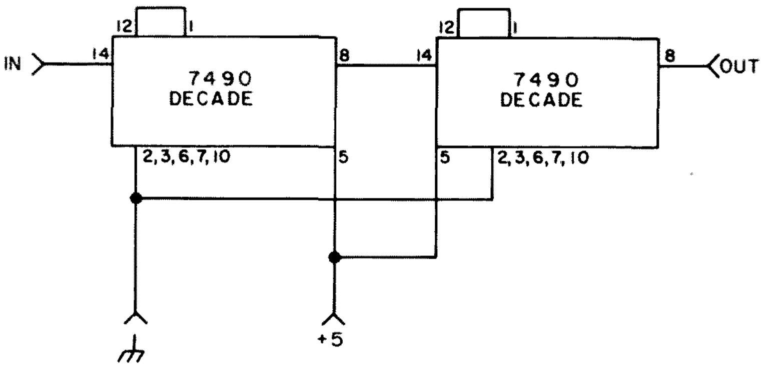

Fig. 4. Schematic diagram of the divide by 100, one second extender circuit. This circuit allows the counter to look at signals in the hundreds of cycles range and provides readout to 1 Hz.

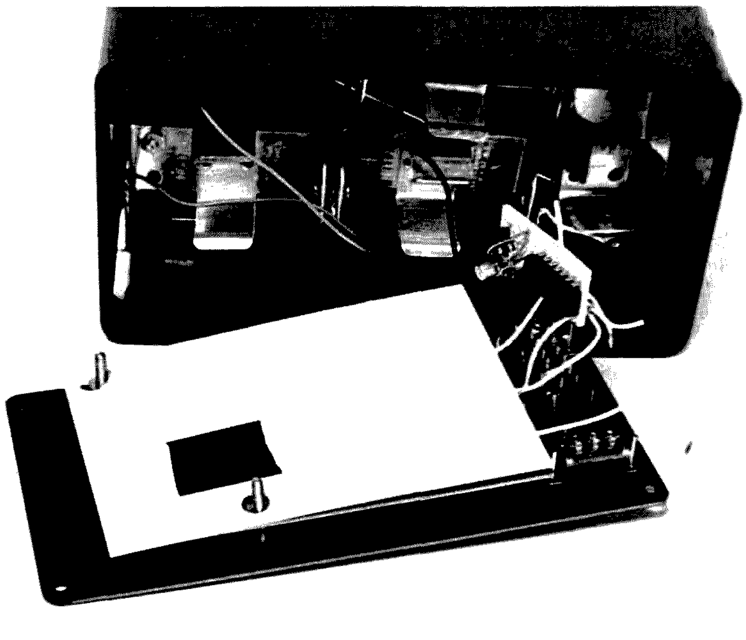
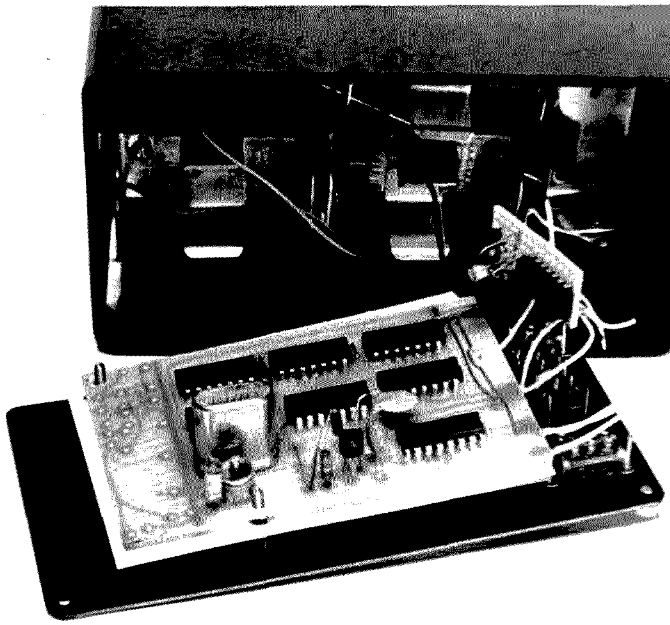
for another sample and the display resets again. The result is you don't have the display lit long enough with the number to even read it. You may choose to merely extend the sample time by putting more capacitance in parallel with the timing capacitor (33 uF) in the unijunction circuit that comes with the kit, or you may use the reset circuit shown here.

The reset circuit built for the Handi-Counter works like this: When the enable signal goes active to allow the counter to count the input signal, a very fast RC differentiating network creates a narrow spike that resets the stages. You can see that since this spike occurs because of the enable signal, it actually resets the circuits when they are supposed to be counting. This is no real problem at slow speeds, but at higher



This photo shows the details of the piece of 3" x 5" file card, reinforced as mentioned in the text. This card insulates the timebase and the 3 DCU.



This shows how the timebase board is mounted. Note that there are no components at the top of the board. The top of the board is reserved for the power supply parts which are not used with the battery supply.

speeds, if the reset pulse is very wide, it can knock off a pulse or two and give an inaccurate reading. For the 10 us signal knocking a few pulses off can throw the MHz readout way off. In most counters that use this method, they merely adjust the clock signal so that the counters are enabled a little longer, but few of those counters use a gating signal of only 10 us, so that's why we have the two reset signals.

The counter input amplifier shown is pretty sensitive. Although I never measured the sensitivity, it works well just picking rf up with a little wire antenna. Its major problem is that you can blow the FET pretty easily. So be careful about input signals.

To calibrate the counter you can use a known accurate signal, or beat the oscillator against WWV. I prefer the first method because there are some pretty whacky beat notes because of the frequency division and some are only a hundred Hz away from the main signal.

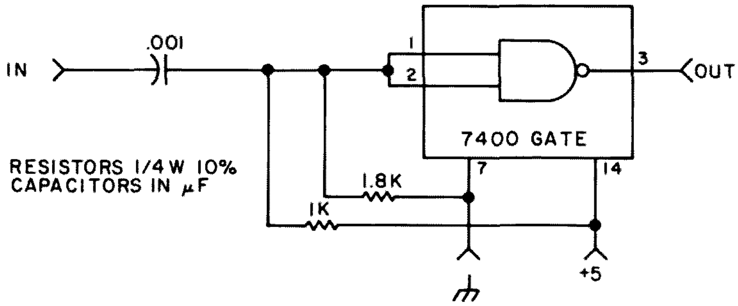


Fig. 5. Reset generator schematic. This added circuit provides a reset for the counter in the low speed (1 Hz) readout position.

Construction

Building the counter is really not hard. Obviously, the first step is to collect all the parts, then do the layout of the front panel of the case, and finally, mount the pieces in the box. You can use any box for your counter; I wanted the hand-held size and battery power so I obtained a 2¼" x 3" x 6" black box from a local supplier and tried almost in vain to paint on some kind of trim. If you can obtain one of these, get one with an aluminum front panel – it is easier to paint, cut and work, than the phenolic one that I bought. From all the photos, you can see how and where I put the switches. The key to switch mounting is to keep the switches out of the way of the 3 DCU and timebase circuit boards. These photos do not show the input jack and the sensitivity control; I mounted them on top of the case later. You will probably want a jack for charging your nicads without removing the cover from the box. If you decide to make your unit non-battery-powered, you will still have a lot of room in a box this size because all the power supply components mount on the top of the timebase PC board, and the transformer is small enough to sit on the bottom of the case.

Mounting Batteries

The bottom of my box wasn't flat; it had

some design raised in there, presumably to add strength. This was a problem in mounting the batteries and I ended up being able to get only one bolt through each holder and that only thumb tight. That only allows the batteries to stay in place, and offers very little strength against dropping, etc. You can see how the batteries are mounted from the photos. They are mounted to leave a "cavity" so the crystal, which sticks into the case pretty far, has room to keep from getting crushed. This cavity also makes a convenient place to put the three external circuit boards.

The battery mounting bolt leads stick out of the bottom of the case to mess up the effect of the little "feet" on the box. It is easy enough to glue flat grommets to the bottom, with the hole over the bolt heads for better feet than were on the box in the first place. Note: Later experiments showed that it is easier to buy a plastic 4-C cell holder and use it. The holder mounts in a smaller space than the individual cell holders and there is plenty of room for the crystal and external circuits. An added benefit is that the holder is cheaper than four of the individual units.

Building the Circuits

It is easy to build the kits; all the instructions are included. Trim leads very close to the PC boards. While the kit instructions do not stress this, we are going to mount the PC boards back-to-back under some pressure and we don't want any extra long or sharp leads sticking out of the boards. I recommend you even trim the leads on the crystal.They don't mention it in the kit, but it helps in sandwiching the boards closer together. Also take care in running the external wires on the board. They should be laid out so that they do not cross any pins or leads on the back of the board. Under pressure, these can puncture the insulation on the wires and cause a short. If you are using a different physical approach and have plenty of depth in your box, use the mounting method described with the kits and you eliminate many of the aforementioned problems.

Building the Input Circuit

The input circuit is built on a phenolic board, although you can make a tiny PC board for it if you want. Or, if space is at a premium, you can get the timebase extender board that comes in kit form from TWS; it is roughly 2" x 3" and has all three of the external circuits right on the one board. You can see the layout of the input circuit in the photos that show the inside of the box. In the photos it was mounted near the input

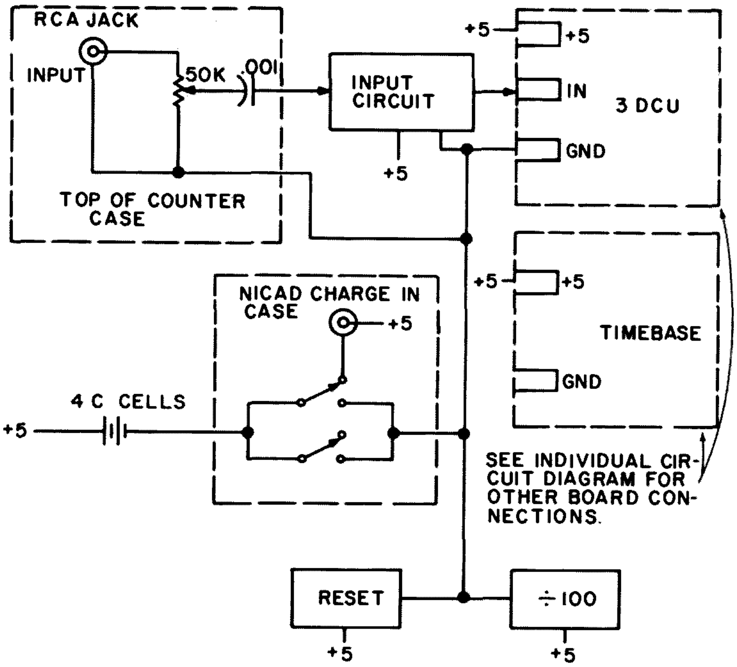

Fig. 6. Major power hookups and input circuit hookup. Note the nicad charging circuit. With a power supply (charger) plugged in, the nicads will charge when the unit is off. You may wish to allow them to charge at all times. If you use the power supply supplied with TWS's kit, you turn the unit on and off by cutting the ac from the ac cord to the transformer input.

selector switch, while in the final version, longer wires were added and it fit in the cavity formed by the batteries, and near the input level control and input jack. Make sure your wires are long enough to put it where you need it. There is enough hookup wire with the kit for most installations. After the circuit is built, put some tape on the bottom of the board so the circuit will not touch the battery holders or the other circuits that are stuffed along with it in the battery cavity. Fig. 3 is the schematic of the input circuit.

Divide by 100, Extender Circuit

The 10 ms clock from the kit drives this

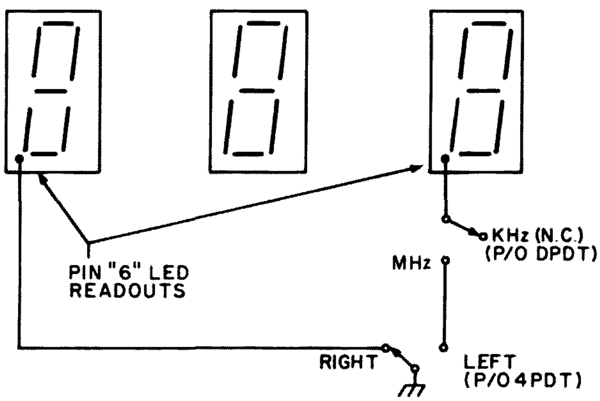

Fig. 7. Decimal point wiring diagram.

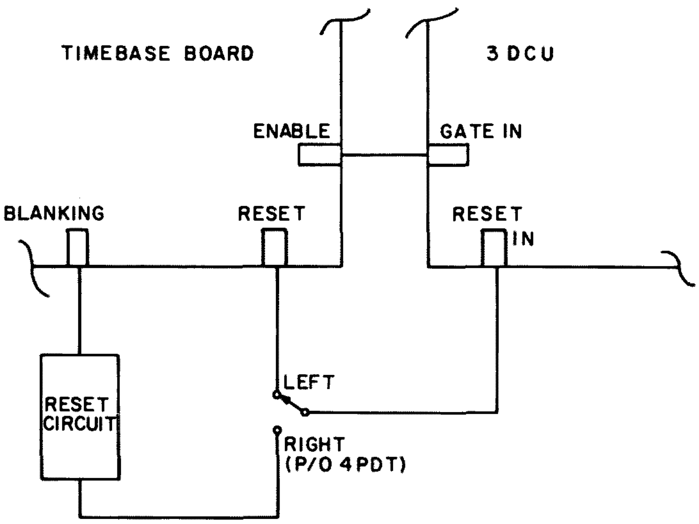

Fig. 8. Reset circuit hookup to the timebase and 3 DCU boards.

circuit shown in Fig. 4. The output of the divide by 100 circuit is one second clock used in the timebase generator to make the one second enable signal for the counter. The circuit is very simple, and consists only of two decade dividers in series. There is a photo of the perfboard layout for your reference.

Reset Generator

The reset generator is very simple; it consists of the RC network and a 7400 gate used as an inverter. Fig. 5 is the schematic of the circuit. The output of the gate is a normal logic 0. When the sample signal comes along (actually the inverse of the signal called the "blanking" signal with the kit), it causes a positive pulse output and resets the counter stages. Because of the nature of this reset, as mentioned before, it is best not to use it (use "kHz left") when looking at very fast signals. On slower signals, there will be no difference in reading between this and the "MHz right" readings.

Interconnecting the Circuits

Fig. 6 shows the major interconnections and the hookup of the input circuit. First mount the 3 DCU counting and display unit on the front panel as shown in the photo, then run the power and interconnections as given in Fig. 6. Run 1 inch wires from the terminals on the 3 DCU card; these will connect later to the switch and the timebase board.Run the decimal point wiring to the switches on the front panel as shown in Fig. 7.

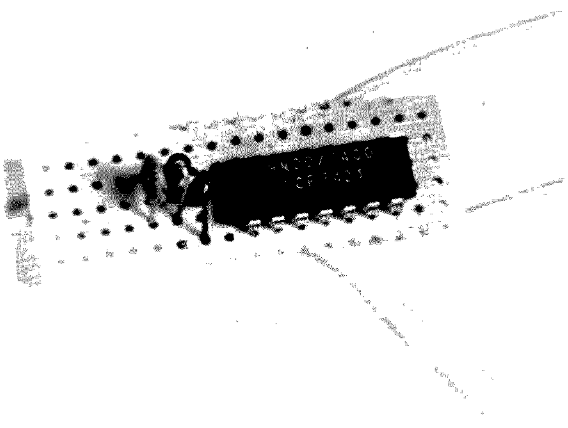
Fig. 8 shows how to connect the reset circuit to the timebase and 3 DCU boards. Fig. 9 shows the hookup for the interconnecting wiring that does the timebase switching, including the divide by 100 circuit.

When the wiring is completed, put an insulating card (a piece of 3" x 5" file card works great) between the 3 DCU and the timebase card as shown in the photos. First mount the whole thing up and tighten down the mounting bolts. Then take the thing apart again and inspect the piece of card for punctures where a wire from the circuit board was too long or too sharp. Trim the faulty wires or pins, reinforce the card with a black electrical tape strip around the puncture (if any), add another layer of insulating card, and remount the boards.

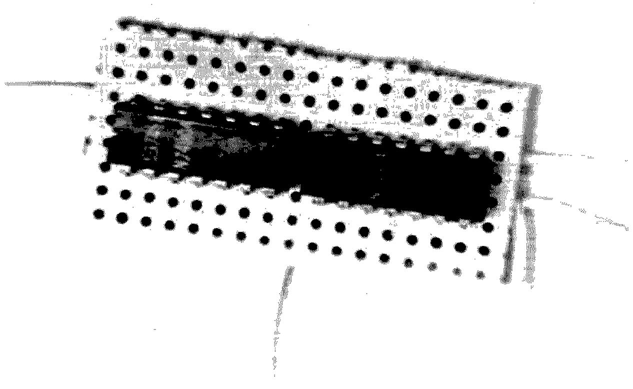
Put in the batteries, drop the input circuit, divide by 100 and the reset circuit boards in the cavity. Oh, and don't forget to install the input jack and pot. Wire the power connections to the batteries, and let 'er rip! The displays should light.

Checkout

When power is applied, the readouts may show any number reading at all. This is



This is the perf board-mounted reset circuit.



The divide by 100 circuit — it provides a one second clock for the Handi-Counter.

normal. After a second or two, and the oscillator is running and all the circuits "settle," the random numbers should clear. The display should flash "000." Now you are ready to use your counter and look for all manner of signal around the shack. Make sure the thing resets in all switch positions and you can tell if your new reset circuit is working okay.

Points to Remember

The unit will only run for a couple of hours from fully charged nicads, so don't leave it sitting around "power on" unless you are using it. The crystal oscillator is extremely stable and will work with little or no warm-up so don't worry about leaving the power on. Build a nicad charger[1,2] and keep the nicads fresh. Some will want a trickle charger that will always keep the unit "ready to go." You may want to build up the power supply external to the unit, let it trickle the nicads (there is 8 V unregulated in there), and use it for operating around the shack. You can also use cigarette lighter power by using a suitable dropping resistor. For that purpose, it is possible to use the regulator circuit and either positive or negative ground 12 volts. Instructions for mobiling come with the kit. Your resistor value will be different because of the extra current and IR drop caused by the added circuits.

This is one of the handiest pieces of test gear I have. And it cost very little, is very "state of the art" and requires no test equipment to build. I hope you enjoy building and using the Handi-Counter with its 3 x 6 digits and eight digit capability. ■

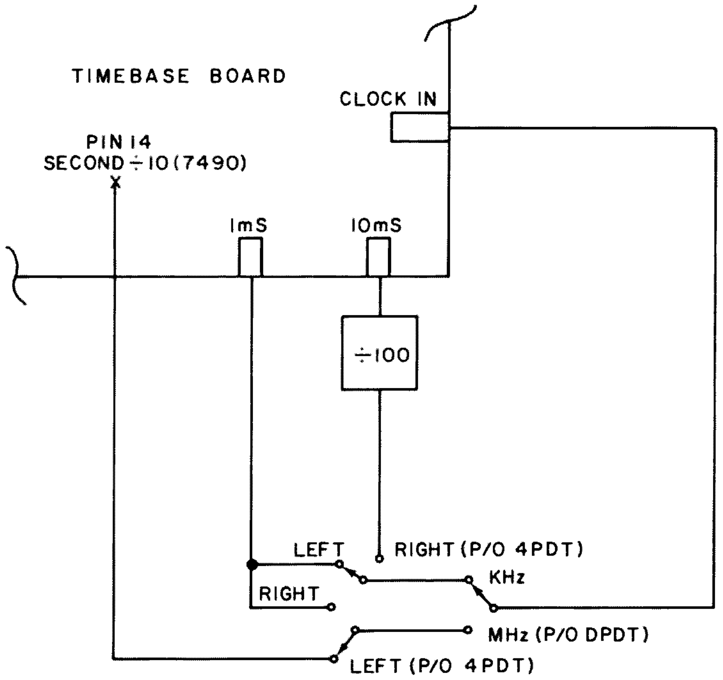


Fig. 9. Timebase switching diagram. Note that 1 ms is used on both MHz right and kHz left. The difference is the decimal point, and the source of reset pulse. (See other figures for details.)

Here is how the board is mounted on the front panel. Just snug the nuts on the mounting bolts down enough to hold the 3 DCU board in place and let the front of the readouts and ICs hold the pressure against the front panel.

How to Become a Troubleshooting Wizard

by
Joseph J. Carr K4IPV
225 North Glebe Road
Arlington VA 22203

In times past just about every amateur acquired, if only out of sheer necessity, some degree of troubleshooting acumen. Of course, it might be argued that rigs of those bygone days were a lot less sophisticated than rigs of today. Is that single fact really good reason for the seeming decline in general amateur troubleshooting ability? I think not. It is contended here that anyone with a knowledge of theory deep enough to pass the General class license examination can make a reasonably good attempt at troubleshooting. Of course, years of experience are needed to make a commercial troubleshooter but we are only concerned with maintaining the usual ham's station equipment and not how many high technology transmitters or receivers he can fix per day or week.

Crux of the Problem

Lack of familiarity and zero technique are two reasons why, to many, troubleshooting is troublesome. Consider a case in point. I have a friend who bought a "near-new" condition Novice CW transmitter for a song ($5) because the now-General former owner found out (after the new license arrived) that it wouldn't work on 20 meters. He even knew what the main symptom showed – no grid drive to the final on 20 meters. All other bands worked fine. My buddy, mind you, was not an experienced troubleshooter at that time. He was merely a thoughtful teenaged amateur. He reasoned that a loss of drive on any single band in a standard simple MOPA transmitter had to be either an open coil (on that band) or some defect in the band switch. In this case the wire on the band switch that went to the 20 meter tap on the grid tank coil was not soldered properly! This little story points out one main thing that will allow successful troubleshooting: Think out the problem ahead of time with schematic in hand, to ascertain all possible causes.

Test Equipment Needed

After working in a lot of service shops, I have grown weary of the fellows who use the excuse that they could "fix it themselves if only they had the equipment." While a bench loaded with expensive laboratory grade test equipment is desirable, it is not strictly necessary for most troubleshooting. Sure, if you were in the business of providing electronic service for a profit, it would be a justified purchase because of the time savings on each job. The average amateur, though, only wants to get back on the air without having to wait weeks for a repair shop's turnaround time to elapse.

What constitutes "necessary" equipment? Consider, first, that the most valuable and

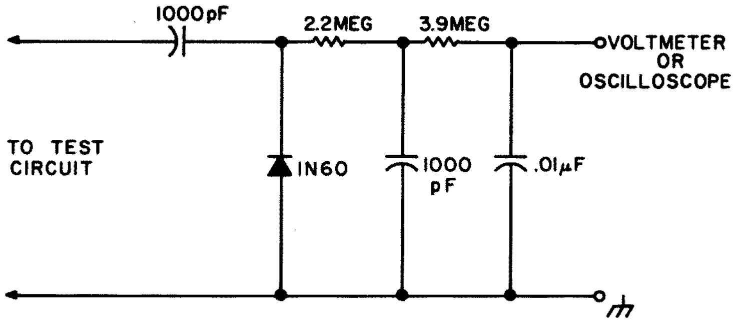

Fig. 1. Schematic of an rf demodulator probe for voltmeter or oscilloscope.

versatile piece of "test equipment" is already in your possession: your head! The mind can only function, however, when given a data input concerning the problem to be solved. For this we need our learned observations about the performance of the rig vis-à-vis the defect and some basic measurements, many of which can be taken with low cost or even simple home brew instruments.

Most basic in the troubleshooter's arsenal of instruments is some sort of multimeter. I prefer the traditional Volt-Ohm-Milliammeter (VOM) over the Vacuum Tube Voltmeter (VTVM) in those cases where money or other considerations dictate that only one instrument be purchased. It is wise to purchase an instrument with a sensitivity of at least 20,000 Ohms/volt (higher if possible). There are at least three reasons for this preference: portability, existence of a current range and insensitivity to rf fields. Many of the modern FET voltmeters fill the bill in the first two requirements (often better than the classic VOM) but most sadly fail in the third: They will read in error around rf fields such as exist in your transmitter.

The classic VOM will have ac and dc voltage scales, at least one current range (usually more) and at least one resistance

Years of experience are needed to make a commercial troubleshooter, but we are only concerned with maintaining the usual ham's station equipment . . .

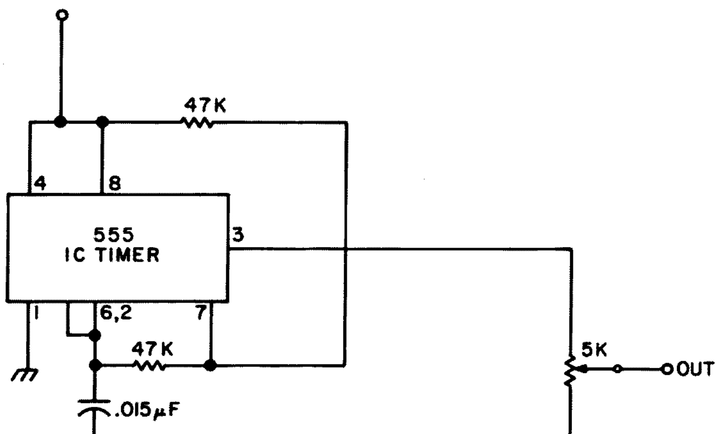

Fig. 2. 1000 Hertz square wave generator produces harmonics useful for signal tracing from audio to several MHz.

range. As is usual, the more you can pay for a VOM the more features and ranges you can expect. You can extend the dc voltage scale of most instruments well into the kilovolt range by the use of an external high voltage probe of the type which has a built-in divider network. It is also possible to get at least a relative rf level indication through the use of a demodulator probe such as that shown in Fig. 1. Most manufacturers offering such probes claim operation well into VHF.

The VOM is one of those "every ham should have . . ." instruments. Another in that category is the dip oscillator called "grid-", "base-", "gate-" or "tunnel-dipper" depending upon design. These instruments have an incredibly varied range of applications around a ham shack. They can be used to find the resonant points in tuned circuits, antennas and so forth. They can also be pressed into service as an absorption wavemeter, oscillating detector or impromptu signal generator. Best of all, they are simple to build and are low cost regardless of whether obtained in kit form or built from scratch.

One main thing that will allow successful troubleshooting: Think out the problem ahead of time with schematic in hand, to ascertain all possible causes . . .

In many troubleshooting procedures it might prove desirable to use a controlled, locally generated substitute signal. These are best supplied by a signal generator. Of course, a lab-grade instrument is the preferred type. It must be noted that many high grade signal generators are available on the used and/or surplus markets. While it might be "nice" to own a fine signal source, a more modest instrument will suffice for fixing the rig. It is necessary to keep in mind that "troubleshooting" and "alignment" are different procedures and that the signal generator requirements are vastly different. Commercial servicers have little trouble justifying a kilobuck signal generator for alignment purposes. They need the superior short term stability and a high quality attenuator; you don't. A "service grade" signal generator will be a very useful tool in ham troubleshooting. These are not up to the lab grade types in performance but they can be had for less than a month's rent on the big gens!

A crude form of signal generator useful for troubleshooting is shown in Fig. 2. This is a square wave generator operating at about 1000 Hz. Such circuits are widely used in the service industry because they can help pin point a dead stage in moments. These "instruments" generate the fundamental square wave and a boat load of harmonics that can be used out to several MHz. In most amateur work this means that we can "quick check" the audio, i-f and rf (on 160 to *maybe* 40 meters).

Your crystal calibrator may also suffice as a troubleshooting signal generator. In Fig. 3, we have a circuit that can be home brewed from low cost TTL digital ICs. Although the possible choices of output frequency are limited in this case you can obtain almost any frequency by correct choice of oscillator crystal and/or division ratio. If zeroed against a frequency standard such as WWV, this circuit can serve as an accurate method for frequency measurement. It can also be used as a regular signal generator or as a type of device shown in Fig. 2. In those latter applications it would be wise to provide an attenuator.

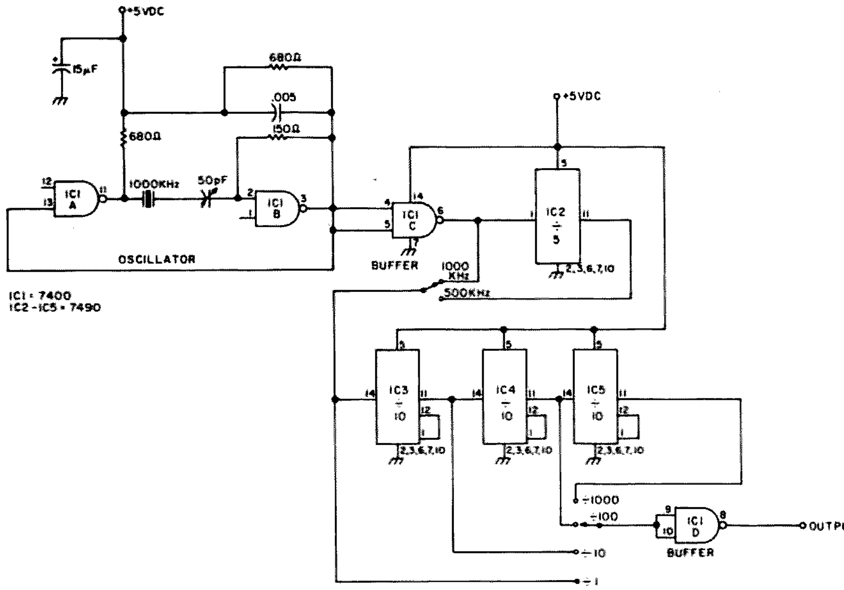

Fig. 3. Schematic of a TTL crystal calibrator.

If a smart troubleshooter were to be allowed only one instrument he would choose the oscilloscope. If triggered sweep and dual beam can be afforded, it would be very useful. Prices on 'scopes vary from $5/free to several kilobucks depending upon features, condition and vintage. I have seen many oscilloscopes, some quite nice, remain UNSOLD for lack of interest at hamfests and auctions!

Servicing typical ham transmitters requires several special instruments. Most of them are the sort which I feel ought to be in every ham shack. One item is the 50 Ohm dummy load. At a cost of only a few bucks you can have a dummy antenna which will absorb all the power you have a right to be dishing out to a real antenna. Only the utterly irresponsible would attempt to service a transmitter connected to a "live" antenna!

Rf wattmeters and relative field strength meters (Fig. 4) are also amongst the highly desirable. Although I prefer the wattmeter sort of instrument, make no mistake about it, the old fashioned swr bridge does have a lot of good mileage left.

No one seriously expects an amateur to be as well equipped with test instruments as a commercial or factory level shop. He should, however, attempt to obtain those considered "basic." For some of the others he might work through the local club to build a test gear collection of really nice pieces or arrange with certain locals to split the load by having each fellow buy certain instruments and then do a lot of "lendin'."

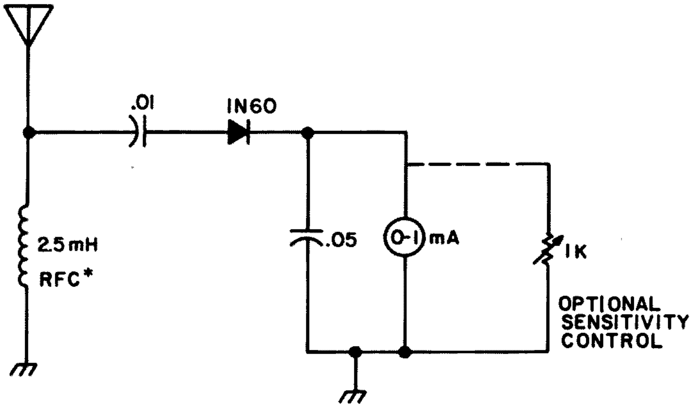

*Fig. 4. Schematic of a simple rf field strength meter. (*Can be replaced by an LC tank circuit for greater sensitivity or use as an absorption meter.)*

Troubleshooting Procedure

Troubleshooting involves a logical, step-by-step procedure for determining a fault in a piece of equipment. Best results in a minimum of time are obtained by using a method formed from a logical analysis of the problem at hand.

One thing which makes troubleshooting a darn sight easier is a service manual (or AT LEAST a schematic) on the equipment. It is the wise amateur who obtains (even at a ridiculous cost) the service manuals for all of his station equipment. In most instances new equipment comes with a manual; keep it. If you buy used or for any reason are without a manual, buy one and keep it on file. Do not expect your rig's manufacturer to be

The most valuable and versatile piece of "test equipment" is already in your possession: your head!

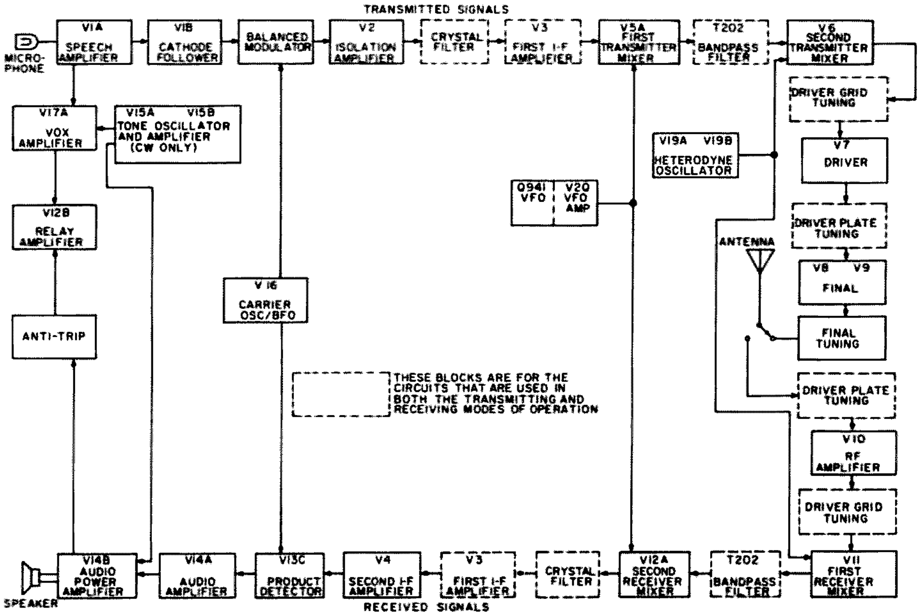

Fig. 5. Block diagram of a popular transceiver. (Courtesy of Heath)

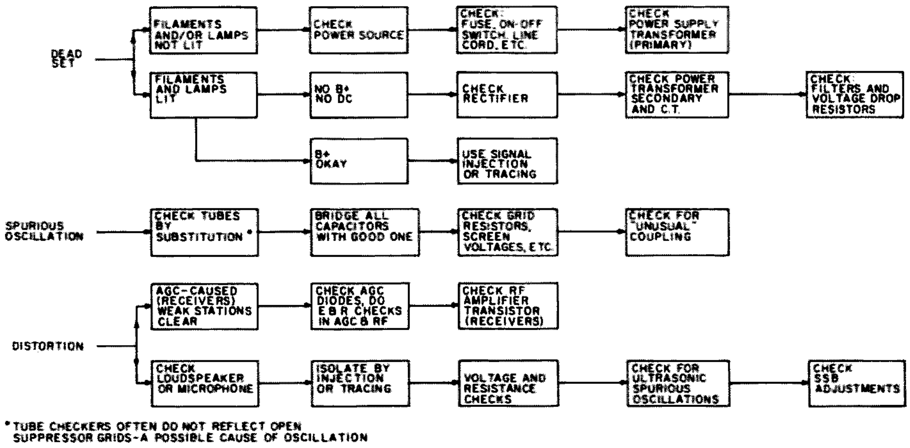

Fig. 6. Troubleshooting tree useful for finding a good jumping off point for troubleshooting specific defects.

The "screwdriver technician" is the bane of professional servicers everywhere . . .

able to supply manuals indefinitely; get yours now.

One significant aid in troubleshooting is the block diagram. It is especially useful in rigs such as transceivers where a single stage might have different functions. An example of a block diagram, this one from the popular HW-101, is shown as Fig. 5. You can often cut the work of troubleshooting in half by doing a "desk check" of the service manual and block diagram before reaching for instruments to do the "bench check." Note that many of the stages, shown here in dotted lines, are common to both transmit and receive functions. Although there are exceptions, you can usually overlook these stages when a defect affects only one function or the other.

The element of logic in troubleshooting should be almost an *a priori* truth (despite the philosophers who say that such cannot exist!). After all, if the set is dead (no lamps or tube filaments lit) is it wise to worry about, say, the beat frequency oscillator? Fig. 6 shows what is affectionately called a "troubleshooting tree." Although this is not offered as a universal approach you can often at least get onto the right track by its use; it is intended only to be a "point of departure guide."

Two terms pop up a dozen times in any servicing literature: signal tracing and signal injection. They are basically methods for locating a dead or otherwise defective stage. Before beginning one of these procedures, however, make certain preliminary observations. For example, can you hear noise in the speaker as you rotate the volume control? If so, the cause of the dead condition is probably PRIOR to the volume control. What about dirty contact noise as you rotate the selectivity switch? This usually means that the fault is prior to that point. Band switch noise (again, as you change bands) could mean a fault in the rf or a dead local oscillator. What about the level of "background" hiss (you know, as if you were tuned to a dead band)? High noise levels may tend to indicate troubles in the rf amplifier or antenna circuit. Here is one point where your calibrator is useful. Note how high the "S-meter" reads when the set is working normally. When a defect occurs, turn on the calibrator and see if it is lower. If not, suspect the antenna or feedline. These observations are of the sort that can save an awful lot of time. Most pros use them all day long even when unaware; it is the source of their supposed professional "intuition."

The process of signal tracing involves injecting a known and controlled signal at the input to a chain of stages, then looking for it at the outputs of successive stages with a demodulator equipment signal tracer (high gain audio amplifier with a fancy name!) or oscilloscope. When you find the defective stage, you can then use the VOM or VTVM to locate the bad part. In some cases, you might want to inject an appropriate signal at the antenna terminals while in others it might be better to inject another sort of signal at the input of the i-f strip.

Signal injection is a similar process. In this method you start at the output and inject an appropriate signal into the inputs of successive stages until you find one which no longer is capable of producing an output. In signal injection you begin at the output and work toward the input, while in signal tracing just the opposite situation obtains. In either event the procedure can usually be expected to ferret out the defective stage. Once found it is usually a simple matter to dig out the voltmeter and determine which component is at fault. Be sure not to overlook the obvious fault such as a bad tube or a loose connection. Once again, the

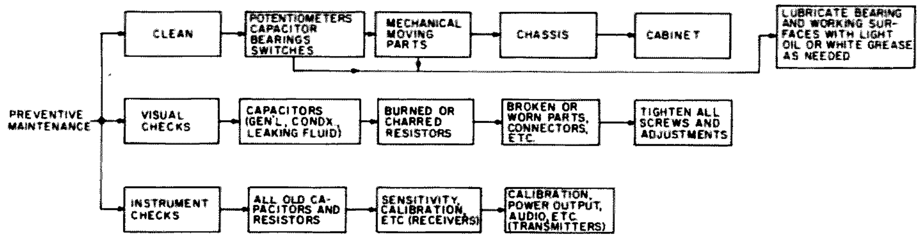

Fig. 7. Preventative maintenance tree.

observant are usually a bit more successful.

When troubleshooting transmitters, you can use a demodulator probe to find relative rf levels on the 'scope or VOM. It is usually better, though, to read the dc voltage developed by the grid leak bias often used in transmitter stages. This voltage will be proportional to the rf level delivered by the preceding stage. This system works so well that it is the basis for the Motorola "test set" popular with FMers who run surplus commercial Motorola mobile equipment.

Alignment

The most exasperating mark of the neophyte troubleshooter is a wild "diddle stick" (alignment tool). It is a pretty good rule to assume that alignment points NEVER shift enough to cause a gross fault in the receiver, especially a sudden fault. The only real exception is the local oscillator. Even in that "sometimes" case there are other methods (i.e., measure the frequency) for determining its condition. One telling thing that shows whether or not the stage is actually oscillating is to measure either the grid bias or the voltage drop across the emitter resistor as the set is tuned through the range (or in the case of crystal oscillators remove the rock). This will cause the bias to change suddenly for crystal pulling or smoothly in VFO type circuits. DO NOT EVER touch an internal alignment point without good reason, proper equipment and a knowledge of what it is that you are doing. You can diddle stick a decent set (that really only needed a small component) to death! This is why the "screwdriver technician" is the bane of professional servicers everywhere.

Preventative Maintenance

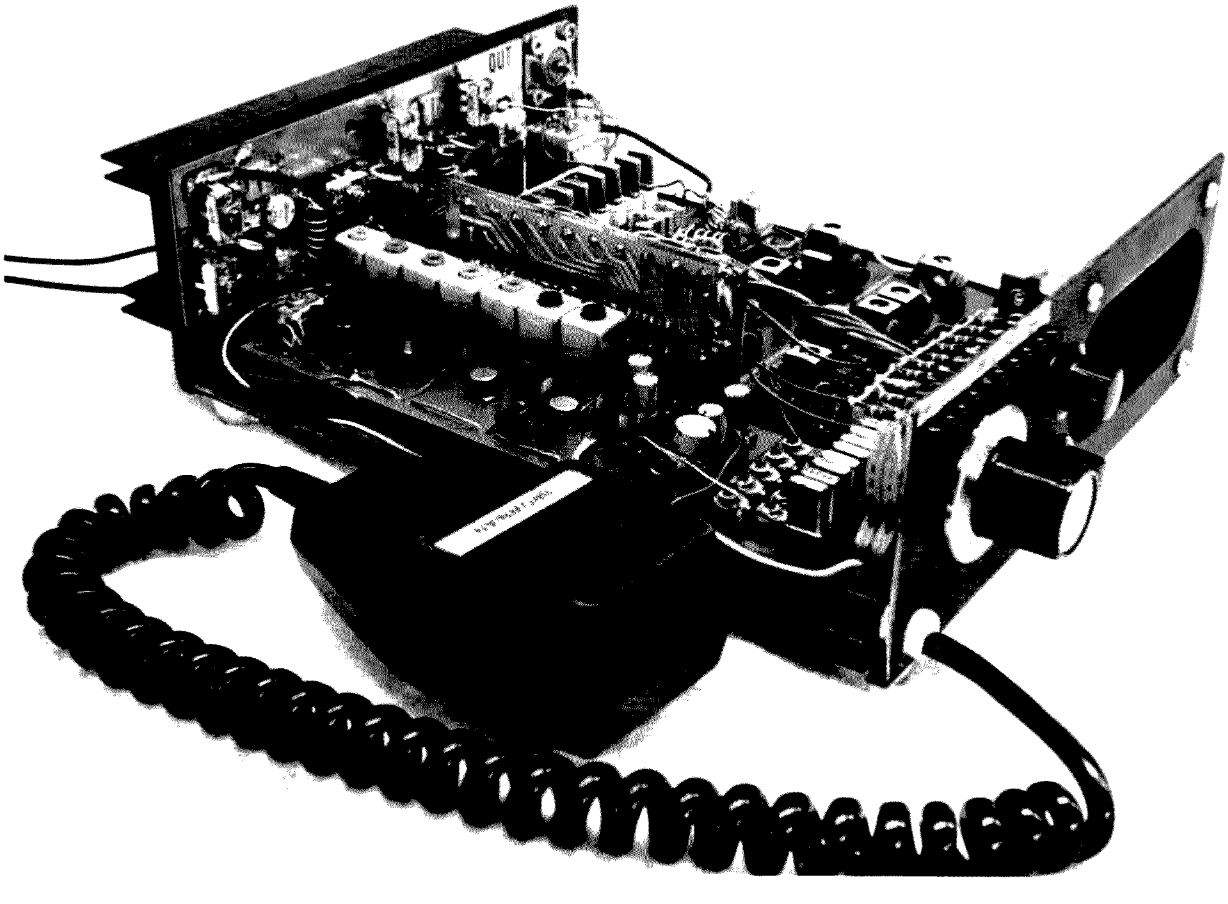
There are a number of little tasks which will keep your rig in top shape for a lot of years. These generally fall under the heading of "preventative maintenance" – see Fig. 7. One task would be to check all tubes on a periodic basis, say every six months or maybe once a year. Replace those which are defective or grossly weak. Some advocate doing a voltage check at critical points throughout the circuit especially in the power supply. It is recommended that you clean the inside of the rig, including all circuitry, with a paint brush and a mild solvent where needed. Use a switch/control (also called "tuner") cleaner spray on all band switches, function switches and controls. Clean capacitor and rotary switch bearings and relubricate using a white grease such as "Lubriplate." "Peaking up" alignment is NOT part of this procedure unless you can perform factory-level service. Even in that case it should not be obligatory except every few years. I know it sounds like harping, but alignment is simply not all that common a problem. In fact, after fifteen years of experience, I can only remember a couple of cases where alignment was genuinely needed (except where somebody played) and these were new and in-warranty sets! ■

A number of little tasks which will keep your rig in top shape for a lot of years fall under the heading of "preventative maintenance"...

Module Kits - A Low Cost Homebrewing Breakthrough

by
G. R. Allen W1HCI
80 Farmstead Lane
Windsor CT 06095
and
Bob Brown W2EDN
93 Gilmore Avenue
Binghamton NY 13901

With the high rate of inflation, it is more and more difficult for the average ham to afford a factory wired piece of gear for the VHF bands. For that reason, the authors have developed a modular approach to building a VHF transceiver for the 144 MHz or 220 MHz bands. By using a modular approach, the builder is not required to lay out a large chunk of cash just to get on the air. The builder may build a



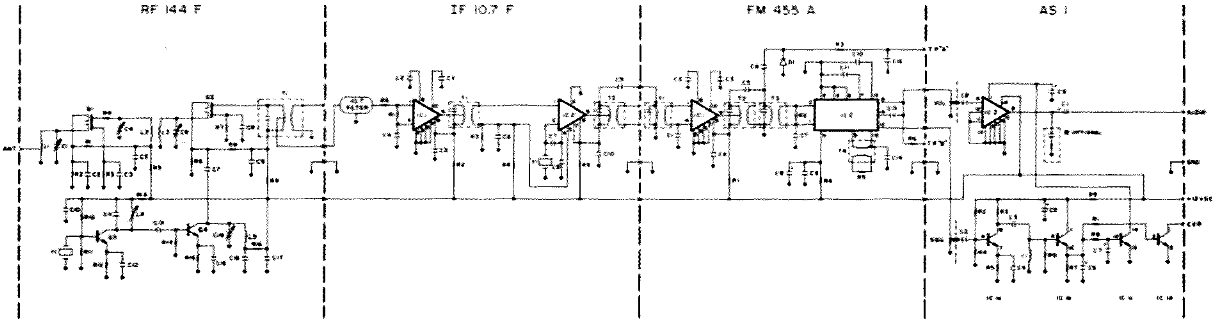


Fig. 1. RX 144 C schematic.

simple, basic transceiver and then add expansion modules and options as needs and finances dictate. Because of the fact that this modular approach requires the experimenter to build his own units, the experimenter will gain knowledge and knowhow and thus be able to maintain his own equipment should problems develop.

The transceiver described in this article may be built for either the 144 MHz or 220 MHz bands and will compare favorably to commercially wired units. The basic transceiver consists of a transmitter and a receiver operating as single channel units, and can be built for less than $100. Simple modules, such as multi-channel decks, channel scanner, and power amplifier, may be added to the basic transceiver to form a medium power, multi-channel, scanning transceiver for a cost well less than the commercially wired equivalent. The assembled transceiver may be operated on either 144 MHz or 220 MHz, depending on the kits purchased, and may be used in a breadboard fashion or mounted in a home brew or commercially available case. The builder may plan to construct the basic transceiver initially in order to get on the air for a minimum cost. At any time in the future the expansion modules may be added to multi-channel and/or provide higher power.

The units described in this article are designed primarily for 144 MHz and 220 MHz. The builder, however, will not be limited to these two bands in the near future. Currently, VHF Engineering has receiver modules available for 6 meters and is working on a 6 meter transmitter module. UHF 450 MHz transmitter and receiver modules have just become available.

It is impossible in a short article to give every construction detail required to exactly duplicate the transceiver described in the article. For that reason, basic schematics are provided for reference purposes only. Complete construction and debugging details are provided with the kits. Should the experimenter wish to build his transceiver from scratch, he may obtain boards and/or schematics and construction details from VHF Engineering for a nominal charge.

The Receiver

The VHF Engineering receiver kit used in this article is an RX 144/220 C. It may be used either on 144 MHz or 220 MHz merely by changing the coils on the front end rf board and by making a few minor component substitutions. The receiver draws 60 mA squelched and uses integrated circuitry exclusively except for the rf board. Sensitivity is .3 uV for 20 dB quieting for 140-170 MHz and .5 uV for 220-230 MHz. The receiver is dual conversion and is supplied with a 10.7 MHz 2 pole filter producing a 6 dB bandwidth of ± 10 kHz. The receiver will produce two Watts average audio output into a 4 to 16 Ohm speaker. The front end of the receiver uses a dual gate MOSFET for low susceptibility to intermodulation. The receiver kit is very easy to assemble, taking about 10 hours for the average builder. Alignment is done by using a signal generator, an rf probe, and a high impedance voltmeter (all borrowed, of course). Complete construction and alignment instructions are given with the kit.

Receiver Multi-Channel Option

The basic receiver is a single channel unit. It may be used as a single channel unit until such time as interest and finances lead to the desire for additional channels. When additional channels are required, the receiver can be multi-channeled simply by adding the VHF Engineering CD-1 multi-channel deck.

The CD-1 consists of a 10 channel deck complete with circuit board, sockets for the crystals, diodes, resistors and capacitors. Receiver channel switching is accomplished with a diode switching arrangement to permit manual switching of channels and automatic switching using the ten channel scanner. The completed 10 channel deck is plugged directly into the receiver as shown in Fig. 2. This receiver multi-channel kit is a

By using a modular approach, the builder is not required to lay out a large chunk of cash just to get on the air . . .

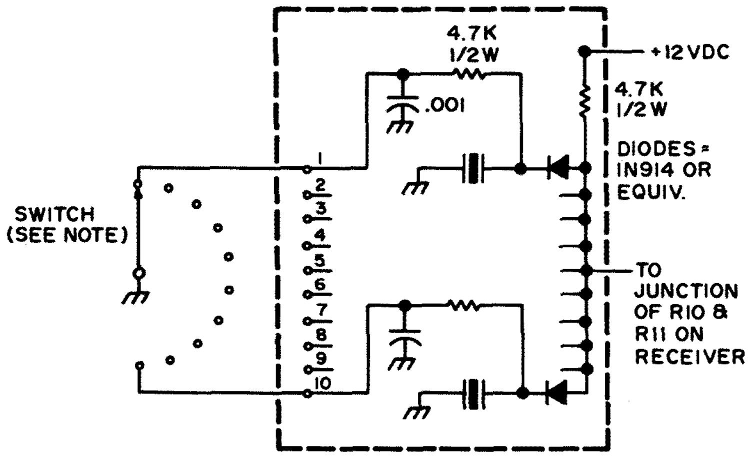

Fig. 2. Receiver multi-channel option. Note: Switch is part of transmitter multi-channel option.

versatile unit and may be used with most transceivers using crystals in the 45 MHz range.

Scanner Option

A channel scanner is a gadget extremely valuable to a true FM enthusiast, as it permits the operator to sequentially search selected channels for activity. All receiver channels are scanned automatically in sequence to see if a signal is present. If a signal is found, the scanner locks on the signal and remains on that channel as long as activity is present.

The circuit consists of a simple multi-vibrator operating into a decade counter and a decimal decoder. The output of the decimal decoder drives LED lights to indicate the channel being scanned. Switching diodes on the CD-1 multi-channel board are used to switch the crystals in and out of the circuit. A carrier operated relay connection is made to the receiver board to stop the multi-vibrator when activity is found on a channel. The circuit is easily defeated if manual override is desired. Either manual operation or automatic operation may be used.

The Transmitter

The transmitter is a true frequency modulated unit using crystals in the 12 MHz or 18 MHz range. It has an output of 1 Watt on 220 MHz and better than 1 Watt on 144 MHz. The only difference between the 220 MHz and the 144 MHz versions is the number of turns on the various coils. It is very simple to construct and may be tuned up by using a homemade rf probe and a small #12 bulb. Construction time is about 3½ hours.

Transmitter Multi-Channel Option

The basic transmitter is a single channel unit. While a single channel unit may be sufficient under some circumstances, the builder will very quickly require additional channels. The multi-channel option for use with the transmitter consists of a board, crystal sockets, and crystal trimmer capacitors needed to give the basic transmitter 10 channel transmit capability.

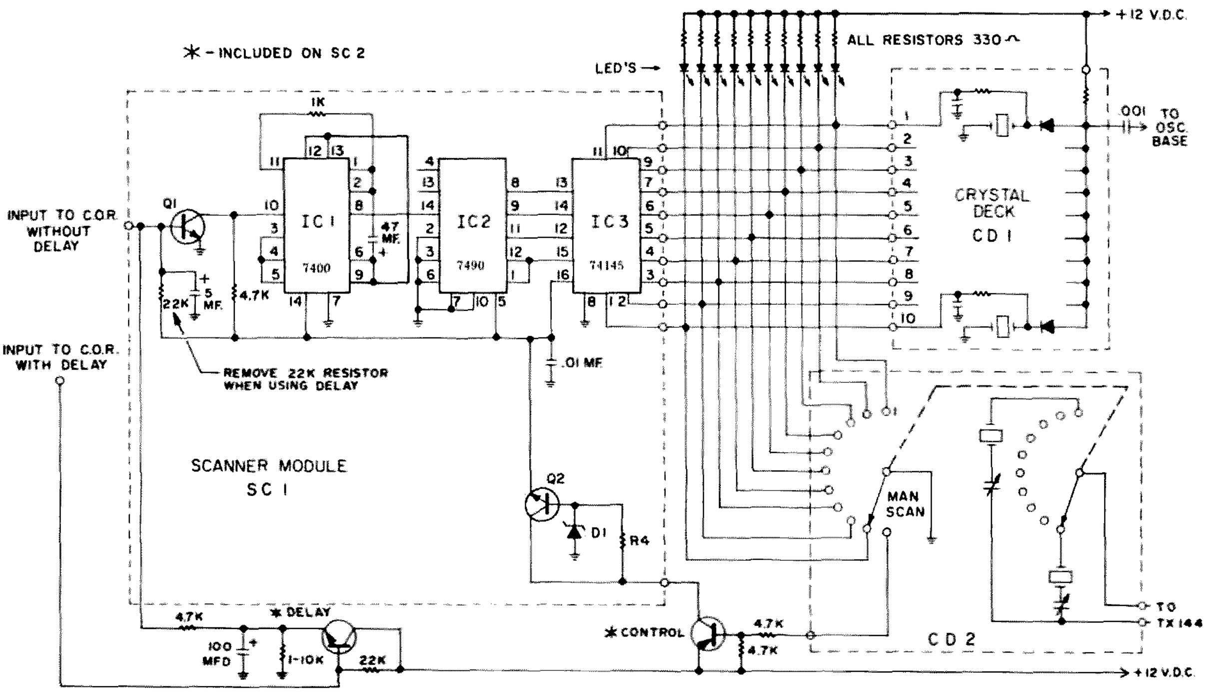

Fig. 3. Scanner option.

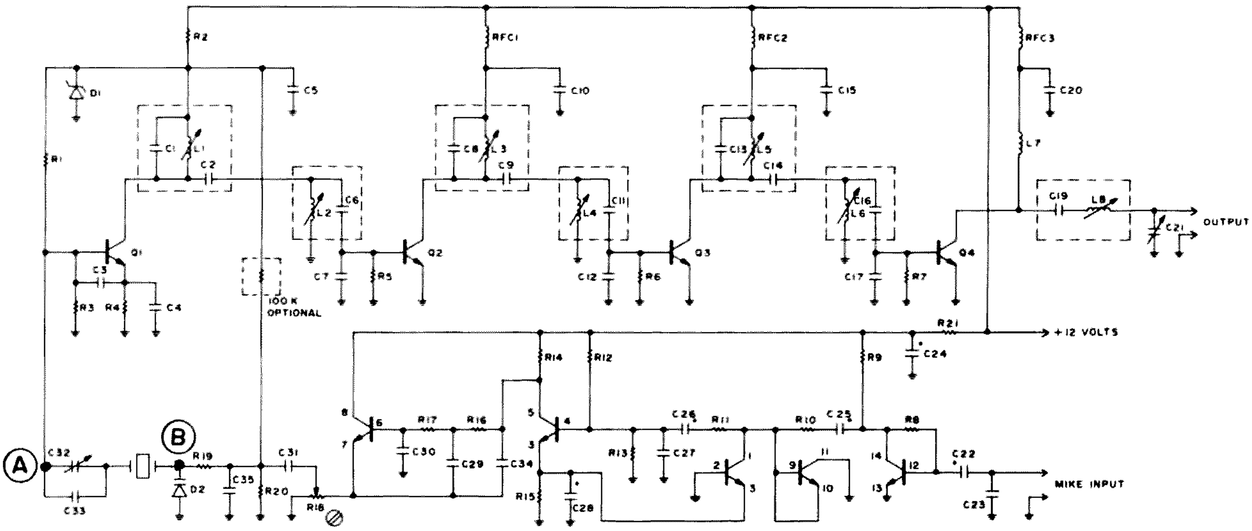

Fig. 4. TX 144/220 schematic. Note: Points A and B are connections for transmitter multi-channel option.

A multi-deck switch is provided for switching both the transmit and receive channels simultaneously. This unit is simple to build and may be constructed in about 20 minutes. Installation is shown in Fig. 5.

Power Amplifier

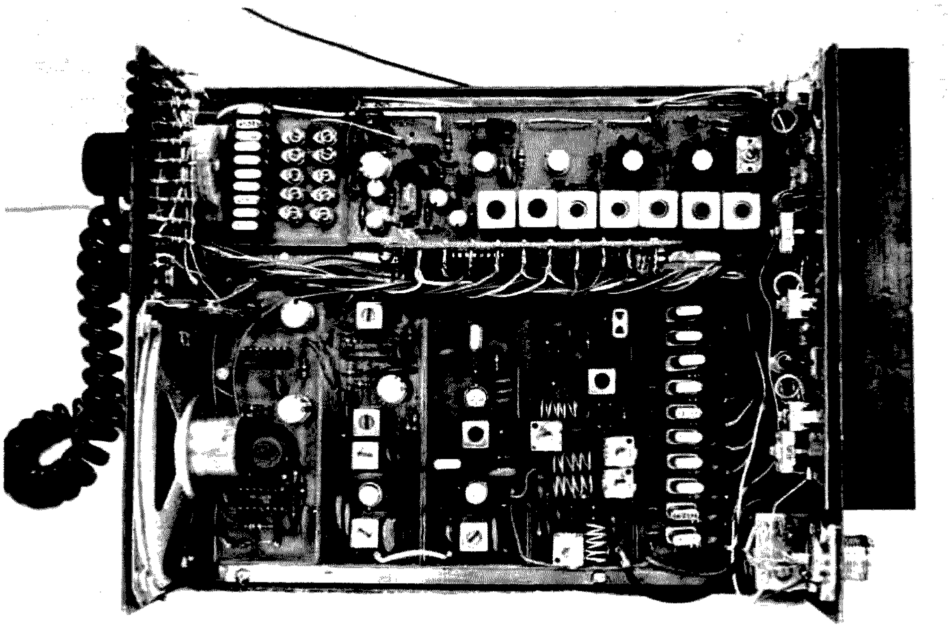
While one Watt may not seem like a lot of power, it is sufficient in most cases when the operator is using a repeater. In cases where direct operation is desired or where difficulty is encountered in hitting a specific repeater, a power amplifier may be desirable.

Two power amplifier options are available for the builder. Either the PA1501H or PA2501H may be used, depending on whether the operator prefers 15 W or 25 W. For the ten dollars difference in the price of the kit, I prefer the 25 W power amplifier. (Note that, for 220 MHz, only the 15 W amplifier is available.)

Both power amplifiers use two transistors in a broadly tuned common emitter configuration. Ratings on both units are conservative and the builder will most likely get appreciably more power out than the ratings indicate.

The Power Supply

A power supply is not needed for 12 V mobile operation, of course; however, it is a requirement for fixed station operation.



It's just poor practice with solid state equipment to give it the smoke test as a unit. Test everything individually to save time and trouble . . .

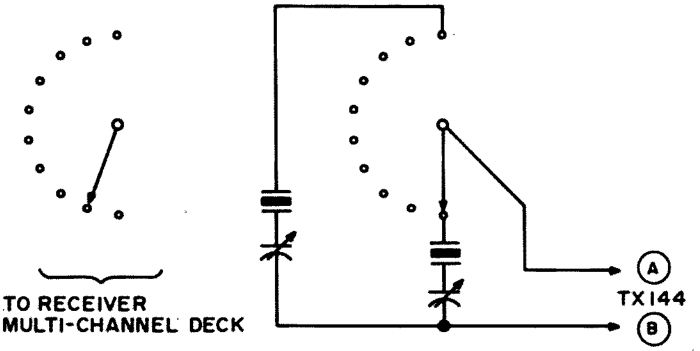


Fig. 5. Transmitter multi-channel option. Note: See Fig. 3 for receiver connections.

While an old car battery with charger may be used to supply the power for the transceiver, this is messy and inconvenient. The power supply used to power this transceiver (when used as a base) was the VHF Engineering model PS-12. It is rated at 12 Amps for 13.6 volts, which handles the transceiver and the 25 Watt power amplifier very comfortably. The power supply consists of a 550 voltage regulator chip driving two 2N3055 pass transistors.

Construction (See Photos)

A case with dimensions 9" x 7½" x 2¾" was used to house all modules. The size of the case is not critical, but the modules won't fit easily in anything smaller. The receiver and transmitter are mounted flat on the chassis as shown, using small standoffs to keep the boards off the chassis. The channel scanner is mounted vertically between the transmitter and the receiver. The power amplifier and transmit receive relay are mounted on the back panel along with the coax connector, the heat sink for the two power amplifier transistors and a small hole for the power leads. The multi-channel decks are mounted up front, with the switch shaft going through the front panel. The squelch and volume controls, the LED channel indicators, and a 2¼" x 4" speaker are mounted on the front panel.

Before mounting the completed modules in the case, it is important to thoroughly test each individual unit to ascertain that it has been wired correctly. It is just poor practice with solid state equipment to give it the smoke test as a unit. It is better to test everything individually to save time and trouble. Note that good instructions for test and debugging are provided with all kits.

This transceiver is very rugged, and requires no special operating precautions other than keeping it out of the rain and away from direct lightning hits . . .

Hookup

Interconnection of all components to make a complete transceiver is very simple as shown in Fig. 6. Number 14 stranded or solid wire or equivalent may be used for all power wiring. Good quality coaxial cable should be used for all rf wiring. Small diameter RG74/U may be used from the antenna relay to the receiver, while RG58/U may be used for the connections to the transmitter and the power amplifier. The relay used may be any double pole, double throw 12 V relay which will fit in the case you have selected. Contacts should be able to handle at least 3 Amps at 12 V and 25 Watts of rf at 148 MHz. VHF Engineering can supply this relay if you cannot obtain one locally.

A simple high pass filter consisting of a 22k resistor and a .022 uF capacitor in parallel is used in the microphone input to give better high frequency response for the transmit audio. Any 600 Ohm dynamic microphone may be used with the transceiver.

Operation and Performance

Several of the units as pictured in the photos have been used in the Binghamton, N.Y. area for quite some time now. The

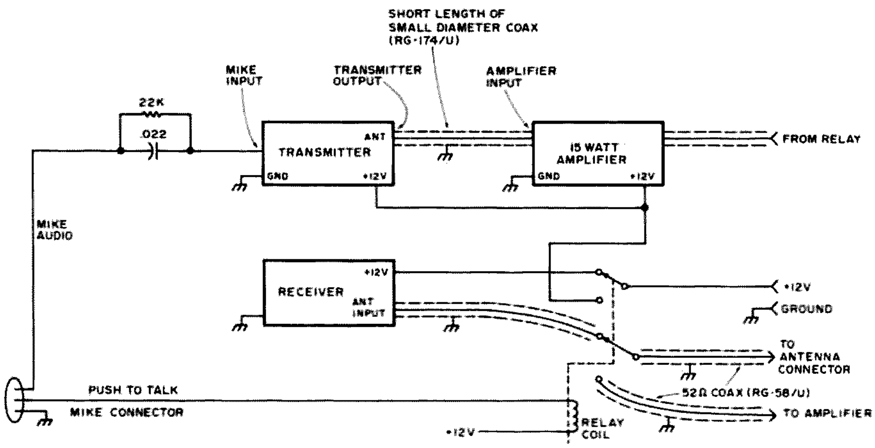

Fig. 6. Basic transceiver connections. Note: Relay may be any 12 V DPDT relay.

units have good audio on both transmit and receive and are virtually trouble free. Receiver sensitivity and selectivity are excellent when compared to most pre-wired commercially available units on the market. The transceiver is very rugged and requires no special operating precautions other than to keep it out of the rain and away from direct lightning hits.

If you ever check into the .22/.82 repeater in Binghamton, N.Y., the chances are good that you will work someone using a transceiver made from VHF Engineering products, and possibly one of the transceivers in the photos. Because of the simple modular approach and reasonable cost, you will also find a growing number of similar transceivers in use from coast to coast across the country. ■

Parts Lists and Board Layouts

Space does not permit the printing of complete parts lists and board layouts. To obtain parts lists, board layouts, and detailed assembly instructions, send $5.95 to:

What's All the Noise?

What is a good noise figure, 38-28-37? Oops! We are off on a tangent already and are getting way ahead of ourselves. Let us get back on the straight and narrow. First of all, what is noise? No, we are not talking about din but electrical noise. Static, for one, or atmospheric noise. Galactic (referencing galaxy) for another, or cosmic noise. Of course there is the ubiquitous man-made noise. Last but not least is thermal noise. This is the only noise used to compute noise factor. Thermal noise is circuit noise caused by thermal agitation of electrons.

Since all matter is comprised of electrons and only at absolute zero (-273° C.) are electrons quiescent, it follows that everything generates thermal noise. The higher the temperature an object is subjected to, the greater is the thermal agitation and consequently the greater is the thermal noise generated.

Starting with the antenna, it generates noise as does the coax, the antenna coil, the rf front end active device (tube, transistor, etc.) and as a matter of fact every component in a receiver does. This noise is added to the noise presented to the input terminals of the receiver and is amplified along with the signal. Noise introduced in subsequent stages does not get amplified as much and has little added effect. The overall gain of a good receiver can be 1,000,000 times voltage or 120 dB. 1 microvolt of noise introduced across the input terminals results in 1 volt of noise appearing across the output terminals. One microvolt of noise introduced after the rf stage is only amplified by possibly 100 dB and appears as only 0.1 volt across the output terminals. One microvolt of noise introduced in the i-f stages may only be subjected to gains of 10 dB to 90 dB depending on which stage generates the noise and has no appreciable effect on the output noise.

The noise introduced at the input terminals is subjected to the same overall gain as the signal is. The ratio of the noise measured at the output to the noise measured at the input is called the noise

factor. A simpler way to express noise factor (more commonly called noise figure) is as a power ratio of the signal to noise ratio at the output as compared to the signal to noise ratio at the input. It is a ratio of two ratios expressed in dBs. A receiver with a 10 dB noise figure degrades the signal to noise ratio by 10X. A 5 to 1 signal to noise ratio at the input terminals becomes a 1 to 2 signal to noise ratio at the output. We have degraded from a signal 5X stronger than the input noise to one ½ as strong as the output noise. One would not be able to copy this signal. On another receiver with a 3 dB noise figure it will only degrade this same 5 to 1 signal to noise ratio of 2½ to 1 at the output thus still permitting armchair copy.

We can effectively change the signal to noise ratio of a receiver by adding a low noise preamp ahead of it. In essence you substitute the noise figure of the preamp for that of the receiver. The input terminals are now that of the preamp and not that of the receiver. That (ugh!) 10 dB NF (noise figure) receiver that we used for illustration before with a 2 dB NF (ultra quiet) preamp ahead of it is now effectively a 2 dB NF receiver. Let us keep in mind that the change works equally in reverse. A beautifully quiet 2 dB NF receiver with a (ugh!) 10 dB NF preamp ahead of it is now effectively a noisy pile of junk.

The noise figures used in the above examples were only illustrative. A 2 dB NF may be too expensive to be practically achieved in production. Much better than 2 dB NFs have however been achieved in the lab. I will settle for 3 or 4 dB anytime.

Noise figures are much more significant at VHF and at UHF than at HF. Try this simple test and convince yourself. Remove the antenna connector from an unsquelched VHF or UHF receiver and you will not hear any change in noise level. You may even find one that in fact goes up. This is caused by the input coaxial line removal unloading the input terminals permitting the input noise resistance to increase developing greater noise voltage across it. This will not happen with a properly designed input circuit. By removing the antenna connector from an HF receiver, however, you will find that the noise level drops considerably. The lower the receiver frequency the more pronounced will be the effect. At VHF and UHF most of the noise that we hear is

manifestly generated within the receiver as thermal noise. At HF it is mostly externally generated and represents galactic, atmospheric and man-made noise all picked up by the antenna.

If you have a relatively high NF VHF or UHF receiver, this does not mean that you will not be able to copy signals as full quieting. It simply means that you will require a stronger signal since your signal to noise ratio is lower. It is the fellow with the low NF receiving system that hears those weak DX ("down in the noise") signals that you do not even know are there. Even stacked 11 element beams at 50 feet do not help much. I would rather "pick up" extra gain by lowering my NF. It is cheaper and you do not have to "sweat" the high winds, the ice and the snow. ■

Ham Q Quiz

Glen E. Zook W5UOJ
K9STH 410 Lawndale Drive
Richardson TX 75080

The past few years have shown a remarkable renewal of interest in items and memories of by-gone days. This phenomenon, known as nostalgia, can be carried over into amateur radio. Thus, a list of 100 bits of trivia from the post World War II era has been compiled and listed below. Keep track of just how many you recognize and check the scoring at the end of this article.

Do you remember:

When *73* cost 37 cents?

When there was no *73*?

When Leo had hair?

When Allied was a ham store at 110 N. Western?

30Ds and 16Vs?

The "Old Yankee" and "No kids, no lids . . ."?

When a Hertz was a rental car?

My QTH QSL cards, and those orange ones from Walter Ashe?

The Drake 1A?

When Wayne was an RTTY Editor?

When a base was at Yankee Stadium?

And a collector was from the finance company?

When an 807 was a final and not a drink?

The "Gentleman's agreement" on 20 phone?

When the DX100 and Viking II were king?

BC 459, 455, and 696?

Hunter Cyclemasters?

ICE (not rice) boxes on 2M FM?
When W9IOP won the SS almost every year?
AR3s and AT1s?
Gooney boxes that stared back at you?
The NBFM craze?
Cutting the supressor grid wire on 1625s?
When 11 meters was a ham band?
When we got 15 meters?
When International Crystal built ham kits?
Geloso VFOs, Receivers and Transmitters?
The "Dream Receiver" (the one I had was a nightmare)?
Pacemakers that weren't a medical device?
When Novices could operate 2M phone and Techs not?
HFS and NC173s?
Swan 120s, 140s, and 175s?
When a Tempo was a music speed?
Globe Chiefs, Scouts, and Kings?
When a drain was in the middle of the sink?
And a gate was a part of a fence?
Finding out your new call from the Little Print Shop?
When ham licenses were free?
Lincolns and Little Lulu?
When the KWM-1 was the latest thing out?
When there wasn't an S-Line?
When Novices were Crystal controlled?
Link and Dumont?
6AG7s in GG?
20As and tubeless VFOs?
2As, 2Bs, and T-4s?
Invaders and Marauders?
Bandits and pedestals?
Thunderbolts, Challengers, and Harvey Wells?
813s modulated by 811s?
Well, persons, you are now at the mid point of this great listing of amateur radio trivia. How ya doing so far? Well, it's back to the old list. Do you remember:
Swan Mark I and Heath Warriors?
Senecas, DX35s, DX40s and controlled carrier?
When there was only **QST**?
When there were two?
FM Journal and *rpt*?
Cosmophones and Eldicos on SSB?
Model 12s and 15s not those quiet 28s?
Sunspots, with JAs on 6?
When KWs were built, not bought for $200?
Building your first transmitter?
Your very first QSO?
When portable meant carryable by two persons?
CK722s?
Peanut tubes and acorns too?
Comet, Apollo, Zeus, and Venus?
FM210 plus PA210 from Galaxy?

Globe Champs and 'trotters?
Four-20s and Super Pros?
Gladding, Genave, and Varitronics too?
Prop pitch motors and selsyns with gears?
Morrow and Lakeshore with Sonar to boot?
When a Sentry was a soldier?
When a Swan was a bird?
When Birds only flew, not just read watts?
When Wayne was Editor of that "other" magazine?
6-up?
Carbon microphones and high impedance headphones?
Nuvistors?
When a California Kilowatt was just that?
Your first Field Day?
Mel Shadbolts TV handbook?
Gotham ads didn't have "20 Meters is murder..."?
When the average novice station was a DX40 and SX99?
Ringos and Rangers?
Tuning units from BC375s?
Plug-in coils?
6AG7-807, modulated by Pr. 6L6s?
1296 and APX6s?
SCR522s?
When Tandy only sold leather?
Flying spot scanners and the 931A?
Polycoms on 6 and 2?
Multiphase Products?
Cheyennes, Comanches, with Pawnees and Shawnees?
416Bs and 417As?
1625s at 25 cents each?
Radio Row?
When JAs were "rare"?
Your first DX contact?
Star Roamers and Ocean Hoppers?

Some readers may feel that enough information has not been given in the above quiz. However, if you really recognize and/or remember the trivia then you won't need more information. Be fair and score yourself according to the following:

0-10 "Honey, that's Daddy's *73*, your *Sesame Street Magazine* hasn't come yet."
10-20 The "Arkansas Aardvark" is on channel 11.
20-30 Better, but you're still wet behind the ears.
30-40 You can hold your own at the local radio club.
40-50 Venture forth on 20 meters.
50-60 You're a full fledged ham.
60-70 Qualified to B.S. at any convention.
70-80 Ready for 75 meter phone.
80-90 Qualified to write trivia for *73*.
90-100 "Hiram Percy who????" ■

Saving Ham Radio

You've seen it in every ham radio publication you've picked up lately. Our hobby is in trouble!

The editors of the magazines think so. That's why they are editorializing. The equipment manufacturers think so, too. That's why they are slowly going out of the amateur radio business. How many of them would still be with us if it had not been for the two meter boom? The FCC recognizes things are in bad shape, also. Those sweeping licensing structure changes we've heard rumored about so long are now official proposals. The Commission knows it must have numbers behind it in Geneva in 1979...numbers to back up requests for more of the spectrum, or just to hold on to most of what we now claim as ours.

How can we save our hobby as we know it? Obviously, we must get more people into ham radio. As I see it, we have two great obstacles staring us in the face, though. One: that great mass of amateurs out there in radio land who either are ignorant of the facts or regulatory life, are concerned but are too darn lazy to do anything about it, or are too short sighted (the famous.......fewer-hams-equals-less-QRM-for-me syndrome). When these guys are left with nothing but the upper megacycle of ten meters in which to pursue their hobby, they will probably be the first to point their fingers at Newington, Wayne Green, and the other more visible spokespeople for ham radio and let out a multi-decibel "Wha' happened?"

Obstacle number two, I believe, are the new FCC proposals, well intentioned as they may be. I'm afraid they will tend to make more than a few potential amateurs hold off on getting started. Why should I start work-

ing on that impossible-to-learn code when I can just wait a spell and get on two meters without it? Why don't I just wait for the dust to settle? We are all prone to procrastination. And regulatory wheels grind exceedingly slowly in these bureaucratic times. I am afraid the licensing structure is to be in limbo for some time yet. Whether docket 20282 is designed to save amateur radio or to bail the FCC out of the CB quagmire is beside my point. It can only serve to further becloud the problems we already have.

But before this article gets too depressing, I think I should hasten to add that I think I see some hope. I don't think W2NSD, ARRL or the FCC can bail us out of this one. I think Pogo said it well: "We have met the enemy, and he is us." We are our own enemy if we allow apathy, ignorance or myopia to destroy our hobby. I think it is time the quarter-of-a-million of us who are hams took the bull (if you will pardon the expression) by the horns.

Fact: ours is the most fascinating and enjoyable hobby going. What other hobby offers as many exciting facets as amateur radio, mixes so well with other interests, offers so much opportunity for public service, and gives so many chances for personal accomplishment?

Fact: it just ain't that hard to become a ham. Any average moron can learn the code and enough radio to get a license. There are beaucoups books, courses, cassettes, tapes, study manuals, Q and A manuals, etc., available cheap. Help is there for the asking in most places. It is an honor to get a license, sure, but anyone with the will to learn and the gumption to apply himself to something worthwhile can do it.

Think back. How did you get started? Probably, you lived near a ham, worked with one, or had a brother-in-law who fooled around with the stuff. Most people started that way. Does that mean you have to live next door to a ham or marry his sister to get into the hobby yourself? It is ironic that a hobby that is based on communications depends on word-of-mouth for its growth.

We have a hobby we should be yelling and screaming about, and we sit on it like it's the map to the Lost Dutchman mine. When was the last time you demonstrated the two meter rig for the guys at the office? Or originated a message for some neighbors? Or volunteered to give a talk on ham radio for your civic club?

That, folks, is PUBLIC RELATIONS!

And ham radio PR is lousy!

Far too few people know what, who or where we are. That image of an eccentric radio nut wiring up his basement and screwing up the neighborhood TV reception is still going strong. And no wonder practically everybody persists in asking if I still have that "CB" in my car.

Next question: *why* is ham radio PR lousy? Because it takes initiative, inspiration and sweat. I certainly think the state of our hobby, and the prospects for its death (at least as we know it), should provide enough initiative. I am about to list ten ideas I hope will give you or your group some measure of inspiration. But there's not much I can do about the sweat part. If you are not willing to work some to see that my son and your kids (and maybe even you) have a hobby in a few years, then maybe ham radio isn't worth saving after all.

Some of the things I'm going to mention are not new or especially imaginative, but maybe you never thought of them before. Some have been, or will be, tried by the Birmingham Amateur Radio Club with varying degrees of success. If you give them a try, look out. You may run into brick walls with some. But you will get far better results than you dreamed with others. I only hope you will take the ball and run with it. It is fourth down and time is running out.

1) Get yourself or representatives of your group on a television or ratio talk show. The stations have to come up with an interesting show every day. Do them a favor and volunteer. It is best to tie in appearances with the start of your club's code-theory class (you club does have such a thing, doesn't it?), Field Day, or the like. Make sure interested parties can get in touch with someone for more info.

2) Land a feature story in a local newspaper. A story about a handicapped ham or a local amateur working through Oscar should be the answer to an editor's prayer on a slow news day. Make sure the editor knows how to get in touch with you and that you have a feature idea or two anytime he needs it.

3) Tie yourself in with local events. If you or your club provides communications for a parade or during a disaster, phone the newspapers, radio and TV, and tell them. They may never know otherwise. We got good newspaper and TV coverage when a Birmingham amateur heard first hand

about the recent Peruvian earthquake. He called local media and soon found himself entertaining a television news film crew.

Don't be modest! Look where PR got Hugh Hefner.

4) Get a booth at the county or state fair. Sure, it's a headache to keep the booth staffed and handle all that junk traffic. But notice how many people come back to ask questions.

5) Demonstrate your radio for school science classes. The League has a great OSCAR demonstration geared toward schools, too. And the club could probably spare a little beer money to put ham radio books in some school libraries. Be sure to stamp your address or the club's address inside the books.

6) Show off ham radio to the Boy (and Girl) Scouts. Invite troops to club meetings and hamfests, show them ham radio films, attend their get-togethers and answer their questions. Check with local scouting officials. They are in the phone book.

7) Set up a booth at the next Citizen Band jamboree, or what ever they call them. What!?! No, I'm not blowing a final. How many frustrated hams do you imagine there are on 27 MHz? How many would gladly go straight and sin no more if they knew what we are really all about? Some of the best hams I know are reformed CB types.

8) Man a demonstration station in a shopping center. More junk traffic and interminable Muzak, I know, but it sure gets to the people. But, you say, you mostly get women into those places. Don't you agree that one of the biggest weaknesses in ham radio is the failure to attract more of the ladies into our midst?

9) Fire off a news release to the papers at the slightest excuse. Write the release up in newspaper style or like radio spot announcements and send it in. Some will never see print, but none will if they are not sent in. Club activities, interesting occurrences on the air, the implementation of some of the other projects mentioned here...all make good stories.

10) Be a spokesman for ham radio every chance you get. Stand up at your Lions Club and announce the next ham club meeting. Present a program on ham radio to the Jaycees. Explain to the guys at the bar the difference between ham and CB radio.

All this sound like too much trouble? See you in the upper one megahertz of ten meters! ■

Washington Court House OH 43160

Patching Tales

Over many years of phone patching there have occurred many memorable incidents, some sad, some hilarious. I would like to relate some of both.

One morning about 3:00 a.m. the phone rang, and I was asleep. I answered, and the operator asked, "Are you Jerry?" I said I was. She replied, "I have an emergency call for you." The caller said, "This is John Katsafrakis. I am at Stanford University, and we must get through to Byrd Station, Antarctica. Can you get them for me?" I called Eights Station and raised Byrd via Navy telegraph. I ran a half hour patch, and when it was finished, Dr. Katsafrakis told me that they had released a space craft from Vandenberg Air Force Base, and it was tilted. Someone tried to correct it, and had overcorrected, causing it to tumble. They wanted readings over the Pole, and also predicted that it would fall to earth soon, which it did. I asked him how he found me. He said, someone said "try Jerry in Washington Court House," so I called the operator and got her to find you.

One of the incidents in my phone patching gave me a certain amount of amusement, and yet it was very sad for one of the principals.

A Navy man named Sam was stationed at KC4USM, the "Radio Noise" station about 1¼ miles from Byrd Station in the Antarctic. One night he called me with a plea for a phone patch to Boulder, Colorado. He had received in his mail, which arrived just before the Winter closed all flights to the Ice, a letter from his fiancee that really shook him up.

Frank, a good buddy of his on the summer crew who had left on the first plane out, had stopped in Boulder to see Sam's fiancee and deliver Sam's messages of love. Frank found he liked the young lady himself, and after a quick courtship they became engaged. Frank was on the way to a new duty station in the Canary Islands. The girl, Alice, agreed to get married and go to the Canaries with him. She wrote Sam and told him this.

Sam was desperate. He could not get any letters out for nine months, and could not send tapes. He begged her to wait until he could get a tape to her, but she refused.

She said, "You never

asked me to marry you, you simply said you were going to the Antarctic, and would see me in about a year. Frank and I get along with each other much better than you and I, and we agree on many things. I am in love with Frank, and to wait for your letter would be useless." He told her he had great plans, and so forth, but she was firm and refused. The patch lasted about an hour, and was one of the best I had ever run. Sam was very appreciative, but downhearted. I was glad that he had not been in the predicament of having to argue his case with a poor signal. For a year afterward, I heard on the air remarks about Sam and his patch. We must have had one of the greatest listening audiences in ham history. He said he was a quiet, scientist type, and not given to expressing himself. I kept thinking back to the John Alden story, with one difference. Frank said to himself, "Speak for yourself Frank."

One of my more weird patches came one night on a patch to nearby Columbus, Ohio. I gave the operator the number, and a man answered. I asked for Jean. He said "Jean is not here any more. She married that guy over at Lancaster when her husband died. Who did you say is calling?" I said, "It is her husband from the Antarctic, South Pole Station." He replied, "Well, I'll be darned. I thought he was dead." I dropped the line for a minute, and heard the man at South Pole saying, "Jerry, you have the wrong number." I went back to the other man just in time to hear him say, "I'll tell her" and he hung up. I asked the operator to redial it, and found that she had misdialed the prefix. I got another Jean at a different prefix in Columbus, and got the wrong suburb.

Once I had an experience that made me appreciate helpful operators. I had a call to South Carolina, but got a wrong number. I had the operator redial it, but still got no where. I asked the operator what the number was for the person I was calling, after checking with the man at South Pole Station for confirmation. She told me it was an unlisted number. I explained the circumstances, that the man was in Antarctica and wanted to call his wife and had no other means of reaching her. She was adamant. There was an absolute rule about giving out unlisted numbers.

I said, "I think I have the number almost right, perhaps I am off only one digit." She said, "Why

don't you try running it down one digit at a time?" I said "Do you mean getting ten people out of bed at 3:30 am?" Her reply was, "Oh, it won't be that bad. Why don't you try it, starting at the bottom?" I thought that over and decided she was trying to tell me something, so I called the number again, with 1 as the final digit, and got my number. She came back after the call, and I thanked her. She said, "You are very quick." I felt real good about such a nice operator.

My very longest patch lasted an hour and a half and was a series of relays. A man at Byrd station wanted to talk to his fiancee in Hawaii, as she was to leave there in a week and go to San Francisco to meet him when he came home in a few weeks. She was in a hotel in Maui, and I did not have any chance of getting a direct patch. I ran down a station in Honolulu, KH6HP, in a downtown office building. He could not hear Byrd Station, and Byrd could not hear him, but both stations were copying me fine. However, I was using phased verticals, so when I was talking to Honolulu, Byrd Station could not hear me, and when I was talking to Byrd Station, Honolulu could not hear me, so it was a real slow operation. Byrd to me, to Honolulu, to Maui. KH6HP had no patch, so it was all one way. The reply came from Maui, to Honolulu, to Ohio, to Byrd Station. KH6HP had to take notes and then try to get the messages straight to me, then I had to do the same to Byrd, since nothing could be sent direct. Then the whole thing had to be repeated going west. We got all the information passed, and confirmed. When I finally signed with KC4USB and KH6HP, the phone rang. It was the mother of a man who had been stationed at Byrd Station a couple of years before, and who had a receiver and vertical antenna, and who was listening. She said, "Jerry, how I wish I could have had a recorder to record that patch. It was the finest thing I have ever heard." I had patched her son many times when he was there at Byrd and she had gotten him to put an antenna up for her, and bought a receiver, and she sat up at night listening to Antarctic patches. I appreciated her call. She lives in Decatur, Indiana.

There was another time I had to run a patch for John Katsafrakis in Palo Alto to Byrd Station which I feel was rather interesting.

I got a call on the phone

from John, and he had been trying to get a message to Byrd and no one seemed to be able to raise them. He had scheduled a space craft to be launched from Vandenberg Air Force Base in California at midnight EST and had to postpone it because they could not get hold of Byrd. They had then rescheduled it for 1:00 a.m. EST and now it was almost 2:00 a.m. and they absolutely had to cancel if it passed 2:00 a.m. because of another launch being scheduled.

At 1:30 I called McMurdo Sound, KC4USV, and they had been unable to raise any other Antarctic Station all evening. John Katsafrakis had scheduled this launch with plans for no other station than Byrd to take readings. All the time and expense would be down the drain if they didn't get hold of Byrd Station soon.

I remembered that K1TWK in Ipswich, Mass. had a Teletype going into McMurdo which also ran to Byrd Station. I phoned him and got him out of bed, and told him to get a message to Byrd in a hurry. I gave him the name of the man wanted. With the phone line open to California, and the receiver set on 7.290 MHz, our regular traffic frequency, at 1:58 a.m. the man John wanted came through ready to go. They signaled the space craft and the launch took place at 2:00 on the dot.

After the furor died down, I asked the men on the Ice what the problem was. No one had realized that it was MIDWINTER'S NIGHT. This is the greatest celebration in Antarctica. It is the night the sun starts back South, and the mid point of the long Winter night. All stations shut down and the men gathered together for a grand and glorious drinking party. They tried to get through from Byrd Station as soon as they got the Teletype, but could not raise us because of weak signals. Three of them ran the 1.3 miles to KC4USM, Radio Noise Station, which had a better V antenna, and arrived in time for the launch. It was pitch dark and cold and they had to follow a hand line for safety. They knew nothing of the launch because no one had dreamed that Byrd would not be obtainable. It was the usual practice for the two or three men at KC4USM to go into Byrd Station whenever there was any kind of party, to join the 30 or so men at Byrd. It was also common practice to take two or three tubes out of the KWM2A at the stations so no drunk would get on the air and start running "patches."■

Work a Novice

One of my amateur friends told me that he was anxious to increase his code speed and that he was putting in more time on CW in order to obtain his Extra Class license. He mentioned in passing that he would go searching for a QSO, and if he found no takers on the low end of the band, he would migrate up to the Novice segment and work a few of the newcomers just for practice. This remark stuck in my craw. Late one night, when the long "skip" was in effect, I found no CW signals on the low end of forty meters, only Mexican phone stations, so I tuned up to the Novice segment.

After getting accustomed, I found this subband to be a beehive of activity, more often than not. Some of the signals may be a trifle difficult to copy, but by and large they are not vastly different from those to be found in other sections of the same band. It stands to reason that most of these chaps are sending at a slower rate than you will encounter in other CW sections of the band, but again there is no hard and fast rule. Some of these younger operators are quite proficient with the key.

Most of the Novice operators that I have worked were pleased to have made contact with another amateur with a General or higher class license. They impress me as being eager to learn, so you might try to set a good example when you work them. Some operators may regard this as some kind of chore, but really, it isn't. You might look upon it as a bit of enlightened self-interest, for you are helping to mold — hopefully for the better — the OMs that will be the Generals and higher rated licensees of the ham bands of tomorrow.

Sometimes when I find no particular satisfaction in some QSO that I've experienced on the low end of the band, I make it a practice to go up in frequency and work a Novice or two. Perhaps I never did look upon these QSOs from the Novice point of view until a YL operator from the New Orleans area included a short note, along with QSL card, thanking me for taking time out to come up and try for QSOs in the Novice sub-band.

If you happen to be on

either coast, or possibly in a hard-to-get state, you may find yourself quite popular. In my own situation, I find lots of WN6 and WN7 hams pleasantly surprised that their relatively low-powered rigs are able to span the continent..... these QSOs are often after midnight, but judging from some of the enthusiastic remarks on their QSL cards, you would think they had succeeded in contacting somebody on Mars!

If you have a little time to spare, and a small measure of patience to go with it, why not tune up to the Novice segment of your favorite band? Chances are you will be pleased by what you hear. You will learn that amateur radio is not going to the dogs after all. And here's your chance to make it just a little bit better. Why not give it a whirl? ■

Capacitors Unmasked

When a circuit refuses to behave the way it's supposed to, one of the places to look for a cause is the capacitor. Disc ceramics and electrolytics are popular because of small size and price, and most of the time they do the job in bypassing and coupling applications. When you measure the impedance at audio and rf frequencies, however, many of them look like anything but a capacitor.

In disc ceramics and the older paper types, a major cause of non-capacitive behavior is dielectric loss. In some materials, a fast-changing electric field outruns the ability of the material to keep up, so energy must be spent to establish the new value of the field. Since energy can only be drawn from a circuit when the current has a component in phase with the voltage, the capacitor acts as if it had a resistor connected across it. Neither the resistance nor the capacitance is necessarily constant with frequency; the resistance probably won't be. Ceramic capacitors rated under 100 volts may have as little as 1/10 of the marked value at 1 MHz even though they measure up at dc; higher voltage discs are more likely to be the other way around. Types vary, so this rule only serves to illustrate how widely values can fluctuate throughout the spectrum. I have only one actual value for a shunt

resistance. A 20 pF disc that I tried to use in a crystal filter looked like a 10 k resistor at 700 kHz, and it lowered the Q from 5000 to 3. So beware of using these things in tuned circuits.

Most people have heard of lead inductance, in which the leads of a capacitor act like an inductor of a few nanohenries, causing the component to series-resonate somewhere in the VHF region. Electrolytics can also develop inductance around surface irregularities in the foil, as well as in the foil itself, causing a resonance in the audio region, after which the impedance climbs rapidly. This is why you'll often find a small bypass capacitor connected across an electrolytic in commercial gear.

Another HF and VHF effect to consider is skin effect in the leads. Rf current doesn't penetrate metal to any great depth, so the leads look much smaller than they really are. Their apparent resistivity rises with frequency, and may put a significant resistance in series with the capacitor. This can be handled the same way as lead inductance: Shorten the leads to an absolute minimum, especially in VHF equipment.

Sometimes a capacitor, especially an electrolytic, may turn up with a true shunt resistance due to leakage. It doesn't have to be internal, either. If a suspected unit looks dirty, try washing the outside of the case.

The point of all this is that a capacitor, or for that matter any component, is never as simple as its symbol or diagram. When a newly designed circuit misbehaves, that fact could be important. ■

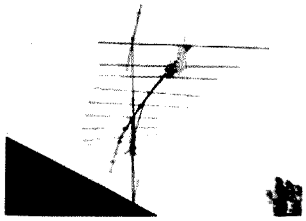
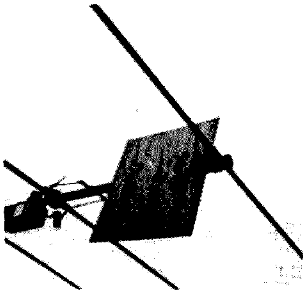
Why Fight It?



Windmilling is synonymous with large antennas and rotors without braking facilities. If your beam antenna never turns in the wind then FB on to the next article. However, if your beam is a "Horatio Hornblower," then read

on. Actually this gets into the psychology of the thing. If you will bury your pride and admit that the darned thing turns every time the gusts blow, and that the built-in gear torque is insufficient to stop it, half your problems are over. "Why fight city hall." Now the only major



problem is that a physically balanced beam won't turn in the most advantageous direction — that is, into the wind where the least wind resistance would be, along and in the same direction as the boom. Since the wind blows equally on the front and rear at the same time, the boom is at a 90 degree angle to the wind. The result is wheezing, pulling, whistling, and a massive strain on the guys, hardware, mast, boom, tower, and the "whole ball of wax." Now if you will admit to yourself that the whole thing is going to move anyway, then why fight it?

Let's take a positive attitude for a change. Have the wind work with and not against us. By installing a small tail fin on either end of the boom, the antenna will automatically always put its thinnest side, or least resistance into the wind; any material, plywood, plastic (invisible), formica, or any other dielectric will do. It won't effect the radiation pattern in the slightest. If plywood is used, better give it several coats of shellac. Run two "U" bolts through it with double nuts and oversized flat washers on all sides. Then when the big blow is over you can reorient and recalibrate the rotor box (which would have to be done anyway).

By now you have probably discovered you can't rotate the array during a wind storm anyway, as the whole thing slips 90 degrees against the wind.

Don't use too big a fin. We only want the big winds to move it, and not the small breezes that the meshed gears could normally contain anyway. With the beam facing into the wind and not against it perhaps you have prevented complete collapse of the entire structure.

The photos show my six meter twelve element "home brew" beam with a commercial eight element two meter antenna above. While not the ideal situation, it will do until I can afford a rotor with a built-in mechanical brake.

Greetings, You Have Been Selected

Ah, a nice day — for May in St. Louis at least. Let's see, things to do . . . Well, I think I'll check the old mail box and see if any of those 85%'ers might have had a change of heart and decided to QSL. The guys in the States that are hardest to work on good old six meters seem to display this propensity of not . . . HELLO? What's this? A notice from the U.S. Post Office or Postal Service (you know, the outfit that cancels those pretty QSL's on BOTH sides). A registered letter awaits me.

(Sigh) . . . we'll just jump in the faithful Jeep and drive down to the Post Office.

Upon identifying myself (all the way back to my ancestors on the Mayflower), a very official looking letter is placed into my determined grasp. Official indeed! U.S. Government markings all over the thing. The last time I saw anything this official, it said something about "Greetings." They wouldn't, I mean they couldn't, but, but I'm too old. Must settle down and open the envelope. After all, I just signed Lord knows what to get it. And get it, I did. After fourteen years as a Technician, a happy, fun-loving (if not slightly pudgy), died-in-the-wool Technician, I received the F.C.C.'s version of "Greetings," a recall.

The day following the receipt of this doomsday message is pretty hazy in my memory but the XYL later told me that for the most part, I was hysterical

and incoherent. At times like these, we non-drinkers are severely handicapped. This will not do. Must pull myself together and face the situation calmly and cooly and think of some flim-flam excuse to stall them off until the next time they swoop down on St. Louis. Yeah, that's it, that will give me an extra three months to get it together. Let's see — dit-da is "A," dah-dit-dit-dit is "B" or "D?" Code records. Gotta have code records not to mention theory books. Gotta find out about those little trans-sa-ma------- goodies that replaced tubes. I constantly had to repel the urge to send in the ticket and slink off somewhere and slash my wrists. Every idea ever conceived to aid in learning and improving the code was considered. Nothing was overlooked. The depths of my panic knew no bounds even to the point of recording several code lessons on cassettes, putting the cassette on a timer and having it try to probe my sub-conscious during my sleep. As weird as this sounds, I really believe it helped. At least, it got me to the point that I had enough nerve to listen to the forty meter Novices. Listen with what? A quick call to my buddy, Bill WA0KBZ who is a true mercenary's mercenary, and I was all fixed up with an Allied AX-190 receiver and a greatly deflated wallet.

Disregarding two of my original ideas of sending in the ticket and the flim-flam excuse, I attacked with all the determination of the chief boiler stoker on the Titanic. I thought it was a good thing they extended the Novice ticket to two years and I was thoroughly convinced that it would take that long to complete a QSO of any length. It wasn't easy but after about two weeks, I could make sense out of that noise. I became fanatical. Working shift work, I was able to copy for three to four, and sometimes five hours a day and go to work to relax.

WA0TXV Bob sicked me on to W1AW. After a few nights of people taking their hate out on the League by getting a hundred or so cycles to the side and CQ'ing and QRM'ing, I deemed that a good CW filter was in order. In my neophyte stages, I didn't realize that the AX-190 and the CW filter only represented the beginning of a never-ending outlay of money.

For the following several days, W1AW was copied and recorded through my new (and expensive) CW filter. The recorded tapes were secreted away like a starving squirrel that anticipated yet harder times. Finally, good old midnight shift

came to pass and as this time of year is a slow period in my line of work, the theory books and previously secreted tapes accompanied me to work. It took about eight minutes of dit-dah's and I was up to my bellybutton in disgruntled fellow workers. They had suffered with my "weird" hobby in the form of boring conversation for the last several years but this was the limit. Being the kind of fellow who takes friendly suggestions to heart, I decided to appease this potential lynch mob and suffer silently with an earphone. Now I have nothing against any ethnic group or nationality but I just can't understand what the Japanese had in mind when they contrived those nasty little earplugs. Why didn't they design one that would fit the ear?

The thing was starting to take shape — transistors, formulas, chokes, taps and all the accoutrements of "wireless" started to make a little sense. The code was coming along swimmingly. Visions of a General License with my call kept popping into my code-weary mind and on every occasion that I struggled through the ominous 13 wpm barrier, I sort of giggled inside. The first instincts of mere survival gave way to a more human feeling of REVENGE! Challenge my integrity will they! I had ambitions! I kept thinking of the mean old F.C.C. examiner grovelling in disbelief — not only passing the Tech, but WOWing him with my new-found CW prowess.

The day of decision was finally upon me. I was to be at the examination station at 9:00 a.m. At 5:00 a.m., my eyes popped open and I eagerly got in the proverbial last minute of CW and theory study. At 8:00 a.m. I departed the studios of radio-free K0CBA and plunged forward into the St. Louis sunshine — a raging downpour! The weather should have made me reconsider my idea of a flim-flam excuse. However, with the well wishes of the XYL, the "go get-em" of the local six meter gang and a few well-meaning threats of, "You had better pass because we can't take any more" from the guys at work, I continued my sojourn.

Upon arrival at the Federal Building, I couldn't find a place to park. Another bad omen? Nonsense, I forged ahead as if I had good sense and finally located a parking meter, but it was a "One Hour Only" parking meter. At this point, confronted with the prospects of failure in the amateur fraternity, a tick-

et (St. Louis Police Department type), and possibly a humongous tow bill, all I could do was to hum, "Cast your fate to the wind" and fight back my own downpour which was about to trickle from my eyes and go in and scope out the situation. I was a half-hour early and the examination room was still locked so I tried to make conversation with the other hyper-tension stricken people that had gathered under the "NO STANDING IN HALL" sign. My mind briefly contemplated the Governmental wisdom behind the placing of that sign and the fact that there wasn't a chair or waiting room to be seen from horizon to horizon.

A young lad who was observed in the corner with bloodless white knuckles, frantically scanning his license manual, would look toward heaven, mumble to himself and then would appear to "chew" a bit of the book's ragged corner. I got to talking to a fellow who introduced himself as "Dale WN0 something or other" and he mentioned that the code was a snap but he was a bit concerned about the theory. I thought that was a strange thing for him to say. If he had his wits about him, he surely would have been terrified of both elements, just as I was. I quickly ran through the alphabet in my mind. A poor choice of pastimes, and I suddenly realized that I couldn't recognize my own call. I reached in my pocket for a pen and a piece of paper. A note attached to the door, proclaiming that I had been carried away by a roving band of gypsies and would probably be released unharmed in time to take the test in three months, would surely tug at the examiner's heart and he would reschedule me for the next time in town. Surely a fellow couldn't be held accountable under such circumstances. I started to compose the note a bit too late as the door opened and there stood the examiner. He foolishly assumed that because I was closest to the door that I was the most anxious. He asked me what Class I was here for as he relieved me of my F.C.C. provided "610" and "examination appointment." Before I could stutter out an answer, he looked up from my papers and said, "A Tech recall, huh! "Sit over there and fill this out." I took the paper he gave me and wobbled over to the indicated seat. Any composure that had remained with me in the hall, ran down my leg. As the others filed in, he looked at them but always seemed to fire a glance my

way, or so it seemed. I consoled myself that he wasn't really a bad fellow who had a personal desire to snatch my ticket, and that he probably just learned to look at people like that from when he headed up a concentration camp.

As he passed by me, handing out the paper for the 13 wpm test, I said, "Excuse me, sir, could I have a try at it?" With a patronizing smile, he gave it to me and proceeded with his tasks. After several eternities, the silence which heretofore was only interrupted by nervous laughter, pencils thumping on desks and an occasional drop of perspiration rolling off my proboscis and hitting my paper, was broken by an ear-splitting, "Is everyone ready?" After 6 v's which gave me no trouble, I realized that this was it! I have a real knack for being able to size up a situation. I got the first few words out but then a miss, and another, then a few more words, then the misses again. After the machine sent ar, I started to try to do some fills. No dice. The papers were gone as quickly as they had come. "You may all step into the hall while the papers are checked." After a few minutes of staring at the "No Standing In The Hall" sign, I went into the room to watch. I saw a booklet on his desk which I think was entitled, "The stacking of papers on a desk so no one can see if they passed" and quietly left the room. I amused myself by running the six hundred yard dash to my parking meter, narrowly escaping the clutches of the law which I considered to be a good omen. I walked into the Federal Building as if nothing happened and then it dawned on me that it was raining and I was soaked. So much for that good omen.

Upon being reseated with the others, the "thumbs up — thumbs down" session started. I was in the latter, however, all was not lost. I squirrelled through enough for 5 wpm and so it was on to the theory. Osmosis is a fact and I had inadvertently soaked up enough that I made the theory in pretty fine style.

After the whole thing was just a bitter memory from the earlier part of the day, I became even more obsessed with getting my "Big Ticket." The levity of the situation only now comes to light as I gaze upon my shiny new "Advanced License."

The story doesn't really end here. After all, in September, I'll have my "Year In" and then I'll have a shot at the "Biggest Ticket." ■

Save Money on Coax

If money is worth anything to you, then the easiest way to save it is to quit using RG8 for anything lower in frequency than 21 MHz, and shorter than 100 feet, regardless of power unless you are running more than the legal limit.

If you are using a dipole, which is about 72 Ohms, and feeding it with RG8, you have an SWR of 1.5:1. If you fed it with RG59, the SWR would be 1:1 at resonance. The loss in RG8 at 1:1.5 would be a little more than .7 dB, and the loss in RG59 would be about 1.6 dB at 21 MHz. The difference would be barely noticeable on the air, even with careful listening. At 7 MHz, the difference would be about .45 dB, and not even discernable.

The power handling ability of RG59 at 20 MHz is 860 watts, and if you use foam coax it is about 1100 watts of steady RF. This is enough for any legal amplifier, and of course for use barefoot there is absolutely no need for RG8, even for a 750 watt PEP transceiver.

The most ridiculous of all, of course, is the ham who insists on running RG8 in a mobile. Many of them seem to feel that with a mobile you need all you can get, but RG8 is harder to handle, and no one could possibly hear the difference between RG8 and 58 or 59, with only 20 feet of line.

If you are running a 50 Ohm antenna, there is some reason to use RG58 instead of RG59, but not much. The SWR will be 1.5:1 but the greater loss in RG58 will almost equal that due to the mismatch, even at 21 MHz.

Oddly enough, there is a good reason why in some cases RG8 has its advantages. The reason is that you can't bend it at sharp angles. Running coax with sharp bends is not good for transmission, and since RG8 won't bend in square corners, it is better at very high frequencies. Wouldn't it be just as easy, and cheaper, to just make sure that your bends are gradual, rather than pay the extra cost?

Many hams buy surplus RG8 and save money, they say. If you do that you had better check the loss in what you buy. All loss tables refer to NEW coax, as you will find out if you measure it. ■

How to Pass Exams

When I went to school many years ago, I was very lax about studying, but I had great interest in the subjects I took. While in class, I was careful to observe the teacher and try to understand what she was saying. I was the son of a construction engineer, and had traveled so much that I had never been to school in the same state for two consecutive years. Thus I was a sort of loner in the schools because I didn't know any of the kids from previous years. However, I was also a sort of curiosity. Kids used to want to hear about Puerto Rico, Montana, and New York City — three places where I lived at ages 6, 5 and 4.

I used to read a lot and at age 8, I began going to the library every afternoon to borrow a book to read lying in the library yard, and taking it in when the library was ready to close or I had to go home to eat. As a result I rather immersed myself in the book, as if I had really experienced what I read. If anyone asked me about anything I had read, I felt right at home and could answer anything.

I did the same with school books because I had developed a great desire to learn. When the time came for exams, I had no trouble because it was like someone asking me what had happened on a trip.

I took a civil service exam for postal clerk during the depression, and although the exam ran from 8:00 a.m. until 5:00 p.m., I was through at 9:30 a.m. The examiner asked if I was sure I was through. I said I had put down all I knew and there was no use trying to put down things I didn't know.

When the grades came out, I tied with another man for top place. By that time I had another job so they gave the appointment to him. There were 300 who took the exam.

When I was working at the City of Dayton Engineering Department, an exam came up for transitman, which meant that I could move up a grade. It also was an 8:00 a.m. to 5:00 p.m. exam.

I took the exam and one of the questions was a "Cut and Fill" question. This meant that you had to draw a cross section of a road and make squares to represent cubic feet of dirt. Then you had to compute the cubic feet of dirt in the high spots and place them in the low spots. This was a laborious job and could take a couple of hours. I noticed that the question was #3c. There were 10 questions so that meant that question #3 was 10%. This meant that #3c was only 3⅓%. I thought — "That's not worth the trouble." So I finished the rest of the exam and left at 9:45 a.m.

When I gave the paper to the examiner, he said, "Are you satisfied? There is plenty of time left." I said I was. "Did you get that Cut and Fill problem?" I replied softly, "Are you kidding — for 3%?" He laughed, and said, "We wondered if anyone would notice that." I was again top grade and got the appointment. When we discussed it next day, the chief of the department said, "It is just as important to know *when* to do something as how to *do* it."

I have since passed difficult radio exams the same way. Most of them now are multiple choices and I never took more than 45 minutes for one. I have been studying psychology for many years, and I combined the two. After several years study I have come up with this method. I am sure that it will help many of my readers, but to be helped, you must accept what I say without blocking its result by not believing in it.

Your mind is divided into two parts — the conscious mind and the subconscious. Everything you know, everything you have ever seen or heard — is in your subconscious. A good hypnotist can bring out any or all of what is in your vast subconscious mind. The question is — how do YOU do it. Very simply, by being your own hypnotist!

It sounds simple, but it is not quite as simple as it sounds. Before it really works, you have to have a way to get at what you want without having to delve through your entire lifetime to find it.

The first requisite is that when you store information, you classify it in a

way that you can find it. The best way to do this is the same way I studied when I went to school. You must *understand* what you are learning. If the teacher or professor goes by anything you don't completely understand, stop him at once, and make him explain it. In the first place it is your right to demand this, but best of all, if you are sincere, you will please the teacher. A good teacher is always pleased when his pupils are interested in what he is teaching. When you understand it, it goes in your mind as a unit, and is much more easily recalled than if you were to memorize a lot of disconnected facts and try to recall them.

Your mind is made up of a lot of nerve cells called neurons. They are all almost connected together. They have little gaps separating them and when a neuron is activated, a little electric charge discharges across the gap. This gap is called a synapse. When the discharge takes place a number of times, the resistance decreases and the gap is jumped more easily. This is "training."

Advertisers use this to train your mind to think of their product. They say that it takes 36 repetitions to fix the path. Did you ever smell something cooking and have a vision come to your mind of a kitchen back in your childhood, or smell a perfume and have it bring back a romantic memory? The same principle applies to the recall of information. When you see a question on your exam paper, you want the answer to come into view.

I was president of a training film company for thirty years, and I used one primary rule of learning. You must accept whatever the teacher or books say without reservation for rapid learning. Pick your authority with care, but once you do that, then never question anything you read, for the present, anyway. This way your mind is very receptive to learning. If you begin to question anything, you skim off the information at your present level of knowledge, and therefore learn nothing. Furthermore, by your negative attitude you slow the learning process. If you accept everything, you will at least know more than you did before, though you may learn a few things which you may later wish to change.

I had to learn in a day or two everything my customer had learned in twenty or thirty years. I did this

by accepting everything he said as if it were being poured into my mind with a funnel. It will amaze you once you try it. If you learn under relaxation, it will further intensify the learning process greatly.

I once had a film writer ask me to teach him everything about film editing in one day, as he had a job interview in Washington the next day. We both worked in the Motion Picture Divison of Wright Field. I was chief of the editing branch. I explained about the theory of funnelling knowledge into the mind and relaxation, and he understood. I spent the day telling him everything I knew about editing. He went to Washington, got the job, and in several months became the Producer of all Training Films for the National Labor Organization.

Some people learn sound better than sight, and I am one of them. If I want to remember a date, I say it aloud, and remember how it sounded.

An excellent way for "Audio" people to learn is to read the information into a tape recorder, and then play it back under relaxation. This also works for the "Visual" people, who remember what they *read*.

In fact, reading what you want to learn into a tape recorder and playing it back under relaxation is about the best way for anyone to learn anything.

At college, many students take a tape recorder to classes they are unable to attend either because of illness or because they have another conflicting class at the same time. They put the recorder on their desk, and leave, and pick it up after class. Another student will turn it on or off for them. Thus they have the entire class discussion for study when they review.

Now for learning directly with your subconscious, by-passing the conscious mind entirely. This is very good for subjects which depend on instantaneous decisions, such as taste in decoration or dress. It is also useful for touch typing, and I will give you a spectacular example.

During World War II, in North Africa, the U.S. Army trained African natives to type telegraph code directly from the headphones to the typewriter. Simple, you say? Except for the fact that none of the natives could speak English or even read it. They were taught that dot dash meant A, and so on, until they could copy at a high rate of speed without having the slightest idea what they were hearing or writing.

As you may have observed, a good telegraph operator can talk to you while he is copying from a telegraph wire at high speed because he is not using his conscious mind at all.

You can learn composition in painting or judging art and the like the same way. To explain with your conscious mind why a composition is good is very difficult to do, and hard to learn. But by looking only at good art your subconscious can learn extremely fast.

My wife and I used to go on automobile trips, and she being very much interested in architecture, would point out houses and tell me what had been changed on the house, and how it should look. These were classic old homes which had been "modernized" by having small paned windows replaced with large glass and having parts removed and added. I had no education in architecture and decided to learn.

How to learn quickly — that was the question. Then I had an idea. I thought of the bank clerk I had once been, and how a teller could pick up a counterfeit bill at a glance from among many good bills. The reason, of course, was that he was accustomed to looking at good bills. I decided to use this principle, but with greatly expanded fields. I got several architectural magazines from the library, and leafed through them. Then I began to look at news stands, and while I was waiting in advertising offices. I often had to call on these offices for work, and they all had magazines with beautiful homes. The following summer, when we went on vacation, my wife mentioned a house we were passing. I quickly glanced and said, "Yes, they have added dormers and changed the entrance." She was surprised, and asked how I knew. I said that I had been studying architecture.

Let's try to bring this into your field. Do you identify cars readily? Or are you familiar with cameras? If you are a connoisseur of high-priced cameras, can't you tell if someone puts a cheap one with them? The reason is that you have unconsciously been mentally photographing what you see and it is retained in your subconscious mind.

Now comes the distinction. When you study day by day, you are studying and reciting with your conscious mind. But your conscious mind can only handle a limited amount of information, so the work is given you in amounts you can handle.

There is no limit to the amount of information your subconscious mind can handle. With a little practice you can learn to use it.

You've been self-hypnotized many times. You have entered hypnosis spontaneously literally hundreds or even thousands of times, depending on your age. We all slip into a trance at times every day of our lives, though such situations are not labeled hypnosis.

Dr. Griffith Williams, of Rutgers University, has written of these spontaneous states in an article in Experimental Hypnosis (New York: MacMillan, LeCron editor). Daydreaming is nothing but a state of hypnosis, perhaps light, sometimes deep. When we concentrate intently on anything, such as reading a book, watching a motion picture or TV program, or even on our work, we tend to slip into a trance. It is even probable, as Estabrooks has pointed out, that we do so whenever we experience a strong emotion, such as fear or anger.

How Hypnosis Feels

A hypnotized person is never unconscious. He knows what is going on all around him. He can even walk or talk while under hypnosis.

Only a light degree of hypnosis is needed for our program. In this stage there is no specific sensation of being hypnotized. All you feel is a listlessness and great relaxation. After you have followed this program for a week or so you can test yourself by telling your finger to feel tingly. If it does, it means that you are hypnotized. If it does not, either you are skeptical or have not kept at it long enough.

Incidentally, you can use this method to help you when you are studying, by letting you concentrate when there are many things going on around you.

If you like, you can record the words you are going to say, in a low monotonous voice, or you can even read them to yourself aloud or silently. It may take a little longer, but it may be easier for you.

How To Hypnotize Yourself

1. Select a place or room in your home where you can be reasonably sure that you will not be distracted by the telephone or other unnecessary noises or interruptions. It will help to draw the blinds or subdue the lights. Soft music often puts some people more quickly into a state of hypnotic relaxation. You may want to experiment by selecting a type of music that is soothing and

conducive to "sleep-like" relaxation.

2. Lie down on a bed or comfortable couch or semi-reclining chair, placing your feet on a hassock or some other firm object serving the same purpose. Loosen all tight clothes.

3. Take three deep breaths. Breathe deeply and slowly.

4. Close your eyes.

5. Say to yourself, as if to another person (your subconscious mind):

"You are going to relax all the muscles of your body ... starting from your head to your feet ... The muscles of your face and neck are relaxing ... The muscles of your shoulders and chest are relaxed ... You're beginning to feel free of all muscle tension ... Your arms feel limp and relaxed ... The muscles of your thighs, legs and feet are relaxed. As you breathe deeply and slowly, your entire body is completely relaxed. You feel calm and relaxed all over."

Rapid Method Of Hypnosis

After you have practiced the prescribed method of relaxing yourself each day for more than a week, and you are satisfied that you are able to relax completely, you are ready to use a more rapid method of autorelaxation.

Say to yourself, "You are going into relaxation at the count of three. One - two - three."

Rapid relaxation can also be achieved in the waking state. You give yourself the count and quickly experience a relaxed feeling throughout your body. Your mind suddenly becomes relaxed and receptive to suggestions. You suggest to yourself that hereafter whenever you use the work "Relax," the relaxation will occur instantly. If you are walking or sitting, you naturally are going to keep your eyes open. You tell yourself that you are completely aware of your surroundings at all times, and that you are in full control of your mind, except that you are in a state of self-induced relaxation as well as a state of increased receptivity to self-given suggestions. Once you have practiced this rapid method of hypnotically induced relaxation, you are ready now to make good use of your subconscious mind by giving it suggestions. Your subconscious mind will do for you what you want it to do. By repeating and repeating a given suggestion to your subconscious mind, you will accomplish your objective.

Twenty percent of the population are extremely easy to hypnotize. These are the ones who enjoyed the play, *Harvey*, with the big "invisible" rabbit.

They could actually see him. They are the people who enjoy eating in restaurants where the menu and signs tell you how wonderful the food is and the fabulous taste of everything you eat. My sister is one of these. She enjoys everything if the signs tell her she will. I am of the 20 percent which are hard to hypnotize. No matter what the menu says, if the food is not up to standard, nothing on the menu can make me enjoy it.

The second 20 percent are relatively easy to hypnotize, but cannot have hallucinations. I believe that these two groups, of 40 percent, are the ones who will benefit most from this folio. They are most likely to be afraid of examinations, and pay too much attention to remarks in class and elsewhere about how hard the exams are.

By all means do not tell anyone you are studying this article. Many of them will ridicule it, either because they don't understand it or because they want to downgrade your ability to make themselves feel good. These negative comments and influences will cancel part of the positive influences I am trying to give you, if you are suggestible, and cause you to fail. You MUST think positive — that you KNOW that you will pass, or this is wasted.

Remember that under hypnosis you could recall everything you had seen or heard all your life? If you were to pass a man on the street and glance at him, a hypnotist could have you recall every detail of his appearance. You could tell what sort of socks and tie he wore, the color of his eyes, and every detail of his dress. The same thing happens when you look at a book, or a newspaper. If you read an item in a newspaper, you are also scanning all the other material on the page. If there is an item about a red-haired man committing a murder, you may find that you have a feeling against red-headed men, and you will never know why.

So, now let's glance at each page of our book which deals with the subject of our examination, deliberately turning the pages slowly and glancing at the whole page. Do not try to read anything on the page, just "microfilm" it with your eyes. This will put the entire subject in close proximity with each part of it, so when you go to recall it, you can quickly scan it for your answer. I use the word scan, but the speed of scanning is faster than any computer.

It is absolutely essential that you believe you are

going to pass the examination. When I go into an examination room, I KNOW I am going to pass. It never even occurs to me that I would fail. I don't always make perfect grades, but I always pass. Any feeling that there is any doubt about it tends to inhibit your recall. If anyone asks if you are worried, just smile and say, "No."

Each night when you go to bed, give yourself the key word, "Relax," and say, "When I wake up I will feel wonderful, and full of energy, and have confidence that I will pass my exam." When you go to take your exam, you will know that you have everything you need to know in your mind, and all you have to do is say, "Relax," and tell your subconscious to give you the answers.

After you have completed giving yourself post-hypnotic suggestion, either in the sleep-like or waking state, you can tell yourself that at the slow count of ten, you will rouse yourself from the self-hypnotic state with a feeling of emotional well-being, inspired by the conviction that you are going to benefit immensely from the application of the particular suggestions you have given yourself.

When you start, take each question, read it carefully, watching for tricky wording. Be sure you know exactly what the question is. Then look at the multiple choices. If you cannot answer a question at once, go on to the next but put a little mark at the left of the question. Don't waste time now. This is one of the big mistakes most people make. They get stuck on something they don't know and don't have enough time at the end to answer the last questions.

Go ahead and answer all the questions you can, and then go back and pick out the ones you could not answer. First, try to eliminate the two impossible answers. That will leave three. Two of them will look like the right answer, probably. Guess on one if you don't know the answer. Do NOT leave any question with NO answer. All examinations are designed to allow for guessing. If you were to guess at all 100 questions, you would likely get a grade of 20%. If you can eliminate the two impossible answers and guess out of the three left, you will get one of three right.

Usually 70% is passing. This means that you can have 30 questions out of a hundred that you can miss. If you guess wisely, you can probably guess ten of the thirty right. This would give you 80%.

All of this assumes that

you make a serious effort to study the subject thoroughly. It would take first class hypnosis for you to glance through a strange book and pass an exam, but with the right training, you could probably do it.

For Radio License Exams

Now for the code part of the exam. The same rules apply here. You must go in with the conviction that you will pass. You will have five minutes to copy. Do not copy anything for at least a minute, perhaps two. Get the feel of what they are sending. Just get used to the sound and the speed. Remember, you only need one minute of solid copy. Pick a pause and start in. Copy the best you can for about a minute and a half. Then stop and look back over your copy. You may find you have made an "e" look like an "i." Correct it. Just try to fix any uncertain letters that may make the examiner wonder what you meant. Tell your subconscious to time you.

Before you go to take the exam, try timing yourself by relaxing and see how close you come. I can come to within a few seconds this way. Practice a little. Starting to copy when the code starts coming is very unsettling. You are surprised by the echo in the room, or the charcter of the sending, and at the same time trying to put down what you are reading.

Use the hypnosis instructions when you are learning the code. A well known hypnotist found that it was possible to distort time to the extent that you could practice listening on the violin in ten seconds what should take ten minutes to study. This would mean that you could, under hypnosis, copy five words a second instead of five words a minute, and this would mean reading 300 words per minute instead of five. Think about that for a while. ■

County Hunting

Remember how you counted the days waiting for your ticket to finally arrive? Recall the first time you fired up your rig... your first QSO...your first real DX...those elusive last states and countries you needed for the WAS and DXCC you wanted so badly? When you think about it, if you're like most of us, you constantly set goals for yourself. Maybe it's making the DX Honor Roll or the BPL Medallion or coming in first in the Sweepstakes or just being the best operator you can. Whatever the goal, whether you achieve it or not, it eventually loses its importance. Normally you just set a new goal. But, sometimes there just doesn't seem to be anything worth getting excited about; hamming isn't any fun anymore. Well, if you're looking for a real challenge, something that will provide lots of competition, require good operating skills and endurance, yet provide numerous rewards and lots of fun, you've found it! It's called county hunting.

County hunting is kind of like working all states 61 or 62 times over, or if you prefer, like making the DX Honor Roll ten times. All you have to do is work a station in each and every one of the 3076 counties evenly distributed throughout the United States. Sound interesting? It's quite a challenge. Only about 120 hams have managed to do it. But don't let that discourage you because that exclusive group includes a ZL1 and a G4. And if they could do it with the propagation we've been having, anybody can do it.

Of course, achieving a goal isn't much fun if you don't have something tangible to show for your efforts. Fortunately, there are two rather attractive awards being offered by well known organizations to those who manage the feat. Both award programs begin with an initial requirement of several hundred counties, for which you receive large certificates you'll be proud to display in your shack. As you add more counties to your total, you receive special seals to be applied to your certificates. Finally, when you finish them all, you receive beautiful wall plaques.

While the two award programs differ in some important details, both permit you to claim every contact you ever made, or ever will make regardless of your call or QTH at the time. The only requirement is, of course, some proof that the contact was made. But more about the nitty-gritty later. If you're like most hams, you've got a shoebox full of old QSL cards and old log books buried in a closet somewhere. If you do, you're off to a good start. But whether you want to use those old contacts or start from scratch, you're

going to need a reliable means of determining in just what county each station you work resides. Of course, if he tells you or has it printed on his QSL card, there's no problem. This isn't the usual situation though. That's why sooner or later you'll want to get your hands on the "Directory of Post Offices", available from the Government Printing Office under the stock number 3900-00242 for $4.25. This marvelous publication lists every Post Office in the U.S. as well as the county in which it is located.

The Rewards

Once you've got yourself squared away, you'll want to decide which of the two available awards you want to go after. There is, of course, nothing to prevent you from going after both of them simultaneously — as long as you keep the different requirements for each in mind. The better known of the two is the United States of America Counties Award (USA-CA) sponsored by CQ *Magazine*. This certificate is printed in four colors on white parchment-like stock measuring 14 inches wide by 22½ inches high. The design features full-color illustrations of all 50 state flags. You can get it by submitting proof of having had two-way contacts with amateur stations in 500 counties. If you qualify and so desire, you can have your certificate endorsed for all one band, all one mode, and/or all mobile contacts. There is no minimum signal report required. You must, however, have QSL cards in your possession for each county claimed. But you don't have to submit them with your application. Certification by two General or higher class hams is sufficient. If by chance you contacted a mobile station that just happened to be parked on a county line, you may claim all the counties in which a piece of the mobile resided. It's sort of like getting two or more for the price of one, but the mobile operator must indicate clearly on the QSL which counties may be claimed.

To apply for this award, you must use a special record book available for $1.00 from the sponsor. Complete rules and procedures for the awards are contained in this record book. After the initial 500 counties have been worked, you can submit additional 500 county lists for the higher class seals. These higher class applications can be made using the record books, but a self-prepared list is acceptable.

The other award is the United States County

Hunter's Award (USCHA) sponsored by the Certificate Hunter's Club. This certificate is printed in black on an off-white parchment-like stock measuring 22½ inches wide by 17½'' high. The design features an outline map of the U.S. with each county defined and labeled. It is intended that as the county hunter moves from class to class in his quest for the magic 3076, he will color in each new group of counties in a different color. The end effect is a mosaic-like color map of the U.S. You can get it by submitting proof of having had two-way contacts with amateur stations in 300 counties. However, U.S. hams must include at least one county from each of the 50 states. In other words, you've got to work all states before you can get started on this one. DX stations, though, get a break. They need only include counties from 30 states. Any contact may be claimed, but at least a 3x3 report each way is required. You don't need QSL cards, but your log must contain all the required data, and two General or higher class hams must certify it's all there. If by chance you should work a mobile station that just happens to be parked on a county line, you must choose which of the counties you want to claim. If you need all the counties involved, you must establish separate contacts for each of them. Sure it's crazy, but that's the rule.

To apply for this award, you must use a special record form set available at 3/$1.00 from Cliff Evans K6BX. Complete rules and procedures are included in the form. After the initial 300 counties have been worked, you can submit additional 300 county groups for higher class seals, but you must use the special form set for each application.

Once you've decided which of the two awards you want, or decide to go after both of them, you're ready to go. You'll very quickly discover, however, why only 120 or so hams managed it. For one thing, there are quite a few counties in this country that contain no active hams. Even when there are a few active hams in a county, it may still be out of your reach because those hams operate on bands or use modes you don't. But, if you're fairly active, take advantage of state QSO parties and similar activities, check into state and regional traffic nets, and participate in the Field Day contest, you stand a very good chance of nailing down a couple thousand counties in two or three years. After that, they'll come very, very slowly. Under normal circumstances, it should take you around ten years to finish

up. Why? Just think what the odds must be against your randomly tuning around one day and finding a mobile calling CQ from the one county in Montana or Wyoming or wherever you need.

The Nets — Or How To Cut It Down To Just Four or Five Years!

Obviously there has to be a better way — and that way is the county hunters' net. Actually there are several nets operating in the CW and SSB segments of 20, 40 and 80. The best known and most popular of the nets is the 20 meter Independent County Hunters' Net (ICHN) operating daily at 14.337 MHz. It normally starts up between 14:00 and 15:00 UTC and continues in operation until the band folds. During the summer months a 40 meter ICHN operates at 7.237 MHz. This net starts up around 01:00 UTC and continues in operation until the last county hunter pulls the switch. Both of these nets are truly independent, having no affiliation with any organization and following no formal operating procedures. Though both will accept emergency traffic and render what assistance they can, they exist primarily to get county hunters together with mobile stations.

Another net that plays an important role in county hunting is the CHC-FHC Service Net that meets daily on 3.943 MHz. It usually starts up around 8:00 pm local time and runs past midnight. Depending on the season of the year and propagation conditions, the net is restricted to an area of only a few hundred miles diameter, or may operate coast-to-coast. This net, as the name implies, is a function of the Certificate Hunter's Club. Although it will accept emergency and time-controlled traffic, its prime function is to aid amateurs in their quest for the thousands and thousands of certificates and awards available to the ham community. CHC membership is not required; everyone is welcome to check in. However, since only a small portion of the available awards are county oriented, you hear a lot of non-county hunting activity. Nevertheless, at one time or another, just about everyone of the 3076 counties have run on the CHC-FHC net.

It will take you a while to get used to the rather haphazard operations of these nets. Generally, the process begins with a county hunter picking up net control and getting a couple of others to act as relay stations. After getting things going, the net control will put out a "QRZ mobiles" call. Those mobiles on frequency wanting to give out contacts from their coun-

ties then identify themselves and standby. Normally the mobiles are run in the order they are acknowledged by net control, but sometimes the order is adjusted to allow for differing in-county times.

The run itself begins when the net control announces the mobile's callsign and county, has it repeated by the relay stations, and gives the mobile a starting time in UTC. The mobile then puts out a "QRZ such-and-such county, such-and-such state". That's when all hell breaks loose! Unlike the more sophisticated nets, the county hunters' nets have no calling order — it's every ham for himself, just like a DX pile up. I wonder how many hams have stumbled across these pile ups only to go away mumbling to themselves when they discovered the fuss was over a W6 somewhere in California. Adding to the fun is the usual 20-over splatter and an assortment of carriers as well as a group of lids whose total ham activity seems to be tuning up and saying "hello test" on net frequencies. No one knows why, but it is a fact that more of these mental midgets prefer to do their things on the county hunters' nets than on any other. Even with the QRM, the mobile operators do an exceptionally fine job of making contacts. When propagation makes contacts difficult, other stations on the net will help you by relaying the mobile's call, county, state and any other needed information. But, you've got to get your signal reports across without help from anyone. If you can't exchange the reports by yourself, you've got no contact. However, since signal strength can vary from minute to minute, you'll get a second chance at the end of the run if time permits.

QSL Cards — How To Get Them

Getting confirmations is a problem that plagues all aspects of ham radio. Of course, depending on which award you want, you may not need confirmations. But, if you do want them, you're going to have to go get them. You can't just sit back and wait for them to magically appear in your mailbox.

One method that works fairly well with fixed stations is to include with your own QSL a self-addressed, stamped envelope (SASE). Of course, you're still depending on the other station having QSL cards, and being willing to take the time to look up your contact in his logbook. A better method, and the only one to use

with mobile stations, is to prepare a QSL *from the other station to yourself*. Since your purpose is to get confirmations, not pretty multi-color cards to decorate your shack, you can use a simple 3x5 index card. All you have to do is list all the required data: the other station's callsign, date and time of QSO, frequency and mode, signal report (the one he gave you), the county(s) and state(s) he was in, and clearly indicate where he is to sign if he agrees with your data. If you prefer, you can use commercially printed reply cards available from WA2AMM, K7LTV, K9EMV and others. Put your name, address and return postage on the other side and you're in business.

The Bureaus

Considering that you must pay letter postage to the other station and postcard postage back to yourself, it's going to cost quite a bit. You can cut the cost down by waiting until you've worked a station numerous times and then putting all the data on a single card. The most economical way to do it, though, is to use one of the two county hunters' QSL bureaus. The best known of these is the Mobile QSL Bureau operated by Dave Manescu W6CCM. This is the bureau the regulars refer to in such phrases as "via the bureau", and "via Charlie Charlie Mike". The bureau will forward your reply cards to the appropriate stations and then return the signed cards to you for just 6 cents each, or 20 for $1.00. Another benefit you derive from using the bureau is the certainty that it has on file the latest QTH of the stations you've worked. Many mobilers provide the bureau with QTH information about portable and extended mobile operations to which you would otherwise have no access. Since it is expected that you will want to send the mobiler your own QSL after the first contact, the bureau will forward these "initial contact" cards free of charge when they accompany your reply cards. With over 500 active county hunter members, the bureau can get you a confirmation for better than 95% of your contacts. Generally speaking, if the bureau can't get you a confirmation, forget it! You can get more information about its operation by sending an SASE to P.O. Box 146, Lakeside CA 92040.

Bob Schmarder WA2AEA operates the other county hunters' QSL bureau, the QSL Clearing House. Its operation is very similar to the

W6CCM bureau, but it offers some additional services. Whereas the W6CCM bureau will accept cards only for contacts made on the 20 and 40 meter ICHN and the 75 meter CHC-FHC nets, the Clearing House will also accept off-net cards, though at a higher price. However, since it has fewer members involved in county hunting, turnaround time is a little longer. For information about this bureau, send an SASE to 4 Pinewood Circle, Corning NY 14830.

MARAC

Although originally founded to provide a meeting place for active mobile operators, the Mobile Amateur Radio Awards Club has evolved into *the* county hunters' organization. Among its activities is the publication of a monthly newsletter which has become the bible of county hunting. You'll find in each edition lists of counties needed by members to finish particular states, planned mobile trip itineraries, notices about county hunter get togethers throughout the country and other information of interest.

Another MARAC activity is the sponsorship of an awards program built around mobile operation, but available to the fixed-station operator as well. The most popular of these awards is the MARAC Last County Award. This award is available to any station, fixed or mobile, that provides another station with its last county in a state. Seals are available for additional last county contacts with other stations. A special plaque is awarded to the station providing the 3076th county to another station. If you qualify, you can apply for these awards yourself. However, as a matter of practice, many stations will apply for the award in your name when you give them their last county in your state. Other awards are available for working a mobile station in each of the 50 states, for working each of the 50 states mobile-to-mobile, for working YLs in various numbers of counties, and for giving out contacts from various numbers of counties and states.

If you decide you want to get into county hunting, membership in MARAC is a wise investment. You can get complete information about MARAC membership, its awards program, suggested operating procedures for use on the nets, sample reply cards and other county hunting information by sending a self addressed large business size (#10) envelope with first class postage for 3 ounces to Bertha Eggert WA4BMC, P.O. Box 6811, Southboro Station, West Palm Beach FL 33405.

CW?

Everything discussed so far relates primarily to phone operation. But if you prefer CW to phone, there's another organization that will interest you: the CW County Hunters' Net (CHN). The CHN operates a net on 3.594 MHz every Monday at 24:00 Z, on 7.055 MHz every Wednesday at 23:00 Z and Sunday at 14:30 Z, and on 14.070 MHz every Saturday at 14:00 and at 20:00 Z. Don't be too surprised if you can't find any activity at these precise times and frequencies. Just look around a little for the "QRZ CHN" call.

While your chances of finding a mobile station calling CQ in the phone bands are pretty good, the same can't be said for the CW bands. Fortunately, many of the CW county hunters are also mobilers and run frequent trips for the net. Since these trips are not necessarily run during scheduled net sessions, you'll want to subscribe to the monthly CHN newsletter. In addition to general county hunting information, the newsletter gives advance notice and itineraries for those special mobile trips. You can get a one-year subscription, and membership in the CHN, by sending $2.00 to Jim Hoffman K1ZFQ, 42 Gresham Street, Milford CT 06462.

The CHN also sponsors a county hunters' award program of interest to both CW and phone operators. The United States of America Counties Award by Call Areas is essentially a step-by-step all counties program. You can get an attractive certificate each time you complete working all the counties in a particular call area. KH6 and KL7 are considered separate call areas for this award. When you've got all twelve awards, you'll get a trophy for your efforts. Other awards include working a mobile station in each county of a particular state, working the same mobile in each county of a particular state, and for giving out as a mobile operator contacts from every county of a particular state. You can get more information about the CHN awards program by sending an SASE to George Levensalor W1DPJ, 399 Buck Street, Bangor ME 04401.

If you want QSLs for your CHN contacts, you can take advantage of the CHN QSL Bureau operated by K1ZFQ. The use of self-prepared reply cards is standard operating procedure on the CW nets too. In exchange for some of your self-addressed stamped envelopes, the bureau will handle all of your initial contact and reply cards for contacts made on the CHN, whether regularly

scheduled net sessions or special mobile trips.

Other Programs

In addition to the awards already mentioned, there are literally thousands of other awards available that you will qualify for in the course of hunting counties. These range from the so-so CHC program to some very high quality awards sponsored by local, state and regional radio clubs and civic organizations. For example, there are awards for working all the counties of a specific state, for working so many stations in a given county, for working counties of the same name in different states, for working so many stations in a given city or in a given radio club, and so on. Although about half of the awards listed are CHC sponsored, there are many worthwhile awards sponsored by independent organizations listed in the CHC's *Directory of Certificates and Awards*, available from K6BX.

If you ask most active county hunters what they most enjoy about it, they will probably tell you it's the many friendships they've made. Eyeball QSOs are commonplace as mobile operators roam the countryside. County hunters living within reasonable distances often visit each other. The annual MARAC National Convention held in July provides an opportunity for hundreds of county hunters to get together for both socializing and problem solving. Frequent "mini" conventions sponsored by local county hunters throughout the country provide a meeting place for those not able to make it to the national convention.

Throughout this discussion I've used the masculine pronoun "he". Don't get the idea, however, that you have to be a male to participate in county hunting. The fact is that you don't even have to be a ham, much less a male ham, to take an active part in county hunting. Both the USA-CA and the US-CHA programs are open to SWLs on a heard basis. Many other awards are also available to the SWL. As far as YLs are concerned, there is probably a higher percentage of YL participation in county hunting than in most other ham activities. Many of the YL county hunters are also active mobilers.

In short, there is something in county hunting for just about everyone. Why not check into the nets and see what it's all about? I think you'll find it both interesting and challenging, and if you're like us, you'll soon be hooked too. ■

99¢ IC BFO

by
Richard L. Price WB5MJT
1506 Morgan Blvd. #106
Harlingen TX 78550

Recently I was approached at the FM station where I work by one of the announcers who wanted to know what the funny voices and pulses he heard on his all-band radio were. After I tried to explain in simple terms that it was CW and SSB and why they sounded that way, he gave a blank look and asked if I could fix his radio so he could understand what they were saying.

Later, after going over a multitude of circuits, all requiring transformers, trimmers, pots, and a good deal more effort than I thought the project deserved, I was reminded of a similar situation involving a 12 year old cousin who wanted an AM wireless mike. The wireless mike used a National LM703 rf i-f amplifier in a simple oscillator circuit. A quick check to a reactance chart and replacement of the original speaker/mike with R2 gave the circuit shown here: a 455 kHz BFO using only a handful of common junk box parts, requiring only about 30 minutes to build.

At the time of this writing the LM703 only cost 99¢ for single units at Radio Shack for tested ICs. The 703 is good to at least 150 MHz and is rated at 200 mW dissipation. With a few minor changes in the tank and elsewhere, this basic circuit can be used as a QRP phone or CW rig, signal source, BFO at frequencies other than 455 kHz, or in other circuits as a LO, etc.

Maybe this will prompt some of us to do some experimenting with the 703 for preamps and such but just as important, I hope the circuit will help some beginners and Novices get their feet wet in building and using home brew gear in their station. ■

Empty State

We call transistors and such solid state now, because they are dense. Small, but solid. They have an almost mythical twin, an empty state device, which is larger in outline – much larger – but so unsubstantial that the working elements if turned edge to, would disappear. By actual rather than apparent volume, or weight, these are negligible, and the container is 99% empty. This *doppelganger* of the solid state device is called a valve, or tube.

Two generations ago, there was practically no solid state device in use and the valve was called upon, singly or in rows, to do any electronic job that had to be done. When solid state became popular, we tried to apply what we knew about valves to them. We were slapped on the wrist by the authorities, who, to a man, pontificated that there was no relationship whatever.

This was obviously an exaggeration, but this fact was apparent only to the uneducated. For the valve certainly had an emitter, a base, and a collector, though they were called by different names.

Solid state elements, such as the transistor, emit electrons – or holes – at ambient temperatures. This requires no heating power at all, but when the ambient temperature falls to zero or below, the transistor stops working. The valve keeps right on working, because the temperature of the emitter is raised to 1,000 degrees Centigrade, or higher. This can be done by a flashlight battery if the emitter is in the form of a filament about one thousandth of an inch thick. Larger elements require more power, of course.

In general, it has escaped notice that the empty state devices can be wired in all the ways that solid state devices can. For instance, for highest gain, there is the grounded emitter. Grounded base gives stability and negative feedback, just as with solid state, and is particularly popular for linear amplifiers. Even grounded collector is used, as with a large device which has a high collector capacity, and so is grounded to permit very high frequency operation. This is encountered only with large water-cooled valves. Valves are also connected in the Darlington mode, but this is more troublesome than with transistors, because of the heater supply. Oh, I almost forgot – grounded collector modes are used with small valves after all, when a low impedance output is desired, as with feeding a long audio transmission line. In this application the valve circuits are called "cathode followers." Isn't this a quaint name?

Input is connected to the base, and output from the cathode. The drop is from the emitter (cathode) through the load resistance to ground. It is called a "cathode follower" because the cathode signal voltage goes up and down along in phase with the grid voltage, and a very little bit less. But while the grid current is extremely low, the cathode current and the signal available is substantial, and the distortion negligible, because of the 100% voltage inverse feedback.

There was a time when hi-fi addicts hated output transformers, claiming that they always changed the signals into something else, not even recognizable. They wanted "OTL," or "Output-Transformer-Less cir-

In general, it has escaped notice that the empty state devices can be wired in all the ways that solid state devices can . . .

cuits," and a number of workers zeroed in on this one.

Think of the cathode follower as a boy in a box. A black box, of course. You feed in power at one end, and get regulated power out the other end. Or you get a substantial signal out, even though the output impedance is low. What you don't know is that the output variations would be wild, except that the boy has a big rheostat in there. When you screw up the output, he unscrews it with his big rheostat, and you don't see the change you would otherwise see. But this holds only over a certain range. When the kid runs out of rheostat range, the output is suddenly as bad as it would have been all along without the kid and his rheostat.

Several amplifiers were built using cathode follower principles. One used four – count them, four UV 211 50 Watt bottles, with a transmitting power supply. It figured an Ampere at 1200 volts, or some such. The amplifier actually did work, and sounded good, but the designer admitted that the thing was highly impractical.

The valve can be operated in any of the classes that transistors or FETs can: A, B, C, D or in between. But while a transistor normally operates class B and has to be forward biased for A operation, the valve needs a negative bias for class A.

All together, a valve base circuit is essentially high impedance, like an FET and most unlike a transistor. The output is lower, usually very much lower, like the FET again, and most unlike the transistor, whose collector impedance is higher than its base impedance. Circuitwise, this is the most important difference between solid state and empty state devices.

Think of the cathode follower as a boy in a box . . .

The empty state device was invented by Lee deForest in 1906. He called it an audion. He wasn't sure how it worked, and neither was anyone else in those days. The electron had been discovered and weighed, but had no more impact on industry than the theories of A. Einstein. Valves were called thermionic up until the middle thirties, just as if ions had anything to do with their operation. Then, suddenly, they were electron tubes.

The AT&T Co. was building a transcontinental line in those days. By using the loading coils of Michael Pupin, and wires as big as your thumb, they had gotten a line that would talk from New York as far as Denver, but no further. A repeater, or two-way amplifier was needed. The directions were separated by means of bridge circuits (called hybrids) and there was the Brown amplifier, which was a head receiver coupled to a carbon transmitter, essentially. This actually worked, but with high distortion and low gain.

Mr. deForest's bulb looked like the answer. AT&T bought rights from the inventor, and Western's tube department – newly organized – improved it. They mounted the bulb on a four-prong, bayonet base to go in a shell-type socket. They retained deForest's double wing pattern, with a grid and a plate on each side of a V filament. The V was supported at the top, and sometimes there were two Vs, or an M filament, called a W.

The filament was made of platinum, coated with oxides of barium and strontium, of which the former was more active. Recently, this kind of coating has been called an N-type semiconductor, since it emits electrons. Tungsten and thoriated filaments also emit, but there is nothing semi about their conduction, so the concept doesn't help much. The coating is, however, up to a hundred times more emissive than the others. It was invented by Wehnelt, in Germany, about 1902 or 1903, before the audion itself.

Now AT&T could extend their transcontinental line to the coast.

The repeater tubes looked very much like the WW I "VT-2" and were made and used up until the middle thirties. They were rated at 50,000 hours life.

The device in the photo is a Moorhead Soft Detector, meaning that it contained a trace of gas. It dates back before 1920, and in those days it was still thought that a sensitive detector required the ionizing feature. The theory was that you critically adjusted collector voltage, emitter temperature and base leak so that the device was barely beginning to ionize. Then a signal would come along and push it over the edge, and the collector, or "space" current would increase sharply. The VT-1, the receiving valve in WW I, was also soft, for the same reason, but was used at low voltages as an audio amplifier as well.

The Moorheads included two other types: an amplifier and an oscillator, or transmitting tube. The last was called "The Golden Tube," which could be due to the gettering employed. It is my belief that these tubes, together with the UV 200, 201 and 202, had a smear of phosphorous pentoxide brushed on the plate. Over a long period of time, this would be evaporated and a molecular layer of phosphorus, or its compound, would be uniformly distributed over the glass. This gave it a beautiful golden color. I have a UV 202 and a UV 201 which both show this. The phosphorus was used as a "getter" to improve the vacuum and keep it high, and I must say I never saw or heard of a soft 202. After the UV 201-A appeared, early in the twenties, only metallic getters

High school physics students used to use test tubes with rubber stoppers, or even milk bottles (glass), evacuate them with the school pump, and burn them for a few hours. Those sealed with sealing wax didn't last long . . .

were used. Perhaps the phosphorus was too hazardous.

The Moorhead illustrated has some very odd features. For instance, the grid is a close-wound helix, free-standing, with the top end unsupported. This might make the tube outstandingly microphonic, or perhaps the length keeps the resonant frequency too low to bother. I'll have to try it and see. The emitter is tungsten (Wolfram) and is a simple hairpin loop, deForest fashion. The collector is supported at each side, and in this tube is tilted.

The tilt puzzles me. The other two Moorhead types never have a crooked collector – they are ramrod straight. Mine, and all the others I have seen pictured, have this rakish tilt to them, like a JG's hat. Maybe Moorhead was careless with these, but I don't believe it.

Back in those "spark" days, detector sensitivity was *the* classic problem. After all the critical adjustments of voltages, what else could you do? You could mount a permanent bar magnet near the tube. If you found the right tilt, and the right spot, and the right polarity, and the right distance, you could up your sensitivity to a marked extent. For trial, of course, you took the magnet in hand, but to use it you had to provide a bracket. It is hard to remember so far back, but it seemed that the magnet was always aimed downward a little.

So it is possible – and I don't insist on this explanation – that the collector was tilted so that the magnet could be clamped level, which would eliminate the necessary tilt adjustment.

When broadcasting started, in 1921 or so, there were all kinds of tubes employed, including military types. Soon, however, there was a civilian market. The UV 200 and 201 gave way to the first super tube, the UV 201-A. This cost $9.00 when that was a day's pay. But it took only a quarter of the emitter power that the UV 201 did, but more and better, you could hear a marked difference in the signals.

In 1926, the ac tube was introduced. This activated the emitter surface with a separate heater, which could be heated by household ac with no trace of hum, thereby eliminating storage batteries with their damaging acid. The "no trace" was a purely theoretical concept – they did hum, slightly or a great deal, depending on circuit design.

Then the multi-base and high output devices proliferated, and the empty space age came into full flower.

Before WW II, the velocity-modulated valves appeared. One was the magnetron, used in radar and in cooking, and the other was the klystron. Both were essentially VHF devices.

Radar demonstrated that valve detectors were not so hot at UHF, and the old cat-whisker crystal detectors were studied. With zone-melting and doping of germanium and silicon, it was possible to build solid state devices on a production basis with uniform characteristics for the first time, and the solid state age had its beginnings. The first radar detectors used point contact devices, but even these had to be doped. By "forming" currents, a tiny fraction of the wire contact was diffused into the semiconductor, making a tiny local PN junction. The old-fashioned natural crystals already had their doping – of a random nature, which is why you had to hunt for "sensitive" spots.

The next development was the point-contact transistor, but this chapter is well-known. In England there was a vogue of making your own transistor from the wafer in a diode. The stubs of heater wires from a broken tube were used, with a stem as a mount, the whole thing formed, and presto! One had his own homemade transistor.

The experimenters used to make their own tubes, too. A number of workers used to burn out one filament of a double-filament headlight bulb, thus securing a plate or collector element. The filament was used in normal fashion as an emitter. This made a diode. A coating of tinfoil on the bulb made a base element with a *mu* of one tenth or one hundredth or some such. But considering the high impedance of the input, it was still possible to get some gain out of the device. High school physics students used to use test tubes with rubber stoppers, or even milk bottles (glass), evacuate them with the school pump, and burn them for a few hours. Those sealed with sealing wax didn't last long, but some workers went far beyond this. One ham actually made split-plate magnetrons of hard glass just before WW II. He said it was easy, but no one else duplicated his valves, so far as I know.

The original magnetron had one cylindrical plate. The next had a split plate, split into two troughs along their axis. This was in the early forties. The British invented the cavity magnetron, like an internal gear, with each cavity of such size as to be resonant at the operating frequency. Next, they were kept in phase by two wires that ran to alternate lips. This was a transmission line, and it kept the cavities oscillating in phase for more output power.

Magnetrons were capable of large outputs, but they were noisy. Small klystrons with tunable cavities were used as local oscillators for VHF superhets. Then came the tropo-scatter systems, with their 110 dB transmission paths – if you could call that

much loss a "path"! The land terminals used klystrons so big they didn't look like tubes at all; they were about seven or eight feet long, heavy, and filled with machinery for tuning. In tubes of that size, cathode emission is a problem, especially peak emission. You can't get it with just heat, direct or indirect. So an auxiliary cathode – filament – was set up and biased several hundred volts negative with respect to the main cathode. The auxiliary bombarded the main cathode and guaranteed enough peak emission. I know very little about it, really – a good look and ten minutes of talk was all I got. But I do know something else: This system was invented by A. McL. Nicolson, who also invented the indirectly-heated cathode. All commercial tubes are licensed under his patents. The bombardment-emission patent number is different, though: # 1,210,678. I don't know when it was filed – as early as 1915 or as late as 1919, or any time in between. The tropo system and the Texas towers date back to 1950 or so, some 30 years later.

During WW II Sylvania developed a tube which could be fired out of a cannon and survive . . .

There were various developments in these empty devices such as the lighthouse, or disc-seal tubes. They were so-called because of a kind of tiered construction that resembled a lighthouse. They were used at UHF and in radar systems. The highest development of the lighthouse tube is in the 416-B and -C triodes used in the TD-2 microwave system. They don't look much like lighthouse tubes, but that is what they are, essentially.

These old devices may be moribund, but they're taking a long time to die . . .

There are also the tiny nuvistor tubes of RCA, designed to compete with transistors. They can't, really, but they do have a high gain and good output for their size, and come in many types. They are all metal with a ceramic base which is also the mount. They are tiny enough to hide in your ear, should you want to.

For a long time, the tiniest tubes were the battery-operated hearing-aid types. They got smaller and smaller, and finally wound up as a flattened tetrode (glass) with wire leads instead of a base, tiny, and with a half volt filament. The idea was to burn three tubes in series from a dry cell. The filament drain was something like 20-30 mA.

During WW II Sylvania developed a tube which could be fired out of a cannon and survive. It came in two types – an oscillator tube, and a thyratron. Both were hearing-aid sized, but they used indirectly-heated cathodes. The oscillator was a Doppler radar oscillator/detector with a range of only a few yards. At its nearest approach to a target, just when it began to pull away from it, it would fire the thyratron (gas tube) which controlled a lot of current and could directly fire the fuse that exploded the bursting charge in the shell. This was one of the hottest developments in WW II and was known as the proximity fuse. The secret was a simple one – the tubes were mounted coaxially so that there were minimum stresses due to rotation of the shell, and the elements were so wispy-light that they didn't absorb much energy from the shock of firing. Other tubes were initially used in the prototypes, and the special proximity tubes were refinements of them.

The latest development is the traveling wave tube, used in the latest microwave systems. This one is a real darb. There is a spiral of tungsten (Wolfram) wire about the size and length of a screen-door spring. A signal starts at one end and is amplified in distributive fashion as it goes along, coming out the far end with considerable zap to it. I'm wrong: Make the inner diameter of the spiral more like a soda straw. An electron gun at the input end shoots a beam of electrons down the center of this spiral to a target at the far end. I don't know what the target voltage is – 1000 volts or more, I think. What keeps the beam from spreading? A strong magnetic field squeezes it into a narrow, tight beam. Now, signals in a wire transmission line travel slower than the same signals in free space, or near the velocity of light. So far as I know, the best you can do with an accelerated electron beam is about half that velocity. So the TW tube effectively slows the wave to considerably less than the electron beam velocity by making it follow a spiral, while the beam goes straight. And the fields of the traveling electrons, in sweeping the wave along faster than it would otherwise go, add power to it continuously from one end of the tube to the other. If the signal had to drag the electron beam along, it would *lose* power. Result: a very broad band, comparatively high-power amplifier that works in the higher GHz.

The tube itself is about 18 inches long, about an inch thick, with a swollen end where the gun is. No base, flexible leads. It looks like a fever thermometer for elephants.

I do not guarantee the accuracy of the sketchy explanation of the TW tube. I don't understand it myself, so that is the best I can come up with. But improving on it is not a project, it's a career.

The burden of my thesis is clear enough. These old devices may be moribund, but they're taking a long time to die. This vitality is due to their suitability for certain special jobs, and should keep them with us for those applications for many years to come. ■

The "Little Log" for 40 to 20m

by
Gordon Stewart VE4GS
26 Dominion Bay
Thompson, Manitoba
Canada R8N IL3

This log-periodic type of antenna will likely be of interest to SWLs who have a couple of dipoles or random wires tied to their receivers. Although designed for 7 to 15 MHz as an experiment in compact log-antenna performance, it is usable for receiving from 6 to 16 MHz.

Using it for transmitting on 7 and 14 MHz it showed about 2.5:1 swr. The swr throughout the range varies more than one would like for transmitting use, but seems to cause no problem when receiving. I would describe the general receiving performance as a very good dipole on all frequencies in the range or a slightly degraded 2 element beam. The front to back ratio seems to vary from unity to about 12 dB, depending on the angle of the signal off the back. Fading seems to be less than when a dipole is used.

The poles used to support the antenna should be at least 30 feet high – 60 feet would be even better.

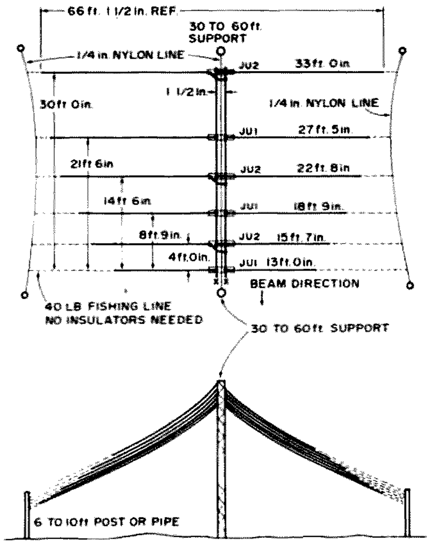

Figure 1.

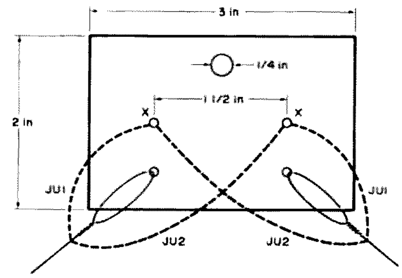

Figure 2: ¼" plexiglass (6 req'd., 1 at each center element).

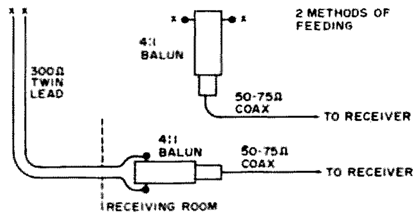

Figure 3: Two methods of feeding. Clean and solder all joints properly!

Be sure to transpose the element feeds as shown in Fig. 1.

The antenna can be fed through a 4:1 balun at the front element and coax run to the receiver. If a 300 Ohms line is available it could be run to the receiving room and then put into a 4:1 balun, with a length of coax used to the receiver. Because of the difficulty in making an all band antenna tuner, I suggest you use the balun, either ready made or from a kit which is available at a reasonable price.

This log, for casual use, represents the smallest size that is practical for the frequency range given – using performance versus size as the trade-off point. Wire size is not critical: #14 or #16 should be satisfactory.

Good listening! ■

Fading seems to be less than when a dipole is used . . .

Using A Bargain Surplus Keyboard

by
Cole Ellsworth W6OXP
10461 Dewey Dr.
Garden Grove CA 92640

I recently became the owner of an ASCII (American Standard Code for Information Interchange) encoded four-row keyboard purchased from a local parts emporium. Of relatively recent surplus vintage, it had originally been used in a computer terminal. The keyboard electronics consisted principally of a 40-pin LSI encoder chip similar to the General Instrument Corporation AY-5-2376. Several 7400 series chips composed the remainder of the circuit. Parallel format outputs included the 7-bit ASCII code, plus a parity bit, and the key-pressed signal (keyboard strobe). In addition, two key-switch non-encoded functions were available: "REPEAT" and "INT" (similar to WRU). All outputs were TTL-compatible positive true logic levels, although each of the eight data bit outputs was capable of driving only one TTL load.

The reason for acquiring the keyboard in the first place was to incorporate it in a computer terminal with video display to provide a man-microprocessor communications link. However, other applications came to mind, such as converting the 8-level ASCII code to Baudot 5-level code for amateur band use. And, should the FCC see fit to permit 8-level codes on the amateur frequencies, a proper interface would make such operation easy to accomplish. It became apparent that a number of keyboard support functions such as character counter, EOL indicator, repeat function generation, data output buffering, and keyboard strobe control would be required to provide maximum versatility in the aforementioned applications.

After an analysis of the keyboard support requirements and a projection of probable usage of the keyboard in varied applications, a logic diagram evolved that met all the requirements for my particular keyboard. It should be noted that keyboards, like canned soup, come in many varieties. Some designs have data outputs that are negative true TTL levels (mark = low level). Some have mixed outputs where the strobe is positive logic and the data bits are negative logic. Some recent designs have on-board LSI encoders that have a built-in repeat function (the strobe signal pulses at a ten Hz rate when a character key is held down more than about ½ second) while others do not even have a

repeat key. So as to make the support logic as versatile as possible, a number of options were provided in the final design and the result was named the Keyboard Interface – version 1 (KBI-1). Fig. 1 illustrates the interface unit logic diagram and connection to the keyboard. Fig. 2 shows the Digital Read Out (DRO-1) logic diagram which includes the EOL decoder.

Features

1. Provides buffered (up to 30 TTL loads) positive true data outputs (U3, U4) for the eight data bits with either positive true or negative true inputs.

2. Provides for strobed (3-state) outputs to allow connection to standard data bus, or normal 2-state outputs by means of jumper JM5.

3. Provides repeat function generator if desired (JM6).

4. Allows strobe and repeat functions from either positive or negative logic keyboard outputs (JM1, JM2, JM3, JM4).

5. Provides four variations in strobe pulse outputs:

a. Negative-going strobe pulse remaining at a low level until key is released (strap JM7 A to B).

b. Positive-going strobe pulse remaining at a high level until key is released (strap JM7 A to C).

c. Negative-going strobe pulse with variable delay and variable pulse width (strap JM7 A to D).

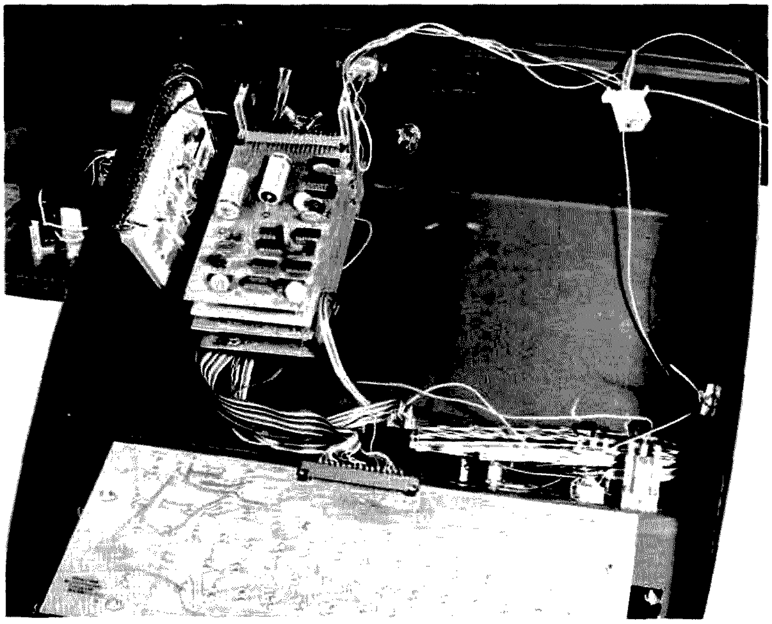
d. Same as letter c except positive-going strobe pulse (JM7 A to E).

6. Provides a character counter and LED display that counts only the printing ASCII characters plus space bar. Counter is reset to ØØ on receipt of ASCII LINE FEED function.

7. Provides End-Of-Line (EOL) indication at any desired character count. EOL indicator is also reset by the LINE FEED function.

Circuit Notes

For interface to keyboards with positive true logic outputs, U3 and U4 should be the 74367 non-inverting 3-state buffers. In this



Inside view of console showing method of mounting and interconnecting the five PCBs and keyboard. The PCB on the far left is a catch-all for peripheral drivers and other accessory functions.

case U3A and U4A are jumpered as follows: U3A – JM1 open, JM4 A to B; U4A – JM2 open, JM3 A to B. Note that in this configuration all keyboard data outputs must be positive logic including the strobe and repeat signals. There is no provision for handling negative logic strobe and repeat signals when data bits are positive logic. If required, outboard inverters could be used in this case.

For interface to keyboards with negative logic data outputs and *negative or positive* logic strobe and repeat signals, U3 and U4 are 74368 inverting buffers. Pinout and control levels are identical with the 74367. For a negative logic strobe from the keyboard, U4A JM2 is open and JM3 A to B. For positive logic strobe, JM2 is jumpered and JM3 A to C. Similar jumper conditions apply to U3A for negative or positive logic REPEAT signals.

If the keyboard has on-board repeat character function, then U1, U2A, and U3A are not required and may be disabled by connecting JM6 A to C (in this case U1 and associated capacitors and resistors need not be installed). If keyboard has the repeat function key but no repeat oscillator, connect JM6 A to B for a ten Hz pulsing of the keyboard strobe.

If normal non-strobed bipolar data outputs are desired (no high impedance third state), connect JM5 A to C. If 3-state data outputs are desired (U3 and U4 pass data only during presence of keyboard strobe pulse and outputs revert to a high impedance state when strobe pulse is not present), connect JM5 A to B. For initial tests of the KBI-1, JM5 should be strapped A to C.

The four variations in strobe signal output are selectable by JM7. Connect JM7 A to B for negative-going strobe staying low until key is released, JM7 A to C for inverse (positive-going strobe staying high until key is released). JM7 A to D and A to E select negative or positive strobe pulses as required. U14A R5 and C4 are selected to provide the

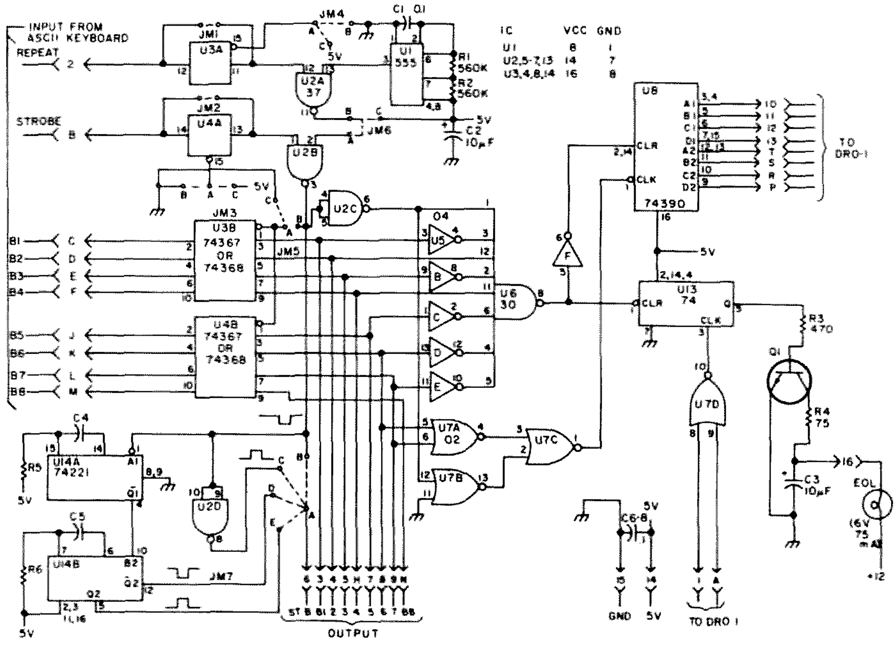

Fig. 1. Interface unit logic diagram and connection to keyboard.

required strobe delay, and U14B R6 and C5 are selected to provide the desired pulse width.

Thus, it is apparent that while the KBI-1 will provide interface for the majority of keyboard logic configurations, all possible permutations are not available. The KBI-1 is *not* directly compatible with non-coded keyboards, keyboards coded for IBM codes such as EBCDIC or SELECTRIC, or Keypunch (Hollerith) codes. In other words, before you consider use of the KBI-1, your keyboard must meet three conditions: 1. Outputs must be in a 7-bit parallel ASCII encoded format with or without parity bit. 2. Outputs must be TTL-compatible. 3. Must have a strobe (keypressed) signal output. The character counter section of the KBI-1 provides a two-digit display (ØØ to 99) of the number of printing characters (and space bar) generated. A portion of this circuit is located on the DRO-1 board (see Fig. 2). It will not count control functions. The display is reset to ØØ whenever LINE FEED key is pressed. EOL indication is provided by lamp DS-1. This circuit operates by detecting a preset number determined by strapping outputs of U11 and U12 to the inputs of U7D. Decimal thumbwheel switches (S1, S2) may be used for convenience in changing the set point if desired. Otherwise, straps are run from U7D inputs to the desired outputs on U11 and U12. At the preset count, the EOL indicator illuminates and remains illuminated until LINE FEED key is depressed.

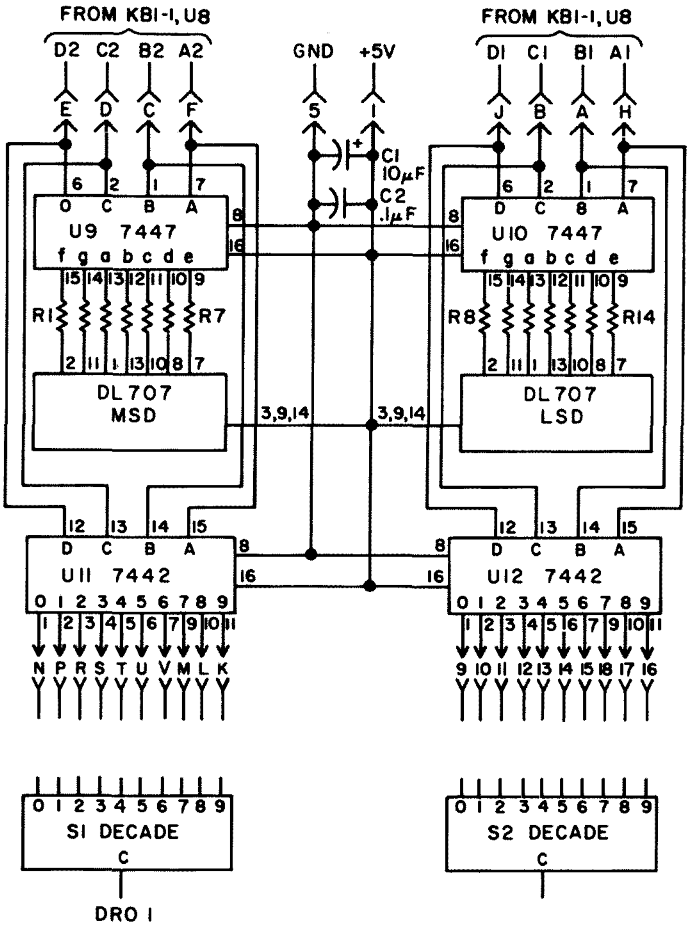

Fig. 2. Digital Read Out logic diagram, including EOL decoder.

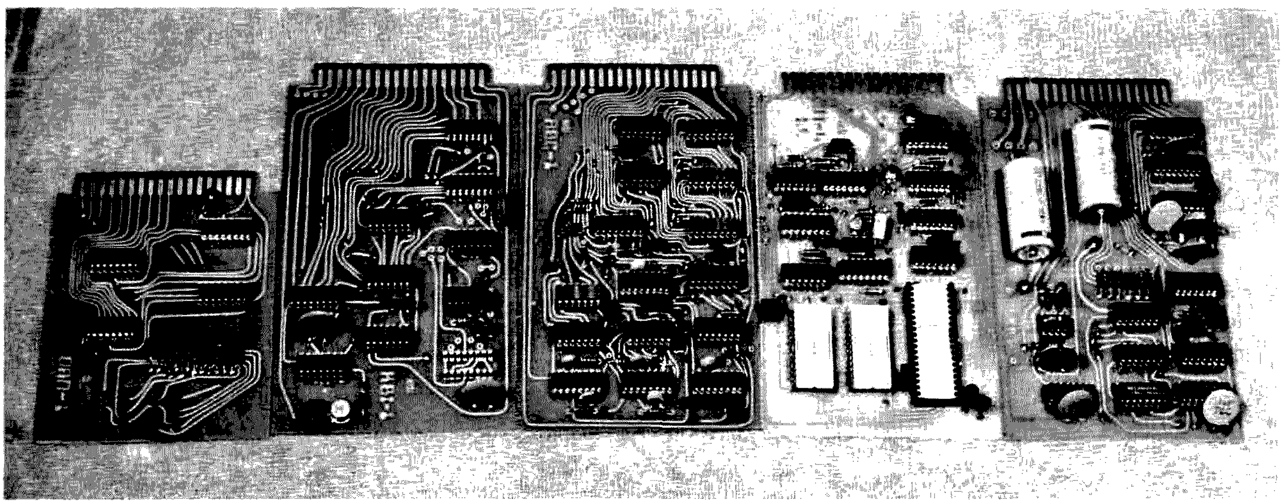
Construction

Circuit layout and wiring is not critical provided normal rules of TTL logic are followed. Printed circuit boards greatly facilitate and speed construction and are recommended in particular to those who are not familiar with digital logic hardware. New, high quality components should be used to reduce or eliminate debugging problems. Surplus or reclaimed components may be used if you have the proper facilities



The five printed circuit boards from left to right: DRO-1 character counter and display driver (short board), KBI-1 interface, ABC-1 ASCII to Baudot converter, UT-4 i-f main board, UT-4 i-f auxiliary board.

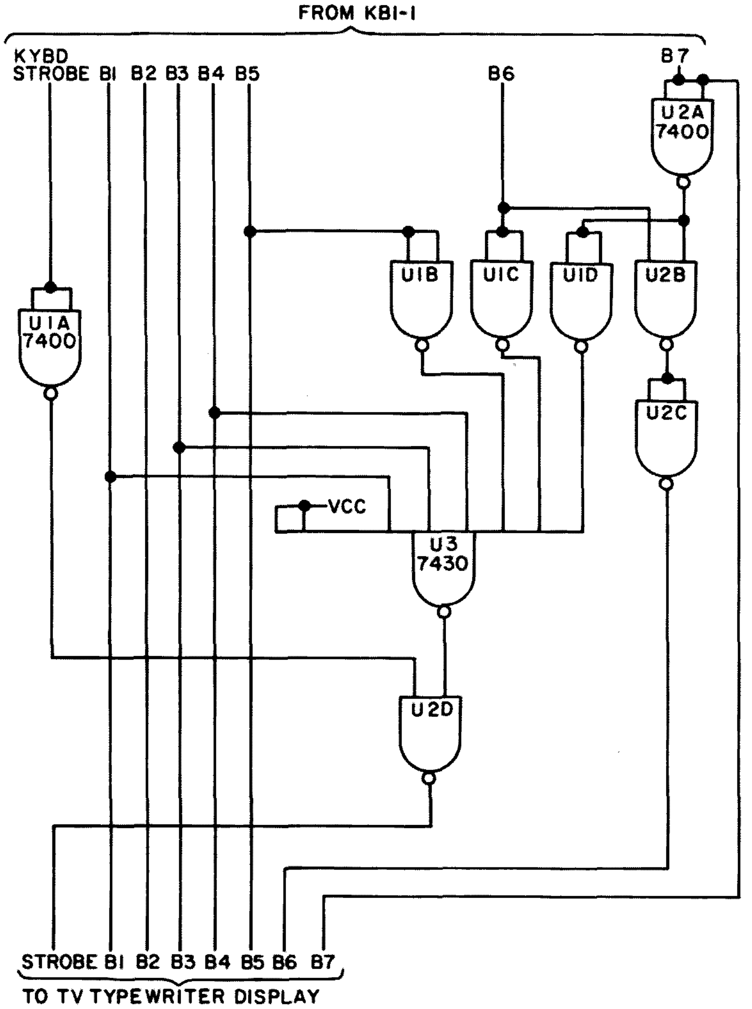


Fig. 3. Adaptor for driving SWTP TV Typewriter video display from KBI-1.

for testing. Sockets or Molex pins are recommended for the ICs as even brand new chips from a franchised distributor have been found defective. Check and double check the orientation of pin 1 of the chip with the socket.

CI, the timing capacitor for U1, may require selection to keep the repeat function rate at ten Hertz or less. R1 and R2 should be 5% ¼ Watt. R4 is required for the recommended EOL lamp and +12 volt supply. R4 may be replaced by a jumper if a 5 volt lamp and +5 volts are used in this application.

Printed Circuit Boards

Electronic Development Inc. (EDI)[1] of Salem, Oregon has been authorized to make the two printed circuit boards (KBI-1 and DRO-1) available for this project. No other sources of PCBs are expected to be available. PC boards only, or complete kits may be obtained. See EDI ads in *73* for description and availability. The boards are high quality epoxy glass, double-sided with plated-through holes and fit standard .156 inch spacing, 18-position double readout edge connectors. The edge connector references on the logic diagrams are identical with the EDI PCB edge connections.

Troubleshooting

At the time of this writing, three persons have built the KBI-1 and three different ASCII encoded keyboards have been used. These were surplus units manufactured by Clare-Pendar, Microswitch and Tektronix. Various problems were encountered in check-out including poor solder joints, missed solder points, trace to trace solder bridges, overloaded power supplies, and in several instances defective ICs were found. In each case a carefully thought out, logical approach to troubleshooting pinpointed the problem area. While a good triggered oscilloscope is a most useful adjunct to logic circuit troubleshooting, it should be pointed out that Peter K6SRG debugged and checked out early prototypes of the KBI-1, the ABC-1 ASCII to Baudot Converter, and UT-4 i-f circuits using nothing but a VOM (and an ice cube to find a temperature sensitive 74390!).

The KBI-1 was designed to be located in the immediate vicinity of the ASCII keyboard. Leads from the keyboard data outputs to the KBI-1 should not exceed 20 inches. Lines of greater length will cause ringing, especially on the keyboard strobe pulse. Ringing on the strobe pulse will cause multiple outputs from a single keystroke. Jim WA7ARI used a six foot cable between his keyboard and the KBI-1 but it was necessary to use type 75188 line drivers at the keyboard and 75189 line receivers at the KBI-1 inputs to prevent ringing. The same line length restrictions apply to the KBI-1 outputs. You must use transmission line techniques for any line over approximately 20 inches.

KBI-1 with TV Typewriter Display

Many RTTY enthusiasts have built the Southwest Technical Products Corp. (SWTP) "TV Typewriter" video display. Fig. 3 illustrates a special adaptor used between the KBI-1 output and the TV Typewriter input so that the video display has a CR/LF on receipt of LF instead of CR. The video display will still provide automatic CR/LF at the end of its 32 character line if an LF is not received prior to this point. Credit is due WA7ARI for developing this circuit.

Acknowledgements

Recognition and appreciation of their contributions, comments and

encouragement are due members of the 3612.500 autostart net, in particular W6FFC, W6GQC, K6SRG, WB6WPX and WA7ARI. Thanks is also due those members of the net whose patience was sorely tried during the development period. Others who contributed comments and suggestions included K2SMN, WA5NYY and KL7HOH. The author extends his apologies to anyone whose contributions were overlooked.

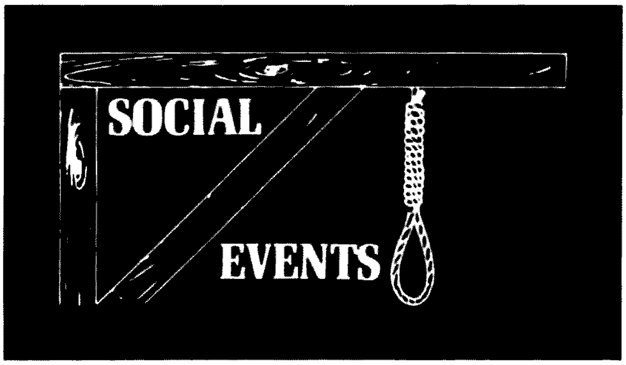
ASCII to Baudot Conversion

A forthcoming article will describe an ASCII to Baudot converter (ABC-1) that converts ASCII data from the KBI-1 to parallel format Baudot 5-level code and outputs this data to a FIFO/UART combination such as the UT-4[2]. ■



SOUTHFIELD MI
JAN 18

Southfield Amateur Radio Club's 10th Annual Swap and Shop, the largest in Michigan, will be held January 18, 1976 at Southfield High School, Ten Mile and Lahser Rds., Southfield, Michigan. Tickets $1.50. For more information regarding tickets and/or tables write to Mr. Robert Younkers, 24675 Lahser Rd., Southfield, Michigan 48075.

WAUKESHA WI
JAN 24

The 4th annual Midwinter Swapfest of the West Allis Radio Amateur Club will be Saturday, January 24, 1976 starting at 8 am at the Waukesha County Expo Center. This year in new larger building! Directions: I-94 to Waukesha Co. F, south to FT, west to Expo Center. Talk-in on 146.52 MHz. Tickets $1.50 advanced, $2.00 at door. (Dealers: advanced registration only.) Write: WARAC, P.O. Box 1072, Milwaukee WI 53201.

VERO BEACH FL
MAR 20-21

The Bi-Centennial Treasure Coast Hamfest will be held at the Vero Beach Community Center Saturday and Sunday, March 20 and 21, 1976. Sponsored by Vero Beach Amateur Radio Club, Inc., and St. Lucie Repeater Association, P.O. Box 3088, Vero Beach FL 32960.

WASHINGTON DC
MAR 24

1976 ARRL Technical Symposium on Mobile Communications will be held on the evening of Wednesday, March 24, 1976 at the Statler Hilton Hotel, Washington, DC. Areas of interest are: HF/VHF/UHF mobile communications, repeater technology and operations, signaling and control techniques, special mobile communications (AMSAT, ATV, RTTY, etc.); especially subjects of interest to both amateur and commercial mobile radio users. Summaries are due by February 1, 1976. Manuscripts, photo of author and biographical sketch of amateur/electronic background due by March 1, 1976. Write: Paul Rinaldo K4YKB, 1524 Springvale Ave., McLean VA 22101 or call (703) 356-8918 evenings.

ST. CLAIR SHORES MI
APR 4

The South Eastern Michigan Amateur Radio Association is holding its Eighteenth Annual SEMARA Swap 'N' Shop on April 4, 1976, from 8 am EST to 3 pm EST. It will be held at the South Lake High School in St. Clair Shores, Michigan, on the Southwest corner of Nine Mile Road and Mack Avenue.

HAM HELP

According to long-standing policy, *73 Magazine* makes a continual effort to match those in need of technical help or instruction with those who feel they can offer it. If you find yourself in one of these two categories, please do yourself and amateur radio a favor by contacting Ham Help, *73*, Peterborough NH 03458.

W5YF, the SMU ARS, is now offering Novice licensing mini-courses.
TIME: 9:30 am – 12 noon
DATES: Every 2nd, 3rd and 4th Saturday of the month.
WHERE: W5YF, Rm. 324, (Aruth Eng.) Southern Methodist Univ., Dallas TX 75275 (attn: WA2JRX).

I'd be glad to offer some HAM HELP.

Fred Layton
Rt. 18 Box 430
Olympia WA 98502

Our "Amateur Radio Education Association" started meeting in January, 1975, and now has about twenty active members.

While most of our members are already licensed, we would be very much interested in having non-licensed people, with an interest in amateur radio, get in touch with us. The club has the potential to set up classes for these people and our instructor, William Farone (Extra Class), has the ability to set up a comprehensive instructional program in addition to being able to provide the motivation for learning.

Our base of operation is in Bergen County, which is in the northeastern part of New Jersey. For practical purposes, I think anyone living within a ten mile radius of the George Washington Bridge would be able to participate in our activities.

We would sincerely appreciate any help you could give us in recruiting new members — perhaps a mention of our organization in the "Ham Help" column would reach a number of both "would-be" and currently licensed amateurs.

Improve Your SSTV with The FRAMER

by
E. Sommerfield W2FJT
49 Spring Road
Poughkeepsie NY 12601

Next to multi-path sync problems, there is nothing more aggravating than the reception of only a portion of an SSTV picture (frame) completely out of vertical synchronization, and subsequently overlaid by a different portion of the same picture when the next frame starts.

This article describes a simple remedy that forces a vertical sync pulse at the beginning of each transmission, i.e., when the transmit/receive relay is activated. This will insure that when your transmission starts, your camera begins scanning from the beginning of a frame.

The Robot Research Inc. Model 80A SSTV camera was used as the example in this article, but the principle can be applied to other cameras that use the line frequency, together with a frequency divider, to obtain the vertical scan rate.

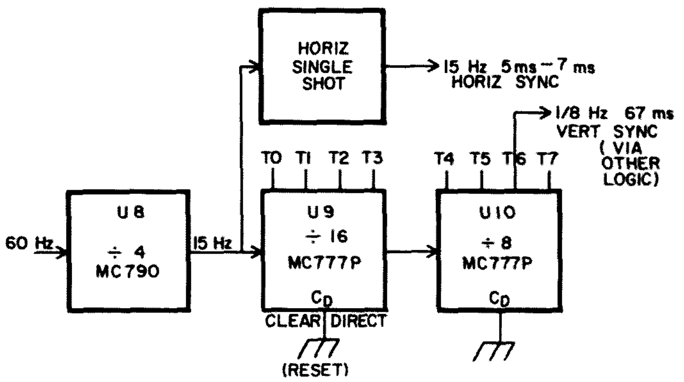

Fig. 1.

Fig. 1 shows a block diagram of the vertical timing chain of the Robot 80A SSTV camera; this is a common configuration for obtaining an 8 second vertical frame interval. Notice that the vertical sync pulse, which is used to reset the receiving monitor vertical sweep deflection, is free-running. If, for example, your transmission begins when T6 is "on" and T0-T5 are "off," then your picture would be transmitted starting at the center and continuing for one half a frame before a vertical sync pulse is transmitted. Likewise, at the monitor, one half a frame would be displayed starting wherever the monitor vertical deflection was at the time transmission began.

The simple solution to this problem, shown in Fig. 2, is to reset the vertical timing chain whenever a transmission begins, and hold it in the reset condition for the length of a vertical sync pulse: about 30 to 70 milliseconds. (Pulse times longer than 70 milliseconds will not adversely affect operation of either the camera or monitor.) When the 80A vertical timing chain is in the reset state, a vertical sync pulse is generated by the camera.

Fig. 3 shows a typical frequency divider. Most frequency dividers, also known as counters, have provision for at least one DIRECT input called a CLEAR DIRECT (Cd). A direct input is an input that overrides any clocking, toggle, or counting operations. Due to the grouping of the divider elements of 4 to a DIP module, each Cd input usually resets 4 divider elements. The

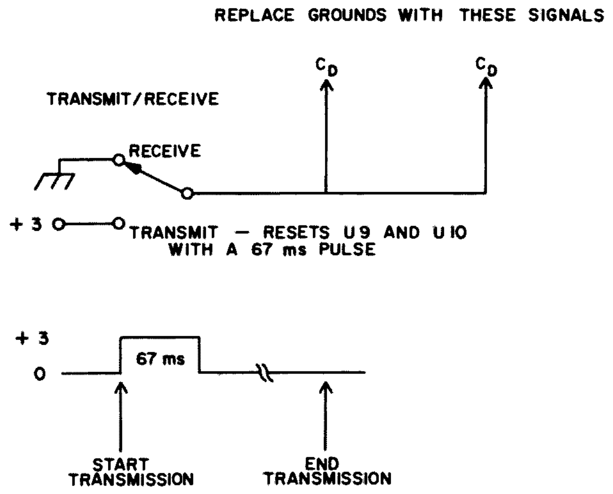

Fig. 2.

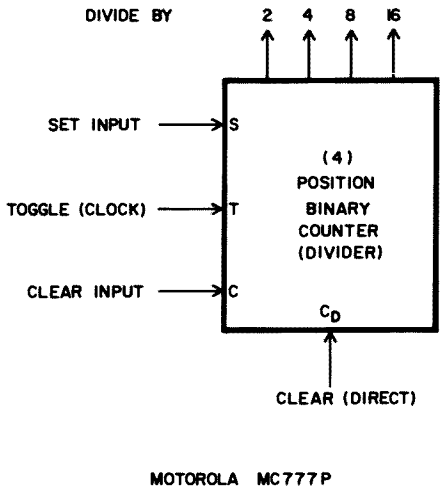

Fig. 3.

80A has 2 such divider modules, U9 and U10.

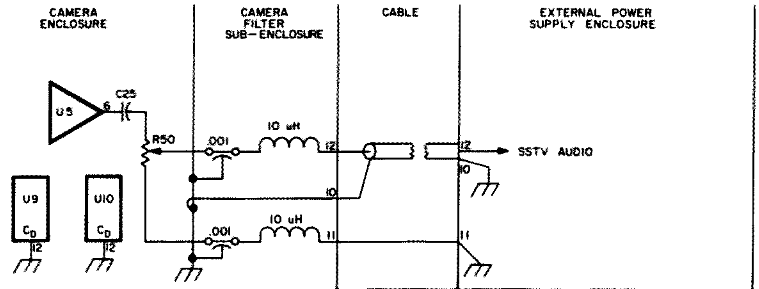
There are many electronic ways to generate a single vertical sync pulse in coincidence with the transmit/receive relay closure, but the relay circuit shown in Fig. 4 is the simplest and easiest to implement. An electronic version using the unused half of U4 was breadboarded and tested in the camera, but was not implemented due to the extensive modifications required to the U4 land pattern. It is shown in Fig. 5(a) for the reader who is inclined towards electronic-only circuits.

The relay circuit, shown in Fig. 4, operates as follows:

In receive mode, the relay K1 return path via the transmit/receive (T/R) relay is open, and C1 will charge to +15 volts through R1 in about one second. When the T/R relay is closed at the beginning of a transmission, C1 will discharge through the parallel combination of R1 and the resistance of the coil of relay K1. The value of C1 was chosen in conjunction with the 1000 Ohm relay coil resistance, so that that the current through relay K1 coil would not drop below 3 mA until about 70 ms after the T/R relay closed.

Who wants to hear, "Send me a few more frames, the first two were out of sync"?

Fig. 4(a). Original wiring.



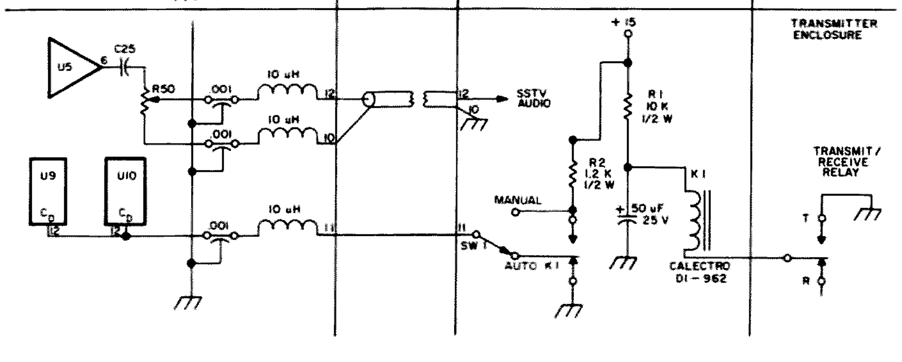


Fig. 4(b). Modified wiring.

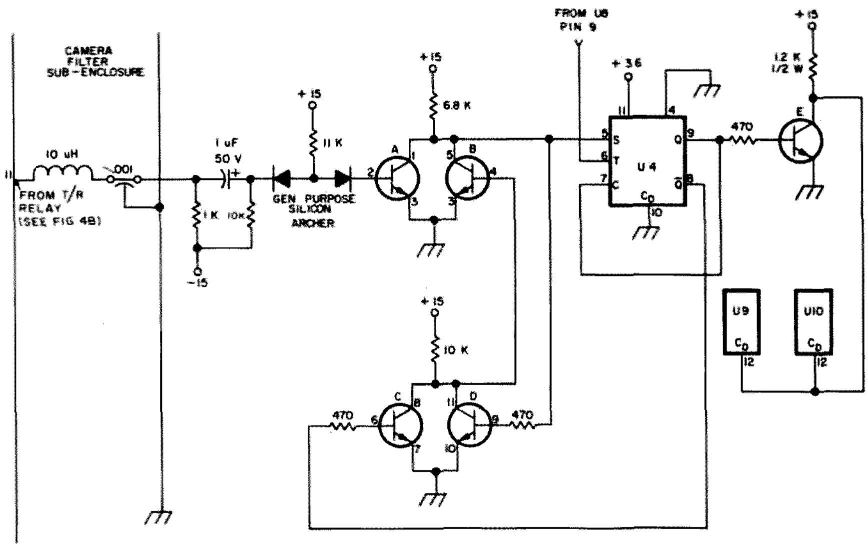

Fig. 5(a). All resistors ½ Watt. Transistors A, B, C, D and E are RCA CA-3046 five transistor array module.

Relay K1 will open when the current in its coil drops below 3 mA. C1 will discharge to +1.6 volts and stay at this value until the T/R relay opens. The current through K1, at +1.6 volts, is 1.6 mA, which is not sufficient to keep K1 closed. Relay K1, therefore, will close at the beginning of a transmission and reopen after about 70 ms.

When relay K1 closes, +15 volts is applied, via R2, to the Cd inputs of both U9 and U10, the vertical divider chain. When this occurs, all 8 counting elements of the divider chain are reset, and, as was mentioned earlier, the 80A generates a vertical sync pulse. The value of R2 was chosen so that the voltage on the Cd signal line is about +1 volt as required by the manufacturer's specification for the MC790P. The rearrangement of cable wires between Figs. 4(a) and 4(b) was necessary in order to obtain the wire for the reset line. The video output circuit is functionally the same in both circuits.

Those readers who are familiar with relay operation might question the lack of concern with relay contact bounce. Relay contact bounce is present of course, but the vertical sync filter in the monitor only passes sync pulses longer than about 30 ms. Contact bounce only lasts for about 10 ms to 20 ms, so no problem was experienced in this area.

Switch SW1, which is optional, allows manual reset of the counting chain. If SW1 is left in the manual position, 1200 Hz will be continuously generated. This 1200 Hz-only condition is useful for calibrating the 1200 Hz frequency.

The electronic circuit shown in Fig. 5(a) has been described in many publications, including the RTL Cookbook[1]. Its operation is summarized by the waveforms shown in Fig. 5(b).

Fig. 6 shows how to modify the printed circuit pattern in order to isolate the Cd input pins: pin 12 on U9 and pin 12 on U10.

Fig. 4(b) shows how pins 10, 11 and 12 on the 80A power plug sub-panel are modified to permit pin 11 to be used for the Cd reset signal line. The power plug connections at the power supply must also be modified as shown in Fig. 4(b).

Relay K1 should be located in the external power supply enclosure in order to avoid

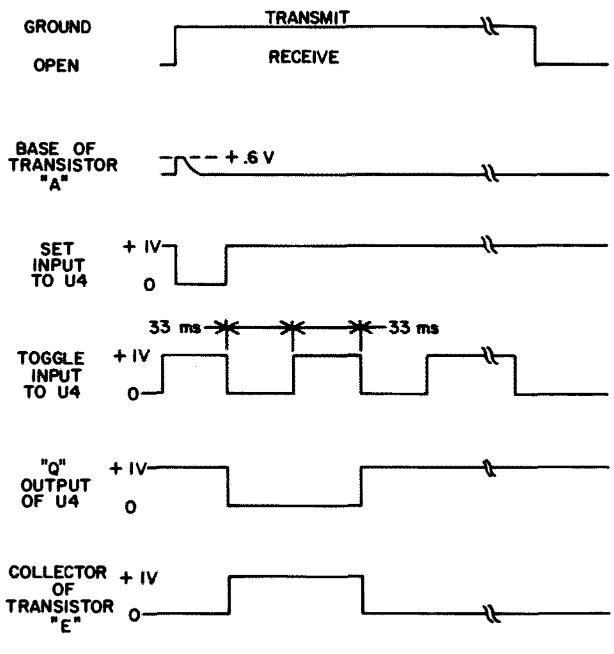

Fig. 5(b).

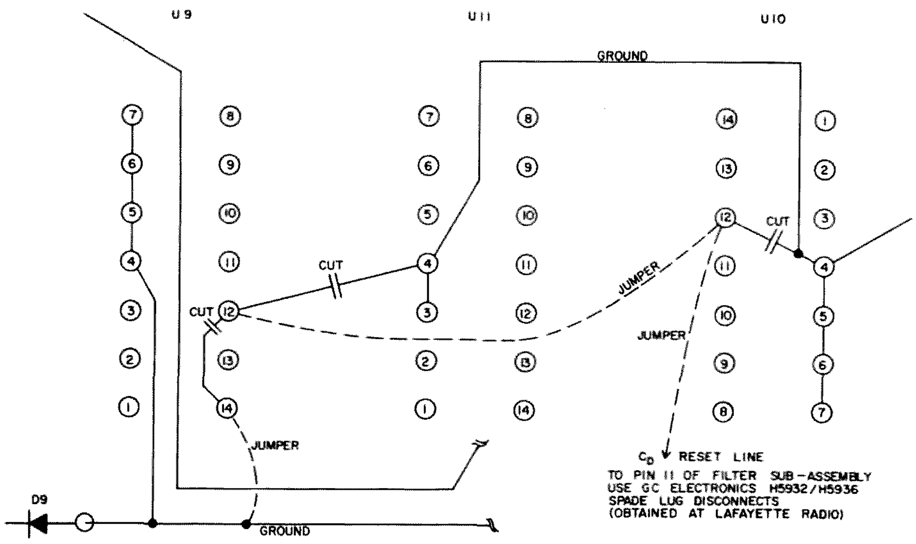

And all this for about $6.00 . . .

Fig. 6. Robot 80A SSTV Camera, wiring side of board.

transient current noise pulses on pin 5, the power supply ground wire to the 80A.

The addition of this FRAMER (FRAME Resetter) to the 80A lets you transmit more complete frames than was possible before; after all, who wants to hear "send me a few more frames, the first two were out of sync"?

The inclusion of the optional manual switch feature also eases the 1200 Hz calibration by permitting a continuous 1200 Hz signal generation.

All this for about $6.00. ■

The Experimenter's Dream Card

by
Robert J. Buckman K9AIY
PO Box 1471
Green Bay WI 54305

In amateur projects involving integrated circuits, some sort of circuit card is a must . . .

Most amateurs have had some experience with printed circuits or their predecessors, perfboard. This article summarizes my experience with printed circuitry and develops a general purpose card for amateur use.

The advantages of printed circuit cards for breadboarding or permanent construction are many! Serviceability, dense packaging, reproducibility and reduced wire lengths for improved high frequency response are examples. In amateur projects involving integrated circuits, some sort of circuit card is a must.

Industry has used printed circuits for years and has adopted several standards in sizes and board edge pin placement. Card cages are available which will accept these standard size cards and allow very dense packaging. Standard individual cards with identical circuits on them allow swapping out cards during troubleshooting until the faulty card is located.

Many companies sell standard and special purpose cards either blank or with a pattern etched on them. If you have priced the cards available through Vector, Cambion, Circuit-Stik, EECO or the others, you can see why this article was written.

Card edge connectors are another expensive item; generally, the more pins you try to cram into a socket, and the closer together they must be, the more the connector will cost. We amateurs with limited budgets must find the cheapest connector that will do the job without pricing the project out of sight.

Lately, the simpler and smaller-sized card edge connectors have been turning up at hamfests and surplus markets at substantial savings. This fact is the primary motivation for the circuit cards developed here.

Industry standard card sizes start around 3" in width; several manufacturers produce cards with 4½", 6", and 8½" width. Lengths are not so standard, with 4½" a minimum and 17½" a maximum. Before deciding on a size, let's review the types of circuit card fabrication and applicability to amateur projects.

There are three basic methods of applying a circuit pattern to a card blank: direct etch where the desired copper paths are covered with tape or paint resist before etching, photographic sensitization of a treated board (photoetch) prior to etching, and additive processes where the pattern is added to a blank board (Circuit-Stik is the best example although some companies are plating the desired patterns onto a board). Direct etch is limited by the dexterity of the applier and to simple circuits that are not densely packed. Circuit-Stik is fast but expensive. Photoetch is the choice remaining and, once you get started, relatively inexpensive. This article uses the photoetch technique.

The card stock available will also determine the techniques that are feasible for the amateur. The first card stock to be available at reasonably low prices was the epoxy paper circuit board which came with

one or both sides coated with copper and usually undrilled. Epoxy glass boards are now available, are reasonably priced (about a penny a square inch or less), and are less susceptible to moisture damage. Pre-drilled or punched card stock is available with holes on a standard grid, either 0.20 inch or 0.10 inch. The 0.10 inch perfboard is ideal for integrated circuit cards and only slightly more expensive. Cards are also available with photosensitive coatings for slightly more. I prefer to coat my own boards but that takes practice since it is possible to produce a too thick or too thin coating.

In designing a general purpose card, you must consider both its uses and the rough-order-of-magnitude quantity of boards to be produced. I presently have over twenty projects in some phase of design or construction. Many of these projects will use several circuit boards. A review of these projects shows many to be entirely digital, or at least, use the dual-in-line (DIP) package.

My circuit card is based then on the standard DIP outline. With all the different configurations and pin counts (8, 14, 16, 18 and 24), etching power buses on the card has several disadvantages. If many DIP chips must be accommodated, say thirty or so, the number of holes to be drilled will be over 300 without considering interconnections or discrete components! Test points, trimpots, switches, lamps and LEDs must be considered and allowed for. Finally, sockets and input/output connections may be needed.

A review and design tradeoff of all the above considerations have resulted in the general purpose card described here. The basic card is epoxy paper perfboard with 0.10 inch grid holes, copperclad on one side,

If you have priced the commercially available cards, you can see why this article was written . . .

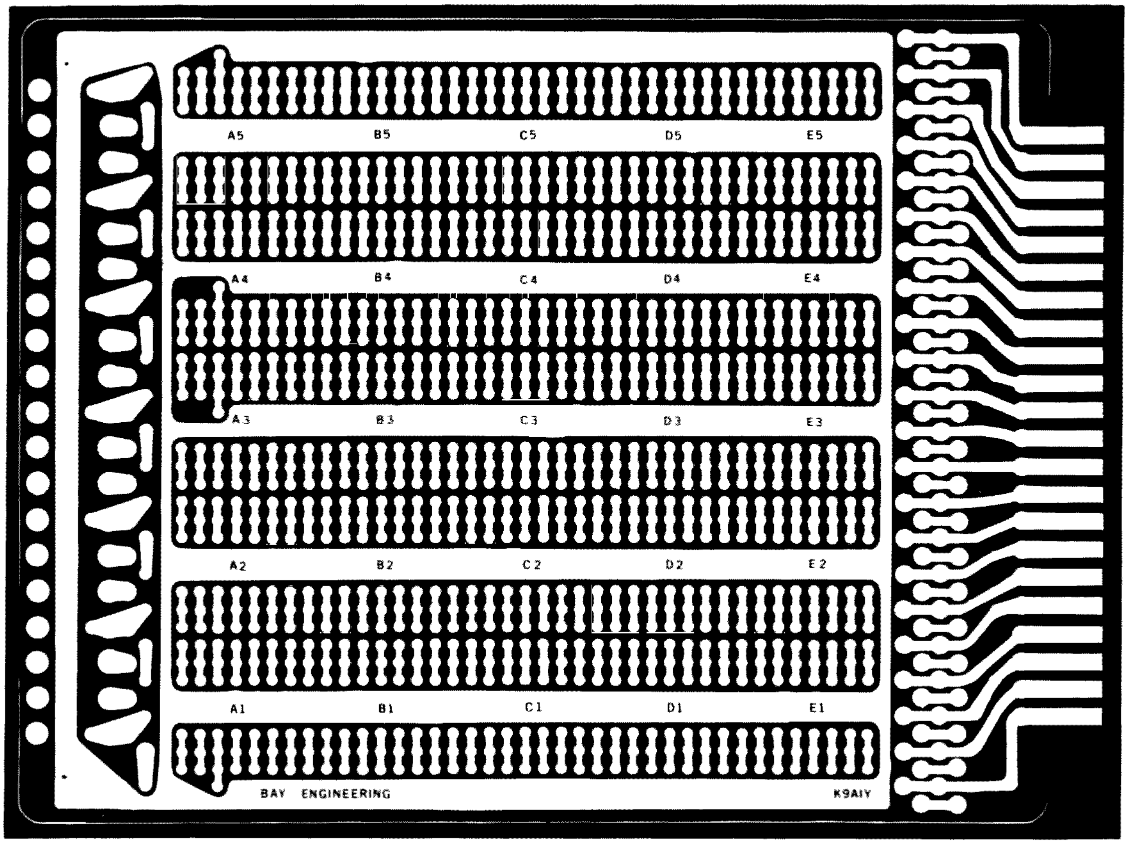

Fig. 1. Full size copper-side foil pattern.

4½" wide and 6" long. Vector makes the boards I have used (part number 64P44-062EPC1), but other manufacturers make similar boards. Fig. 1 is the full size copper-side foil pattern and Fig. 2 is a component-side overlay showing one of the many configurations possible.

This board will hold 25 14-pin DIP chips, six test points and 7 trimpots simultaneously. A maximum of 30 14-pin chips and 19 test points may be mounted. 24-pin DIP chips also fit on this board to a maximum of 9 24-pin packages. 22 input/output pins, spaced 5/32 (0.156) inch apart form the board edge connector. If a double-sided board edge connector is desired, a Circuit-Stik connector pattern sub-element (part number 1365-005) can be overlaid on the component side and will mate with pads already provided on the foil side. The dual-sided connector will provide 44 independent input/output connections; however, the older 22 pin board edge connectors are more readily available than their dual-sided brothers.

The two additional pads connected to each DIP pin allow a daisy-chain connection to each pin (one wire in, one wire out). Since only a ground bus is etched on the foil side, the types of ICs are not restricted to those with power connections on any particular pins. None of the commercially manufactured cards I have seen allow mixtures of 14, 16 and 24 pin DIP chips or allow test points and trimpots simultaneously.

A variation of this board, the same physical size but without foil or allowances for trimpots or test points, has been used with wirewrap sockets which are finally becoming available. A plastic hand wirewrap tool has become available from Cambion (part number 435-1816-01-00-16) for the nominal price of two bucks. Up to 45 14-pin wirewrap sockets may be stuffed on a board this size. Unless the complete project will fit on this board, the 44 maximum input/output connections will restrict the number of ICs that can be used. The cards above can be constructed for under five dollars in quantity and are about half the price of a similar commercially manufactured card. ■

COMPONENT SIDE

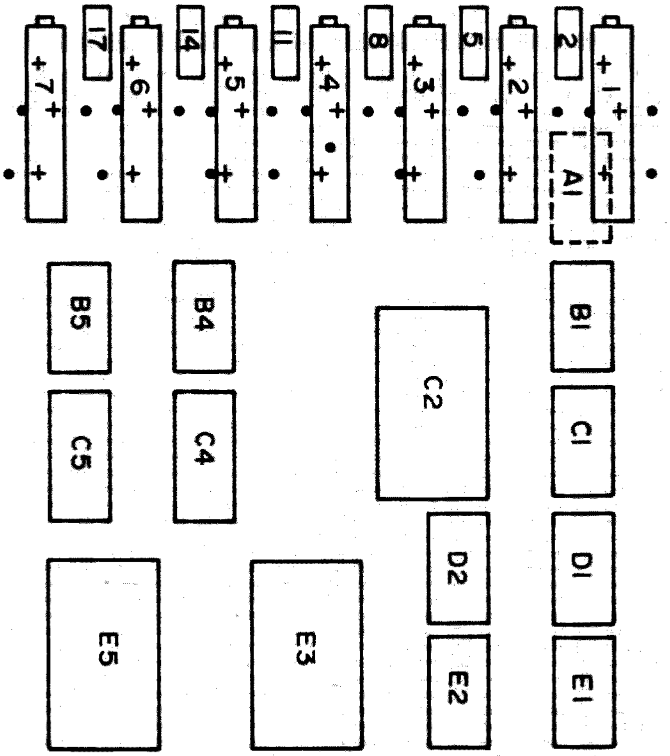

Fig. 2. Component-side view of one example configuration.

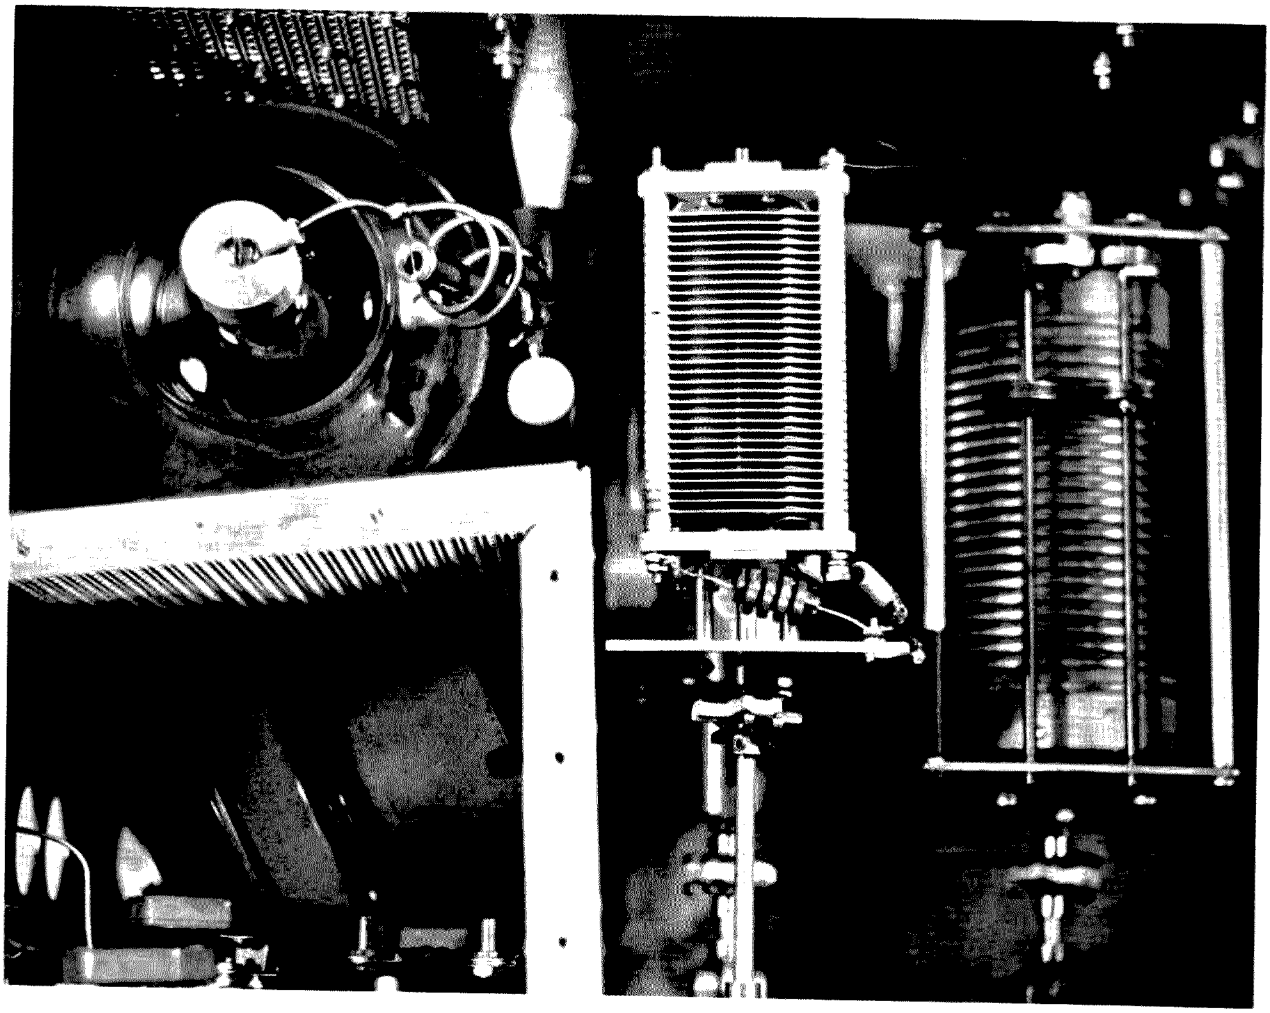
Run The Legal Limit with One Shoe

by
Jack B. Friend WA7IEO
315 Carole Circle
Salt Lake City UT 84115



Amplifier plate circuit.

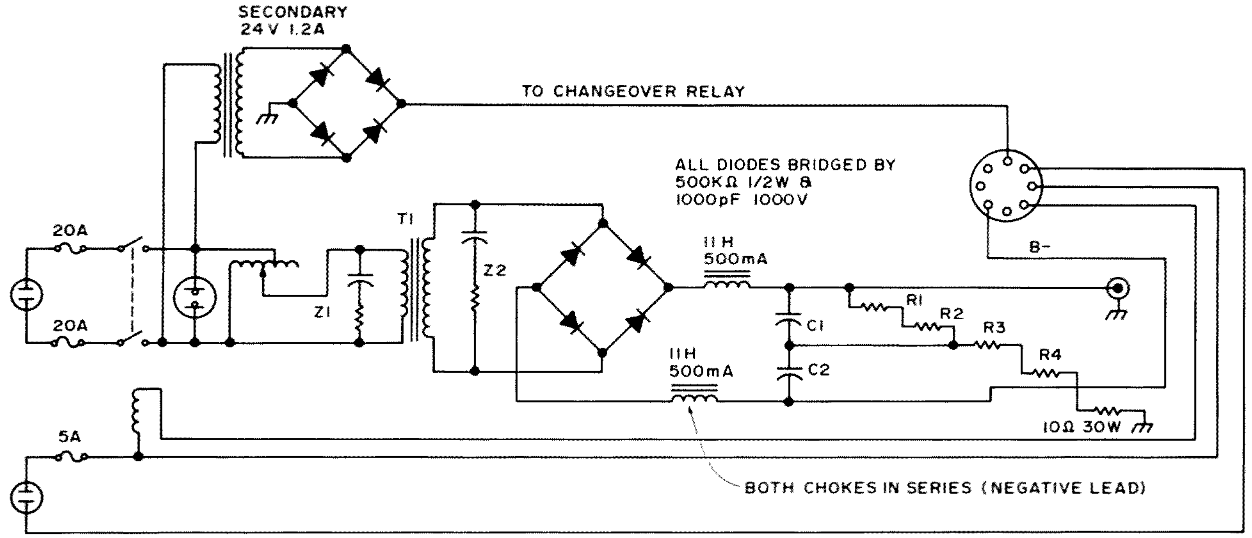


Fig. 1. High voltage power supply. Note that the high voltage bridge actually has 40 diodes.

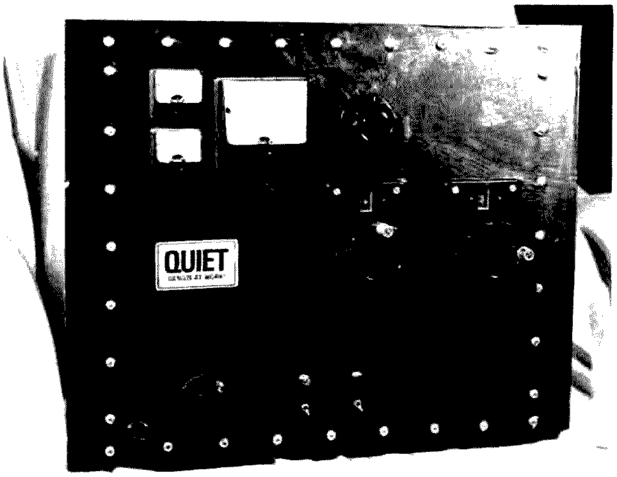
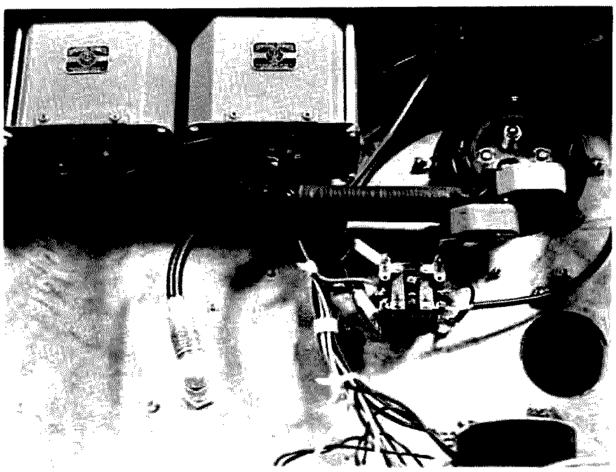
The design of this grounded-grid linear allows the use of either the 3-1000Z or 4-1000A. The components were chosen to operate well within their limits, my monetary possibilities, and to offer the best voltage regulation in the power supply. Large overall size, weight and no portability resulted, but then those weren't factors here.

Filament Circuit

Two 7.5 volt, 10 Amp transformers that just fit under the four inch chassis were found in unused surplus for a good price and work well. Each side of the filament is fed through a bifilar wound choke. Each choke is wound with #10 wire on the whole length of an Amidon ferrite rod – the kind available in the Amidon kit. This heavy construction results in very little loss of voltage through the chokes. The face of the filament voltmeter is marked to give precise setting of the voltage. The variac in the line offers one the ability to slowly bring the filament up to temperature. This procedure is highly recommended by Erwis Isgitt W7SLC of Eimac in Salt Lake City, to improve tube life. Be sure to fuse the variac, in this case at 1.6 Amps. The B-return is to only one of the two transformers to avoid difficulties with balancing.

In this linear there is no tuned input, but if matching presents a problem or there are not at least 125 Watts available for drive, put one in. Note the chart for a tuned input to a 4-1000A at plate potential of 5 kV.





Front panel of amplifier – note turns counter knobs; underside of chassis showing filament transformers, tube socket, and relay.

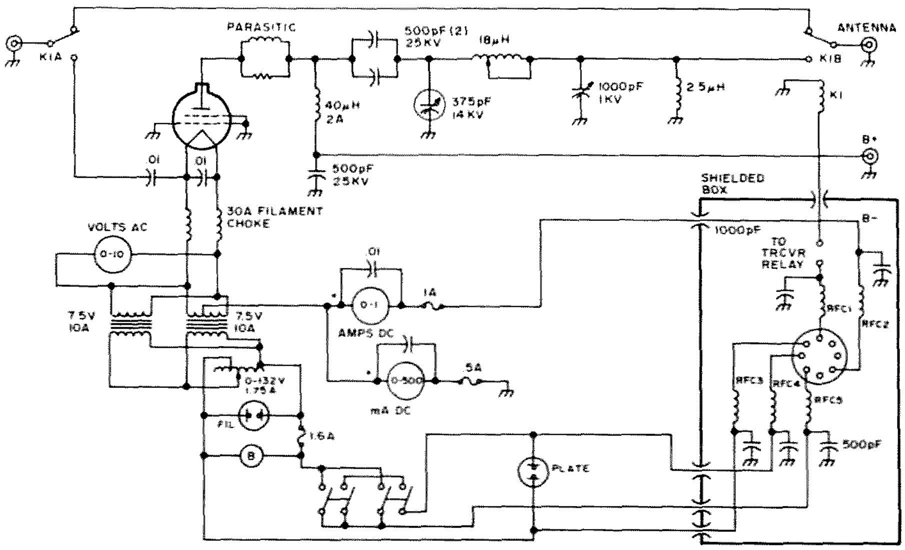


Fig. 2. Schematic of "Super Bottle" amplifier.

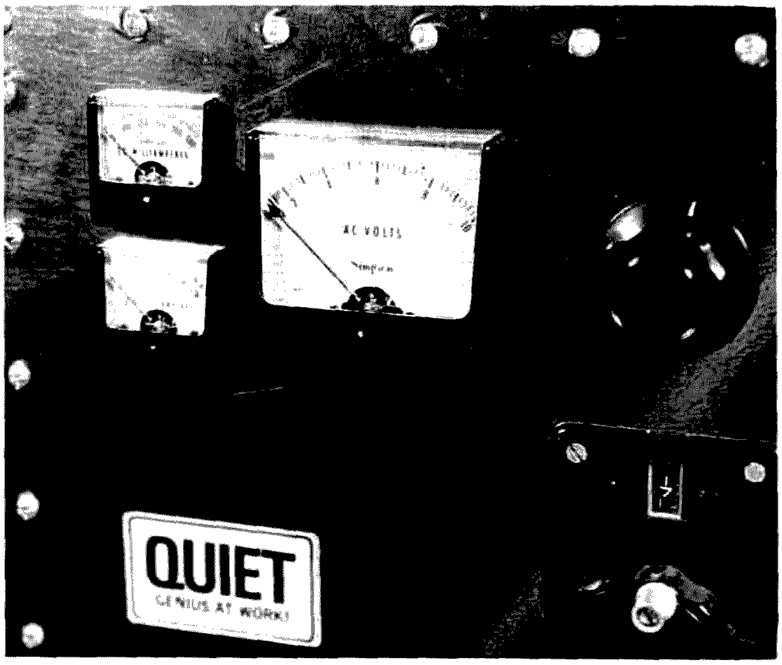
Tank Circuit

William Deane built the two Amp plate choke which is surrounded on one side by the tube and on the other by the stacked tune and load capacitors. The roller coil will provide about 18 uH maximum. The loading capacitor is not sufficient for 80 meters with the triode, and the coil is marginal for the tetrode on 80. For best results, Q = 12, the coil should have about 20 uH and the loading capacitor about 1800 pF.

Metering

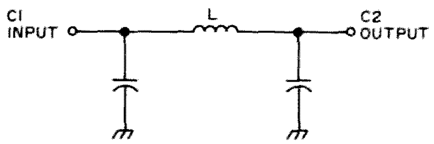
Separate meters for plate current, plate voltage, grid current, and filament voltage add considerably to the overall cost, but there are times when one needs all values at a glance. Fuses in the lines to the plate and grid current meters save meters. My first linear blew both meters when the B+ shorted through a faulty component. Since then test and "burn" trials have blown fuses instead of meters. The meters are bypassed with mica, not ceramic, capacitors, as the latter are not always reliable in rf applications. The meters are in the same compartment with the blower and all leads are "fed-through" with capacitors into the next compartment.



Detail of panel meters.

Power Supply

The power supply is enormous and very heavy! After the plate relay, the ac is fed to the variac, which is turned up slowly to avoid surging. The plate transformer, as well as the two chokes, is from a BC-610 power supply and is rated at about 5 kV at .5 Amp continuous duty. The full wave bridge rectifier has ten kV in each leg built of 40



Band	Input C1	Turns L	Output C2
80	–	16 of #18	470
40	512	13 of #16	322
20	337	9 of #14	213
15	247	6 of #13	190
10	227	4 of #13	190

The coil forms should be half inch slug tuned (look in ARRL Handbook).

Table 1. Chart of the input values for the 4-1000A.

Parts List

C1, C2 — 120 uF 3000 V dc isolated from ground.
R1, R2, R3, R4 — 80 kΩ 250 Watts.
T1 — 105, 115 V ac primary 2500, 2000, 0, 2000, 2500 volt secondary. Rated at ≈ 500 mills continuous duty in full wave bridge.
K1 — 24 V dc 15 Amp contacts.
Variac — 0-140 V ac 20 Amps.
Z1 — .01 at 400 V ac in series with 100Ω 10 Watts or arc suppressor.
Z2 — .001 at 25kV in series with 200Ω 25 Watts or arc suppressor.
RFC1-5 — 18 turns #14 enam. wire, close-wound, ½" dia.

1000 piv 2.5 Amp diodes and associated RC networks. The chokes are each rated at 11 Henrys at 500 mills and insulated at 10 kV, but just the same are in the negative lead. The oil-filled filter capacitors are insulated from ground, similar to electrolytic strings, since they are rated at only 3,000 WV dc and peak voltage is about 5,000. The bleeder resistance is a string of four 80k Ohm 250 Watt ceramic covered large economy size units. Two would do, but then the shack would need no heater either.

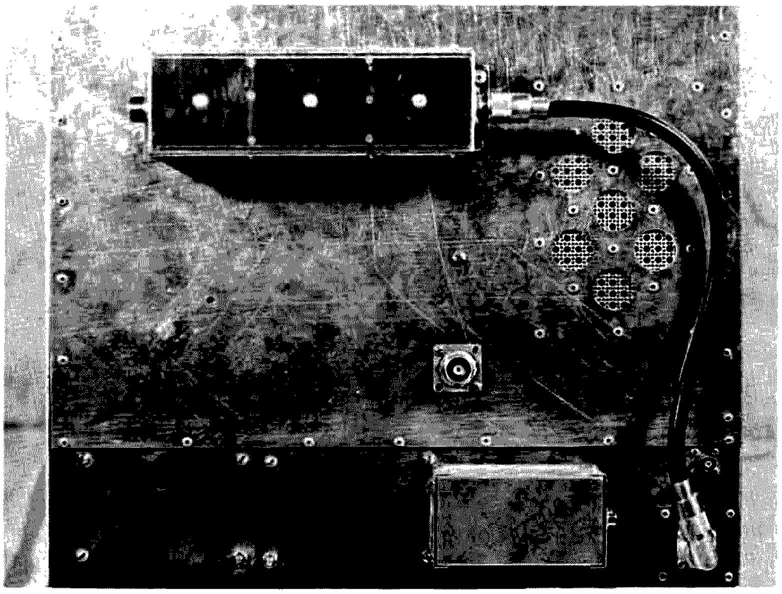
The chokes are tuned with an oil-filled .05 uF, 10 kV capacitor so that the bleeder can be small, yet the voltage doesn't soar when there is no load on the supply. Here is a simple way to tune a choke: LC = 1.77 (or close will do). The value of a choke, non-swinging, increases when the load current is low. Figure about two times rated value for good quality chokes. Thus, in this case, 1.77 divided by about 2 x 11 (two chokes in series) or 20 = .08 thus .05 is ok. The closer the better; experiment to get the best regulation. L is in Henrys, C in uF.

Control Circuitry

The wiring of the filament and plate relay switches is copied from Max Burggraff's design (note references). No matter which switch is thrown first, the filament is turned on, and both have to be thrown to energize the plate relay. The changeover relay is suitable for transceiver operation. A three pole relay would be useful for biasing the triode under idling conditions, but the 4-1000A only draws about 120 mills at 5 kV, not enough to bother the tetrode.

Miscellany

The components were arranged so that the leads are as short as possible, yet the front panel is not unsatisfactory. The meters are bunched to make shielding easier. I tried to cover a scratched front panel with a very shiny, gold contact paper. Other than the fact that the paper bunched up under the screw heads, it is tolerable. However, I won't do it that way again. The cabinet is built up around a steel chassis (for strength), plated copper. Other than the chassis all the sides are aluminum. I also used aluminum rivets where the joints would not restrict servicing.



Rear view.

Comment

"Super Bottle" works very well with either tube in the socket, though bias will keep the triode much cooler during standby. Efficiency is on the order of 60% on 20, 40 and 80 meters and less on 15 and 10, due to the less than optimum coil at higher frequencies. The linear is clean according to my monitor scope and the wattmeter indicates a quite noticeable difference over the transceiver. The on-the-air reports agree. I will be glad to respond to any correspondence accompanied by an SASE.

Acknowledgement

I thank the following: From Eimac, Salt Lake City, for the technical assistance, Vern Campbell K7BYQ and Erwis Isgitt W7SLC; friends who listened and suggested, Max Burggraff WA7AIA and Phil Bullock W7VEO; John Lloyd, Jr. WA7GWU who helped with suggestions throughout construction and testing; Fred Roberts WA7NKS, neighbor and photographer. I especially appreciate the tolerance of wife and children because the mess in the playroom stayed for long periods of time between cleanups. ■

"We Must Abandon Ship... Help..."

Miami FL 33155

It was cold and windy, that New Year's Eve, also a "straight key night." I went down to the shack and took the old 50 Watts rig from the shelf. This transmitter was built by my uncle in the early 1930s. I remember the many hours I spent in his shack, trying to tell the dots from the dashes.

The strong smell of the bakelite fired my imagination. I removed the dust from the 46ers and looked around for the power supply. I wondered if the old rig still worked.

An exciting idea came to my mind. How about using this transmitter on *straight key night?* It certainly would be interesting to find out the kind of reports I would get from the fellows.

I found the power supply and plugged it in and then proceeded to check the voltages with the VTVM. To my surprise everything was okay. I found the crystals and sets of coils for 80 and 160m in a box. The 40m coils were already plugged in the rig.

I hooked up the power supply and one of the 40m crystals. Before turning on the rig I took my grid dip meter and tuned the stages to the crystal frequency, then I hooked my Cantenna to the output.

The great moment came. I fired up the rig! The filaments glowed with a pale reddish color. The ammeter has a plug, and jacks to check grid and plate current where installed in the front panel. I plugged my old brass key in the proper jack and used my receiver with the antenna disconnected to check if the rig was working. I keyed and tuned the plate to a 50 mA dip. I moved the receiver's dial until a loud note came from the speaker. It was working! The old son of a gun was working! I couldn't believe my ears! For the on the air test I had to improvise a primitive antenna switch. This task took me only twenty minutes, but it seemed like an eternity.

Finally, I was ready to go airborne. I listened in the crystal frequency, and fortunately it was clear. I didn't want to step into anybody's QSO without invitation, so, with trembling hand I sent a QRZ and my call letters. I was used to using a bug and fumbled badly with the straight key. Nobody answered. Then I launched my first CQ. By the time I signed K my fist was getting the old feeling of the straight key. I switched the antenna to the receiver and searched for a signal. Nothing, except some familiar QRN. After my third or fourth try there came an answer. I scribbled his call in my pad and proceeded to switch the antenna. It was a 4 call, so he was not too far, but who cared if he was just around the corner? The great thing was that somebody heard the old rig! I gave him the RST report and the routine stuff, switched the antenna and listened.

"Sorry OM but you have something that sounds like key clicks. Your RST is 569 with QRN. The clicks are not really bad and I hope you can fix it."

I told him the kind of rig I was using and that I was going to try to solve the problem. After signing out and wishing him a Happy New Year, my XYL came into the shack like a tornado: "You are messing up my TV.

You told me that would never happen again! Guy Lombardo has streaks all over his face!"

"But, honey bunch," I told her, "the old man has been playing with his band for quite a few New Year's Eves, and it's normal to have those wrinkles in his face. . .maybe he needs a face lift. . ." It was pretty lame.

"This is not the kind of wrinkle you can fix with silicone. . .maybe one of your funny looking filters. . ."

I knew she was right. So back to the old drawing board. With no shielding, and all the long leads scrambling like snakes over the wood board, the old rig was radiating all kinds of parasitic oscillations.

I wanted to work straight key night and I knew to dress those leads and fix the trouble would take hours. But I decided to do it. A couple of capacitors added to the filament of the oscillator tube and shortening the lead to the screen capacitor did the job. I was back on the air in less than an hour.

I switched to 80m and worked stations as far as New York. I was having a ball every time I told the fellows about the old rig. The clicks reported in my first QSO were almost nothing after placing a capacitor shunted by a resistor across the key contacts.

After signing out with a fellow in North Carolina I heard my letters being called. It was a very weak signal. I couldn't copy his call letters after I signed "QRZ?"

I plugged the "cans" and tried to retune the receiver. Holding the "cans" to my ears I heard my call letters again and broken words: ". . .are. . .danger. . . please. . .help. . .This is maritime mobile. . ."

The QRN was tremendous. I couldn't believe my ears. It had to be a prank. A ship in distress and calling in the ham bands? Impossible!

I banged the antenna switch in the transmitting position: "Where are you? The name of the ship, please?" I repeated the message a few times very slowly and signed "BK."

The answer came back, "Ship name is. . . bound for Cape of Good Hope. Position is. . .° West and. . .° South. We must aban-

don ship. . .five feet of water in the bilge. . .please contact. . . Guard. . ."

And the signal faded away. . .

I fumbled with the knobs trying to pick up the weak CW signal. The erratic dash and dots came back:

"He is beserk. . . will kill all of us. . ."

A burst of static whipped him off.

Holy Neptune! What was going on on that ship? Was he talking about the storm or a member of the crew?

Through the QRM the CW signal came back once more. "The skipper is dead . . . please call. . . that man is crazy. . . BK. . ."

I slammed the antenna switch to transmit. "The name of the ship and position again, please!" repeated the same many times, signing my letters and K.

"Position is . . . °South . . . name of the ship is 'Flying Dutchman' . . ."

The "Flying Dutchman"? Somebody must be pulling my leg. Or was it a real ship whose owners had had the bad taste to name their ship after that legendary ghost?

Again and again I tried to contact my evasive operator without success.

I went to bed and the lights of the New Year found me with my eyes open, looking at the ceiling. Had to be a prank, I told myself . . . ■

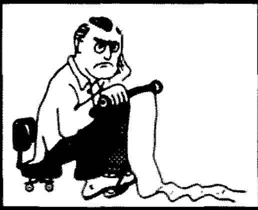
#184 FEB 1976

73 Magazine (where the action is) is published monthly by 73, Inc., Peterborough NH 03458 (a good place to live). Subscription rates are a ridiculously low $10 for one year worldwide, $17 for two years, and $20 for three years (the buy of the year?). Second class postage paid at Peterborough NH 03458 and at additional mailing offices. Phone: 603-924-3873 (hey, don't call much after 4:30 pm EST, okay?). Microfilm edition – University Microfilms, Ann Arbor MI 48106. Tapes – Science for the Blind, 332 Rock Hill Rd, Bala Cynwyd PA 19904. Say, fine print readers, 73 is growing rapidly and sure could use a couple more active hams who are technically ept and maybe can write. You won't find a much more fun place to work . . . and money isn't everything, right?



NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

ANY PUBLICITY IS GOOD PUBLICITY

So the saying goes, anyway . . . just be sure to spell my name right. Apropos of the bum dope spread by jealous competitors re the bonus November/December issue of *73*, which 256-pager came as a terrible shock to other publishers . . . heh, heh.

One club bulletin editor and two readers got so unnerved over the reported rip-off by *73* that they wrote about it. The only rip-off was the spurious report that subscribers might get only eleven issues for the year.

When it became obvious that nothing was going to stop ARRL in its madness in going to the larger format for *QST* . . . and that their satellite was also going to make the change, we said what the hell, it makes no sense from any standpoint, but if that's the size ads are going to be, then *73* has to fit the ads or else *73* is out of biz. Okay, as long as we're going to change size, why not get the jump on our slower compatriots and come out in December with the first large magazine and drive them crazy.

The first plan was to have the November and December issues of *73* on their regular schedule and at the old size, but come out with a special bonus issue in between the other two in the large size . . . a "Shape of Things to Come" issue. The ad department started selling the idea to advertisers and before long we found ourselves way over our heads in magazine. Our staff had more work than they could handle, with three big issues coming out at two week intervals. My solution to the jam-up was to put the November and December issues together and make that one issue. This would fill out the binders with the old smaller size magazine. The "Shape" issue would then be the January issue, but would come out on the December issue schedule.

Even so, the work was enough to put the November/December issue about a week behind its schedule and the January Giant issue two weeks behind. We'll catch up in a couple of months if we don't think up any new ideas for big issues and get the ad department triggered into a selling spree again. The more ads, the bigger the magazine, obviously.

My plan to call the January issue a December/January issue just to further confuse everyone was vetoed. Spoil sports.

WHERE COMPUTERS ARE AT

Those readers of *73* who are into microcomputers are in on the ground floor of something new and exciting. I don't think many people realize how incredibly new the low cost computer field actually is . . . in point of fact it just got started in 1975 with the introduction of the MITS Altair 8800 processor.

By way of comparison, a computer system which might have cost $1,000,000 in 1970 was down to about $100,000 by 1974 by virtue of the application of ICs to computers. These medium priced systems were called minicomputers . . . they were mini in size, but their capability wasn't much different from most of the earlier maxis. Then came the computers-on-a-chip . . . the Intel 4004, the National IMP-16, the Intel 8008, the 4040 . . . and finally the Intel 8080. Motorola came up with the M6800, Fairchild with the F8, National with their PACE, General Instrument with a C1600, and MOS Technology with the 6501.

The micro chips revolutionized the computer industry again, resulting in the microcomputer or microprocessor, as it is often called. As with the mini, only the name and size had changed . . . the job these micros could handle were about the same as the bigger computers . . . but now the price for a system had dropped from $100,000 to about $10,000.

Have we reached the end of this progression? Not by any means. The chip people are still busily at it, designing cheaper and cheaper microprocessors . . . the latest is the $25 6501 chip which is a direct replacement for the much more expensive M6800 . . . and, as engineering costs are amortized, we can look for these costs to drop further.

The cost of peripherals will also drop as firms gear up for mass production of interface and control chips which will replace the IC-laden circuit boards of today. One-chip video display generators will probably bring the cost of the video keyboard down to the $100 range . . . like a black and white television . . . though that may take three or four years. Right now anyone that comes out with a $400 video keyboard will make millions of dollars . . . until the $350 unit comes out.

None of the present day tape storage systems are ideal for small computer systems and the race is on to invent a mass memory storage system which is geared to the low cost computer. Small businesses and homes don't need very large storage systems, nor do they need lightning fast service, so a tape system which would allow you to get your data in a few seconds would cut the mustard . . . a good trade off against price.

There are fantastic opportunities in the small computer market for making large gobs of money. There will probably be more computers sold in the next year than there are in existence in the world today . . . and maybe five to ten times that many in the next year. The hobbyist of today who gets to know the field and is able to take advantage of what he knows could be the mogul of tomorrow.

By way of getting used to how early we are in the field, as of late summer 1975, to my knowledge, even MITS had not yet started shipping complete computer systems with floppy disk operating units . . . they were close to it. Remember that MITS, as of this date, was the *only* supplier of micro systems in the country. Several others were about ready to go. By the time this reaches print I expect that there will be at least three, perhaps four, firms supplying operating microcomputer systems . . . hopefully with working floppy disk memories. Floppies will have to hold until one of the mentioned tape systems is invented. Floppies are okay . . . a little limited in capacity . . . and expensive by hobby standards . . . $1000 to $2000 range.

HAMMING IT UP ON COMPUTERS

How will we be using computers in amateur radio? Will they further reduce the quality of contacts, making them even more mechanical than today . . . if that is possible?

I realize that it is popular to bad mouth developments such as this, but the fact is that my experience indicates that it may well be that amateur radio never had it so good. Those of us who have delved into radio Teletype communications are not unaware of the fascination that this mode holds. We also are probably aware of some of the reasons for the excitement and fun of RTTY as compared to CW and SSB.

There are some basic problems involved with radiotelephone communications to which we have given too little consideration. After spending our childhood years learning

how to talk with people we can see and hear . . . getting feedback from them as we talk in the way of grunts, yesses, nods, etc., and even getting these during telephone conversations . . . we are unprepared to handle the prospect of talking to someone we can neither hear nor see. We are at a loss for words . . . known as mike fright in beginners . . . known as incredibly boring contacts and deadly routines in older timers . . . the 10-4 of the CBers . . . the endless repetitions of some amateurs . . . the meaningless descriptions of stations, weather, and such.

Most of your life patterns are well set by the time you are five, and that includes your ability to talk to people you can't see or hear. The result is that the brain boggles and rational conversation is virtually impossible. This may explain the difference between talking to hams in person and trying to work up anything more than an exchange of pleasantries over the air.

With RTTY we find that we have a lot more time to engage the brain and give some thought to what we are trying to say. The result is that in general our communications are a lot more interesting . . . more like a series of letters being exchanged than talking. It is just possible that amateurs using computers for contact would go this route. They probably would even go one step further and keep a tape of their better efforts so they would be available during later contacts.

Just imagine what an interesting story you could work up for a contact about a recent trip . . . a DXpedition . . . or some good DX worked . . . some adventures in putting up your tower . . . stories about how a beam works . . . you could put real life into your contacts.

Let's move the clock ahead and imagine a contact in 1978 . . . it is not your computer working his computer, but it is something like that. You would get in touch and your screen would have the hello and a list of some things you might be interested in talking about . . . perhaps a list of some things you might be interested in talking about . . . perhaps a list of some stories he has on tap for you. You give an okay to the tower story and immediately your screen comes up with the tale of how he read about this tower . . . got the parts to build it . . . got it all together and then couldn't get it raised! Your screen, when you give the keyboard a "go" gives you a couple pictures of the chap and his friends trying to raise the tower on slow scan. Then more story when you give him another "go."

Does your friend have to sit there and wait while you do all this? No, of course not . . . he has gotten the same type of stuff from your system and is busy watching the story and pictures you have on tap for him.

Won't all this take up a lot of the band? Probably not . . . the chances are that hundreds of contacts will be carried on in short bursts on a single channel . . . possibly with a fixed frequency receiver . . . or it may come down to several fixed channels such as on FM today.

On the other hand, it might not work out like that at all . . . but it could.

COMPUTERMANIA

Despite a whole lot of effort, I am still an utter neophyte in the computer field. I want to establish that before I tell you about computers. Okay?

Now that I am no longer involved with *BYTE* magazine, but still haven't lost my enthusiasm for computers and their future in Amateur Radio, I'd like to do everything I can to encourage them's as what knows to write for us'n's which wants to know . . . for *73*.

Now before you start to write, you computer expert, you . . . I want to lay on you a little thought . . . the great unwashed of us out here don't even speak your language yet. We don't know a compiler from an assembler. Oh, we really want to know and we're looking for you to explain the whole works to us in simple terms which we can understand, not in computer jargon. Just take a look at the beautiful job Larry Kahaner has been doing in explaining the basics of digital design and you'll get the idea of what we need.

We want to know about computer design, ham applications of computers, the differences between the various systems such as the 8080 based processors, the 6800 based, PACE based, etc. Sure, we know that in the end all of them will do just about anything we want them to, but we also want to try and understand what the differences are and what these differences mean to us.

We want to know about how to use our teletype machines . . . our television typewriters . . . our cassette recorders . . . how to interface other computer equipment and use it . . . how good or bad some of the new hobby computer equipment is and what we can or can't do with it . . . stuff like that.

We want to get a general idea of what the major computer languages mean, why which are used and when, which we should learn and why, and so forth. We want to have an understanding of what people mean when they refer to Fortran, to Basic, to Cobol, to RPG, to PL, and other common program languages.

We want to be able to hook up computer systems and use them . . . for games . . . for hamming . . . perhaps for printing out the schedule of Oscar 7 or the times of possible acquisition of Oscar for active Oscarites . . . moonbouncers want to know where the moon is or even have a computer point their antenna . . . and who of us would not like to be able to keep track of all our ham contacts in a computer system?

We want to know where we can get programs for use in our computers, from the simpler systems such as the HP-65 on up to Altair 8800, Sphere 6800, SWTPC 6800, Godbout PACE, etc. The hobby computer field shows no sign of slowing in its growth.

So there you have it . . . we need articles. Writing for *73* is simple . . . double space type it with generous margins, a sketch of diagrams will do (but be very careful to include everything possible), and the best photos possible. If you have trouble with photos send the stuff here and we'll take 'em. If you have a source of PC boards for construction projects be sure to let the readers know . . . if not we'll try to find one. We also like to have a negative of PC boards available for interested readers if possible.

The best part, perhaps, is that we pay and pay generously for articles. Not only are you able to share your work with others and bring them fun and happiness, you also get paid . . . and you get well known, too. Ask Pete Stark and other regular *73* authors about that! If publishing will help you in your work or to get a better job, this is a good medium. Of the ham magazines which pay for material, *73* has by a wide margin the largest circulation, no matter what you may have read in the way of half-truths (well, 39.5% truths) elsewhere. You want your articles to get the widest distribution, don't you?

Get busy, then, and teach us something about computers . . . and try to remember what it was like to not know computer language when you write for us.

I/O

Articles on digital techniques and microcomputers will be identified in *73* from now on (see page 52) with an I/O mark . . . this means Input-Output. A computer can't do anything unless there is something feeding it input . . . and there is something for it to feed output to. It seems like a nice digital type term.

Continued on page 15

LETTERS

On Your Marker

I have been etching my own circuit boards for quite a few months now and really enjoy it.

Since my boards are for one-of-a-kind projects, I have been using Datak's dry transfer etch resist. However, there are times when a pen would be handy for large areas or long lines. I purchased an etch resist pen and was very unhappy with the results. I decided to conduct an experiment to determine the best pen for this purpose. The results are surprising. Here are the results with the best listed first and the worst listed last:

1. El Marko Permanent Marker
2. ADI Ink Marker
3. Archer Etch Resist Lacquer
4. Carter's Marks-A-Lot
5. GC Electronics etch resist pen
6. Eagle Marker

The Lacquer is not a pen but a bottle with brush, and is hard to use.

Another interesting factor is that the number 1 and 2 markers are less than half the price of the etch resist pen and are readily available in most discount stores.

Barry N. Shiffrin WB2FPG
Endicott NY

S-40 Search

I am looking for a schematic on a Hallicrafter Model S-40 receiver. Even the specs on the main power transformer would help.

Help Clearinghouse

I note the apparent contradiction between those who are experiencing difficulty in finding assistance in obtaining an amateur license and those who are only too happy to provide this needed assistance. From this situation, the need for these two groups to get together becomes quite clear. Why not start a sort of clearinghouse of names of clubs and individuals who are willing to provide assistance? A prospective amateur would only need to call or write this clearinghouse, which would see to it that he was contacted by a local ham/club for assistance. In reality this should be a function of the ARRL, but it is quite apparent they have not fulfilled this need. This would be an ideal function for some club to provide. In the meantime, I would like to volunteer my services to function in this role. Any individual/club who is willing to serve as a helper, anywhere in the country, is welcomed to call or write me to start a list. Any potential amateurs are also welcomed to contact me and I will strive to find someone to provide assistance to you.

Good Godbout!

I want to tell you about one of your advertisers . . . Bill Godbout . . . great! Some time ago I ordered some parts from him, and would you believe I got 1 week delivery? That's what I call service. You always hear about the "bad" guys – I just wanted to let you know about a "good" one.

Chuck Young WB8TDW
Waverly OH

Rich? – or Crazy?

My November/December issue arrived a few days ago and I haven't put it down since. My mouth was hanging in disbelief as I read WØSYK's account of his antenna system. It must be nice to be rich – or is it just crazy? – hi.

I also enjoyed W1BNN's article about his Germany days. I *always* enjoy the old timers' stories or any story about an unusual occurrence – particularly involving ham radio. I think it is great that *73* encourages this type of writing, as I find it a very enjoyable interlude from some of the monotonous technical articles found in some of the other mags.

Well, keep up the good stuff!

Mark Morgida WA1SSW
Billerica MA

CU on 20

I would like some information about, or to see published, an article on curing the interference from the 15 kHz sweep circuits in TV sets. This gets really strong in ham receivers on the 160 and 8 meter bands.

Also, how about an article on how to build a battery-operated QRM locator, using loop antenna (omnidirectional), with meter, so a person could go directly to the noise source? Have *73* from the first issue, and always enjoy it. CU on 20.

Glenn Lay W7ADS
Yakima WA

At the Forefront

I'm grateful to *73 Magazine* for being 100% behind its products. I had some trouble with a 20 wpm code tape, wrote and requested that it be replaced, and two weeks later I received a replacement.

Services such as this will keep *73 Magazine* at the forefront. Thank you.

Jeffry M. Blackmon WB2UYI
North Tonawanda NY

HP-45 Fun (Cont.)

I am writing in regard to another letter which appeared in the Letters column of the October issue of *73*. It is entitled HP-45 Fun from Sig Peterson III of Portland, Oregon.

The time indicated by the HP-45 is NOT accurate. On the HP-45 I own, the timer indicates 52 seconds after 60 seconds have elapsed. This has been verified by checking against several different clocks, both electrically timed by the generators and by quartz crystals (which are in use here on the radar site), and by checking with WWVH.

This has presented no major problem as the 8 second error is constant and, as long as I can remember the error, I have been able to use my HP-45 as an elapsed time indicator.

There is another set of presets which do the same thing. They are as follows:

1. Press the "RCL" button.
2. Simultaneously press 3 keys: "R ↓", "STO", and "CHS". After obtaining the display as shown in Mr. Peterson's letter, the remainder of the operations are the same as shown in the letter.

As I work with several engineering types here in the radio shop, and the White Alice Communications System section, I was able to borrow an HP-35 and an HP-55 to try these programs on. Neither of the other calculators will duplicate the function.

The HP-XX series of calculators are

visiting views from around the world

The Time Has Come

The expansion of the phone bands has been discussed many times in the past, but very little or nothing has been done to change things around. We have today more or less the same distribution of segments for CW and phone that we had forty years ago. In the last decades, ham radio experiments and advances have caused an extraordinary transformation. To mention a few: SSB, FM, VHF, UHF, RTTY, ATV, SSTV, facsimile, satellites, moonbounce, etc., etc.

With all these modes and fields to research and experiment, the spectrum of the bands has remained the same as when CW and AM were the prime modes of communications.

The time has come for a complete overhauling and restructuring of the ham bands. We are a technology-oriented group and it is natural that we must cope with this problem in a technological way. It is very simple to feed an appropriate computer with all the data and information on the number of hams, modes of operation, percentage of time on the air, most used bands and frequencies, traffic handling, foreign reciprocal licensees and their operation habits, etc., and we can come out with a plan for the appropriate distribution of band space. You can allocate ten CW signals on the same space as one SSB, and logistically the CW segment in the bands only needs to be a fraction of the space for SSB. RTTY with narrow shift is another mode that does not take too much space.

If you take a good look at the 20 meter band, one of the most popular and crowded, you will find that American amateurs (Advanced and Extra) can work phone only from 14.200 to 14.350 (150 kHz), while the spectrum for CW is from 14.000 to 14.350 for Extras and 14.025 to 14.350 for Advanced and General. That means that you can work the whole band on CW, but only a fraction on phone. Why this strange rule if only a small fraction of active hams work CW?

I am a CW man myself, I have an Extra ticket, and think that CW is one of the greatest and sure forms of communication, but I am not a fanatic and like to live with reality.

Somebody told me that the reason for the phone band limitation was an old international agreement so we don't QRM the DX stations with our powerful linears. I think decades ago this was a very gracious gesture by the American hams to their colleagues abroad. But the situation has changed dramatically. Today these fellows are using full gallons, and in America we have thousands of reciprocal licensees that devote their time to phone patching and handling traffic for their countrymen in the USA. I am not against the reciprocal licensing. I think it is wonderful. The only trouble is that this traffic is jamming our narrow phone bands precisely in the lower sectors. Please, take the trouble to tune the 20 meter band from 14.200 to 14.250 and you will hear the traffic going on.

But here is what happens when you need traffic for Cucamanga. You heard a station on 14.155 broadcasting from Cucamanga, but you couldn't call the gentleman and ask him to phone patch Aunt Myrtle, because American hams are not allowed to work phone under 14.200. You can't even call them in CW, because most do not know code. Now, on the other hand, when the gentleman in Cucamanga needed Miami, the only thing he had to do is come over the 14.200 and ask us to phone patch Aunt Juanita. And we generally do it. Noblesse oblige.

I don't think this is a fair situation. And I don't believe that it is reciprocal and just.

We've come a long way. Ham radio is not spark gap anymore. The tremendous strides in technology, the diversification of modes, the advance of the state of the art, call for a fast revision of band allocations and the time to do this is here, NOW.

Albert H. Coya WB4SNC
Miami FL

Sweet Mystery of Life

As it may come to any neighborhood, scandal trailed across the ridges recently and one of the local QRPers ran off with a young widow to live in idyllic bliss high in the ranges. Finally, one of the local QRPers had to look them up, and he came back with the sad report.

"It sure is something," the QRPer reported. "Here he gets up every morning at the break of day to watch the sunrise and his bellowing of 'Ah, Sweet Mystery of Life at Last I've Found You' goes echoing through the canyons. How do you figure these things happen to a fine fellow? How do they happen?"

We had to admit that we had felt some concern over these events and finally had to ask the inevitable. "Do you think he's happy?" we said, and the QRPer snorted.

"How could anyone be happy," he said, "standing outside in the morning sunrise and yelling, 'Oh, now I know the secret of it all'? And all this time the morning DX path will be fading and he has missed all the DX again. How could one be happy with that?"

Son of a Gun, we had to admit that he had a point there.

* * * * *

Last week we came across another one of the local QRpers and we just had to ask how he had done in the recent DX Test. Maybe we should have talked of other things: It was not joy that crossed the face of the QRPer, and we had to listen to his story.

"I figured that in this contest I would aim for new countries," he explained, "and I latched on to one that I needed early in the test. But I called and called and called. And I never did work him, I never worked him at all."

The QRPer paused under the weight of the emotions that raged within, but finally he pulled himself together and was able to continue. "I never did work this fellow I was calling. I never got him to come back to my call. Chased him for the whole weekend but things just did not work out."

We were properly sympathetic, for we also have known the lonely nights of frustrated DXing. "Who were you calling?" we asked, and that was another mistake.

The QRPer shrugged. "UP2KHZ was the station I needed," he mumbled. "He kept giving his call and I kept calling him all weekend but I never did work that Lithuanian. The first UP2 I've heard in years. The first in years."

You know something? We thought this over for a bit, but what could one say in a situation like this. Only that often the chase is long and the quarry elusive. And sometimes one will chase one thing while thinking it is something else. And wishing to take from no man his dream, we said nothing at all.

Give not your sympathy to the chaser of the elusive UP2s, he was not the first to hear the call . . . once there was a UFØOL on Franz Josef . . .

WATT Award

TIARA is now offering an award for working ten TIARA members within a year, beginning August 1975. Five of the ten members must be non-Japan stations. Send a self-addressed envelope with sufficient IRCs to TIARA, 22-5 Oyama-cho, Shibuya-ku, Tokyo 151, Japan, for a list of call-signs to look for. QSLs and 500 Yen (or equivalent) should be sent to JA1ADN, Fred N. Ihara, of *CQ Magazine/Japan.* His home address is: 8 - 4 Tokyu, Matoba, Kawagoe 350 Japan.

STRAIGHT KEY NIGHT

Starts: 0100 GMT Thursday, January 1, 1976
Ends: 0700 GMT Thursday, January 1, 1976
(Remember, this is actually Wednesday, December 31 local time.)

Suggested frequencies are the areas of 060 to 080 kHz up from the bottom edge of the band on 80-40-20, 10 kHz up from the bottom edge of the Novice segments. Work CW only using a straight key. Bugs, keyers, CW keyboards, etc., are not allowed. Use "SKN" in place of "RST" when exchanging signal reports.

REPORTS:
Immediately following straight key night, send a list of the calls of the stations worked along with your vote for the best fist heard that night (you don't have to work him). Send to: American Radio Relay League, 225 Main Street, Newington CT 06111.

Check the December issue of QST *for any last minute changes in the contest rules.*

CALENDAR

Jan 1	Straight Key Night
Jan 3 - 4	ARRL VHF Sweepstakes
Jan 10 - 11	CD Party – CW
Jan 14 - 15	DX-YL to NA-YL Contest – CW
Jan 17 - 18	CD Party – Phone
Jan 17 - 18	QRP – Winter – Contest
Jan 24 - 25	Simulated Emergency Test
Jan 28 - 29	DX-YL to NA-YL Contest – Phone
Jan 31 - Feb 1	French Contest – CW
Feb 7 - 8	ARRL DX Contest – Phone
Feb 13 - 15	QCWA QSO Party
Feb 14 - 15	10-10 Net Winter QSO Party
Feb 21 - 22	ARRL DX Contest – CW
Feb 21 - 22	YL-OM Contest – Phone
Feb 28 - 29	French Contest – Phone
Mar 6 - 7	ARRL DX Contest – Phone
Mar 6 - 7	YL-OM Contest – CW
Mar 14 - 15	South Dakota QSO Party*
Mar 20 - 21	ARRL DX Contest – CW
Apr 3 - 4	Florida QSO Party
May 1 - 2	Helvetia 22 Contest (H22)
June 4 - 7	IARS/CHC/FHC/HTH QSO Party
June 26 - 27	ARRL Field Day
July 3 - 4	QRP – Summer – Contest
Aug 14 - 15	European DX Contest – CW
Sept 11 - 12	European DX Contest – Phone
Nov 5 - 8	IARS/CHC/FHC/HTH QSO Party
Nov 13 - 14	European DX Contest – RTTY
Nov 14	OK DX Contest

*Please note the change in date for this contest.

If you have any information on a contest that is not listed, please let me know as soon as possible, and preferably at least three months prior to the contest date.

ARRL VHF SWEEPSTAKES

Starts: 1400 Your Local Time, Saturday, January 3, 1976
Ends: 2400 Your Local Time, Sunday, January 4, 1976

Complete rules for the 29th VHF Sweepstakes can be found in the December issue of *QST* (please check for any last minute changes in the rules). Briefly, the rules are as follows:

All amateurs operating on or above 50 MHz are invited to participate. Contacts between stations in different time zones can be counted only when the contest period is in progress in both zones. Foreign stations may only work stations in ARRL sections. Crossband work is not allowed as well as retransmitted signals (repeaters). Contacts with aircraft mobiles cannot count for section multipliers.

EXCHANGE:
QSO Number, precedence (A = less than 50 Watts input power), your call, CK = last 2 digits of year first licensed, ARRL section or country.

SCORING:
Score one point for each exchange sent and each received (max. 2 points per QSO). Each section counts as a multiplier only once regardless of band and no more than one foreign country may be claimed as a section multiplier. Yukon-NWT counts as a separate multiplier. Final score is the total number of QSO points times the total number of sections plus 10.

LOGS:
Official logs may be obtained from ARRL. Send contest logs and summary sheet to: ARRL, 225 Main Street, Newington CT 06111.

DX-YL to NA-YL CONTEST

CW
Starts: 1800 GMT Wednesday, January 14, 1976
Ends: 1800 GMT Thursday, January 15, 1976

Phone
Starts: 1800 GMT Wednesday, January 28, 1976
Ends: 1800 GMT Thursday, January 29, 1976

Sponsored by the YLRL, the contest is open to all licensed *YL* operators throughout the world. Contacts with OMs and net contacts do not count. General call is "CQ DX YL." All bands may be used but no crossband operation is allowed. Stations may be worked and counted once on each band and mode. Phone and CW contacts will be scored as separate contests, so submit separate logs.

EXCHANGE:
QSO number, RS(T), country or state.

SCORING:
Each QSO counts one point. Multiply the number of QSOs by the number of states or countries worked. If running 150 Watts input or less on CW and 300 Watts PEP or less on phone, multiply the total score by 1.25 (low power mult.). Your logs must show the input power you are running.

LEGAL CONTACTS:
DX-YLs will include Hawaii and may contact all of the North American continent which includes the states and Canadian provinces. Alaska YLs will be counted as DX but may not contact the Western Canadian provinces of VE5, VE6, VE7 and VE8. Alaskan YLs may contact Hawaii, the states, or the Eastern Canadian provinces. Contestants in the North American area may score contacts with DX stations, including Hawaii and Alaska (except as noted above). The Western Canadian provinces VE5 through VE8 may not contact or count Alaska as DX.

LOGS:
Entries in logs must show band worked at time of contact, time, date and transmitting power. Please print or type and use separate logs for phone or CW. Copies of all logs showing claimed scores and signed by the operator must be postmarked not later than February 5, 1976 and received by the contest manager not later than February 19, 1976, or be disqualified. Send logs to: YLRL Vice President, Beth Newlin WA7FFG, 826 W. Prince Rd. – 06, Tucson AZ 85705.

AWARDS:
Trophies will be awarded to the first place winner in each category, a plaque to the highest combined DX and NA scores, and certificates to the second and third place DX and NA winners.

QRP-WINTER-CONTEST

Starts: 1500 GMT Saturday, January 17, 1976

Ends: 1500 GMT Sunday,
January 18, 1976

The contest is organized by the DL Activity Group-CW. Work 15 hours maximum during the 24 hour contest period, with no more than two pause periods. Select up to 5 bands from 160 to 10 meters. General call is "CQ QRP TEST." A station is not handicapped if CO/VXO control *and* VFO control are used on the same band or the input power of a commercial rig is reduced to below 2.5 Watts. QRO stations – same rules, but work only QRP stations and sign as ". . ./QRO"; scoring is the same.

EXCHANGE:
RST, QSO number, and input (1 to 9). Add "x" if transmitter is CO or VXO-controlled. Example: 579 005/8x.

SCORING:
QSOs with all stations are valid unless running QRO, then only QSOs with QRP stations count. Contacts with your own country count 1 point, own continent = 2 points, DX = 3 points, and score 3 additional points for a QSO with another QRP station (4-6 pts.). Score additional handicaps as follows: 1 handicap point for each station using below 3.5 Watts input or crystal controlled transmitter. Maximum handicap is 4 for any QSO. Both stations multiply QSO points times the handicap points plus one (QSO pts. x 5 max.) to find total QSO points for that contact. Multipliers are as follows: own continent = 1, DX = 2 points per band and country according to the latest DXCC list, but call areas in JA, PY, VE, VK, W and ZS count extra. Final score is total QSO points (including handicap pts.) times the total multiplier.

LOGS:
Send entry including a "mini-log" to: Hartmut Weber DJ7ST, D-3201 Holle, Kleine Ohe 5, Fed. Rep. of Germany. Logs should be sent no later than February 15, 1976.

1976 FRENCH CONTEST

CW
Starts: 1400 GMT Saturday,
January 31, 1976
Ends: 2200 GMT Sunday,
February 1, 1976

Phone
Starts: 1400 GMT Saturday,
February 28, 1976
Ends: 2200 GMT Sunday,
February 29, 1976

EXCHANGE:
French stations will send RS(T) and number of department. All other stations send RS(T) and QSO number.

SCORING:
Score 3 points for each QSO with French stations or French speaking countries (DUF, ON, HB, LX, VE2, OD, HH, 3B, 9U-Q-X). Score 10 points for contacts with F8REF, department ØØ.

MULTIPLIER:
Count one multiplier for each different department, ON province, HB canton, and French speaking country per band.

FINAL SCORE:
Final score is the total number of QSO points times the total multiplier points.

LOGS:
Send logs to: Lucien Aubry F8TM, Rue Marceau 53, 91120 Palaiseau, France.

RESULTS

RESULTS OF THE 1975 WASHINGTON STATE QSO PARTY

The following list shows all stations that received certificates for their participation in the contest. VE7ZZ/W7 was first overall in Washington and KØGJD/6 was the first overall for outside Washington.

Alaska	KL7HDX	1,170 points
Arizona	K7AL	1,978
California	KØGJD/6	9,242
	W6KYA	1,590
Colorado	KØQIX	2,124
	WBØGEX	1,944
Connecticut	WA1KMP	360
Florida	K4HWW	2,204
	WB4OGW	2,200
	W4LIN	1,232
Georgia	WA4APG	540
Illinois	W9WR	702
Iowa	WØPRY	1,620
Kansas	WBØIAQ	1,224
Kentucky	W4KFB	572
Maryland	W3YHR	204
Massachusetts	W1AQE	1,066
Michigan	W8CNL	1,120
	WB8PFB	814
Minnesota	WBØMAO	540
Mississippi	W5RUB	520
Missouri	WØQWS	1,824
New Jersey	K2JFJ	190
New Mexico	WA5YTX	464
	W5TIL	460

JAPAN	JA2HGA	280
	JA1WVK	266
	JA7KE	256

Washington State Winners

W7GHT/M7 won first place from the following 12 counties: Benton, Chelan, Columbia, Douglas, Ferry, Franklin, Kittitas, Lincoln, Okanogan, Pend Orielle, Spokane, and Walla Walla.

Other winners are as follows:

Cowlitz county	WA7LQQ, WA7PMW	13,440 points
	W7FGD/7	130
Grant county	W7GYF	9,045
King county	VE7ZZ/W7	79,424
	W7YTN	27,144
	K7JCA, W7EXM and WA3DVH	19,482
	WB5NLE/7	14,617
	WA7FHG	12,150
	WA7UQG	11,660
	WA7VBT	11,186
Kitsap county	K3USH/7	4,284
Mason county	W7IEU, WA7FKM	3,102
San Juan county	K7NHG	6,437
Snohomish county	K7NCG, WA7SLO and K7UWT	46,787
	WA7ZSJ/7	126
Wahkiakum county	WA7BSQ/7	576
Whatcom county	W7EKM	3,140
Whitman county	W7YH	29,412

ARRL DX COMPETITION

Phone
Starts: 0001 GMT Saturday, February 7, 1976
Ends: 2359 GMT Sunday, February 8, 1976
Starts: 0001 GMT Saturday, March 6
Ends: 2359 GMT Sunday, March 7

CW
Starts: 0001 GMT Saturday, February 21
Ends: 2359 GMT Sunday, February 22
Starts: 0001 GMT Saturday, March 20
Ends: 2359 GMT Sunday, March 21

These rules were taken from last year's contest, since the ARRL has not released information as of this writing. Check the December issue of *QST* for complete rules and any last minute changes.

Briefly, the rules are as follows: All fixed station amateurs, worldwide, are invited to participate. All amateurs in the 48 states and Canada will try to work as many stations in other parts of the world as possible. All other stations will work only W/VE stations. Entries may be in either the CW or phone section; each is scored independently. Entries are further classified as single or multiple operator stations. Single transmitter multi-operator stations will be recognized as a distinct category from multi-transmitter, multi-operator stations. Two transmitters on the band at the same time is prohibited. Single operator stations may enter in either the all band, high band, or low band categories. High band is 20, 15 and 10 meters, while low band is 160, 80 and 40 meters. Operating on a band not allowed in your class is permitted but those points will not be counted toward your total score. Crossband and crossmode contacts are not allowed.

EXCHANGE:
W/VE stations will send RS(T) and state or province. All others send RS(T) and power. KH6 and KL7 are considered DX.

SCORING:
Score 3 points for each completed QSO. Each station may be worked once on each band on each mode for contact and multiplier credit. Final score is the total number of QSO points times the total number of countries on each band (for W/VE stations), or the total number of continental states plus VE/VO licensing areas worked on each band (for DX).

AWARDS:
A plaque will be awarded to the highest single operator DX phone and CW station (non-W/VE) in each continent. On both phone and CW, a certificate will be awarded to the highest scoring station in each category and classification in KL7, KH6, each ARRL section, and each country where a valid entry is received. Also, a certificate will be awarded to each non-country winner DX entrant making 1000 or more QSOs on either mode. ARRL-affiliated clubs may also participate in club competition as described in *QST.*

LOGS:
A summary sheet, log sheets, and DX check-off sheet for each band used is required from all W/VE entries. DX entries must submit log sheets and a summary sheet. Separate logs, summaries, and check sheets are required for each mode used from all entries (no check sheets for DX). Logs and forms are available from ARRL, 225 Main St., Newington CT 06111. Send completed forms and logs to ARRL at the address above no later than April 1976.

QCWA QSO PARTY

Starts: 2300 GMT Friday, February 13, 1976
Ends: 2300 GMT Sunday, February 15, 1976

Every contact with another QCWA member will count. Briefly the rules are as follows; check the *QCWA Newsletter* for any last minute changes.

EXCHANGE:
QSO Number, QCWA Chapter Name, and operator's name. Send "none" in place of chapter if not affiliated with a chapter. Holders of Golden 50 Year Certificates should add the suffix "D" after their QSO Number.

SCORING:
Contacts between members living in their own or adjacent countries count one point. Contacts between members living in nearby countries that are separated by an intervening ocean or country count as two points. Contacts between members living on different continents count as 5 points. Contacts between any member and a member with a 50 Year Golden Certificate count for one additional point. A contact with the QCWA memorial station W2MM/4 counts for 2 points. Stations may be worked both on CW and phone but only once on each regardless of band. Multiplier: Each different chapter represented in your contacts counts as a multiplier. Final score is obtained by multiplying the total number of QSO points by the total multiplier.

FREQUENCIES:
Phone: 1805-1825, 3940-3960, 7240-7260, 14240-14260 28640-28660, 14280-14300
CW: 1805-1825, 3540-3560, 7040-7060, 14040-14060 21040-21060, 28040-28060
Contacts made on frequencies outside the listed bands or on QCWA or other net frequencies are not valid and will not count in your total. You may answer on any frequency in the listed bands, but you should not stay on any frequency except that whose last digit is your call area (Example: W7/K7 would call CQ on 20 meters on 14247 or 14257 if on phone or 14047 or 14057 on CW.) This restriction does not apply to stations outside the 48 states.

AWARDS:
This year QCWA will award certificates to chapters with the three highest aggregate scores. At least three entries must be received from the chapter. The "Annual Operating Award" plaque will be presented to the highest scorer in the contest. Presentation of the award will be made in June, 1976. Scores will be printed in the June 1976 issue of the *QCWA Newsletter.* If you contact W2MM/4, include a QSL card of your own to receive a special memorial card from QCWA Headquarters.

LOGS:
A sample log may be obtained from Dave Davis by sending an SASE to him at: 6971 Grand Vista Way, South, St. Petersburg FL 33707. Identify each sheet of your log with your name, call, address, city, state and zip. Number pages serially and staple them together. List your chapter name and Golden Certificate Number, if you have one. Logs should show: time (GMT), freq, call, QSO nr. sent, QSO nr. received, his chapter, operator's name, mode, QSO points, and multiplier points – for each QSO. Compute your own score and include it with your logs. Logs should be mailed not later than February 15, 1976 to Dave Davis W4GQ at the above address. In case of controversy, the judges' interpretation of the rules and their decision is final.

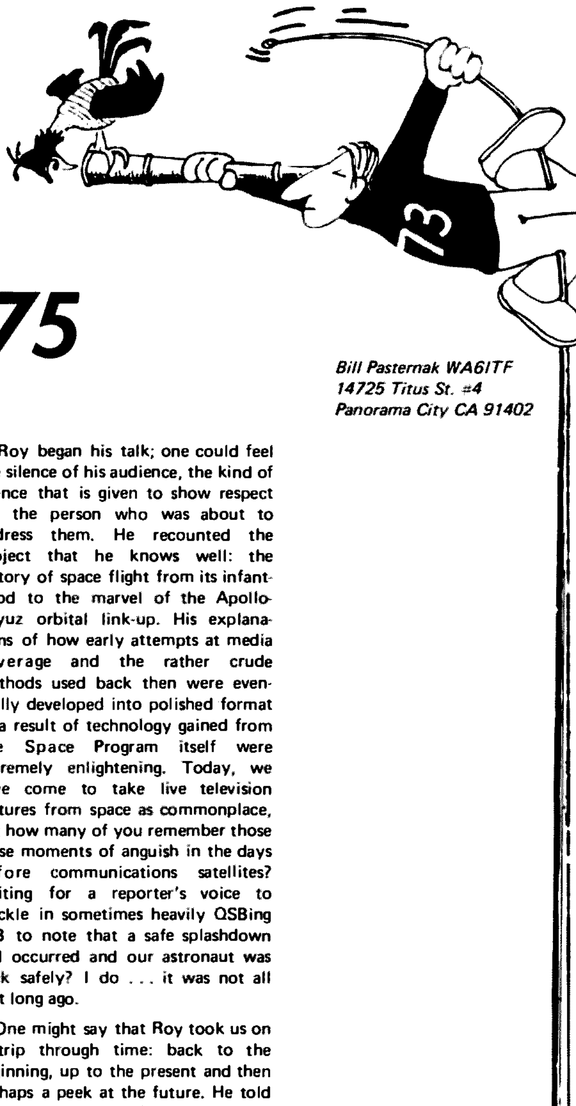
Looking West:



Ventura '75

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

The traffic on 101 heading north seems quite light for this hour on a Saturday evening . . . for long stretches it seems that this Torino is the only vehicle on the road . . . another vehicle passes and that sets me to wondering out loud . . . here I sit at 55 . . . the maximum limit that one can legally travel without the CBers' pal "Smokey" doing his number on you, and on a major freeway with this little traffic on it . . . well, a speeder just stands out like a sore thumb. Anyone who risks the wrath of the CHP (California Highway Patrol) to save a couple of minutes while enroute from point "A" to point "B", and risks not only his life but that of everyone else on the highway, has got to be a "bad guy" in my book. Besides, the evening is so clear that to speed would only take a lot away from the excitement of the events to come later this evening . . . relax, if you are a few minutes late for the evening's festivities . . . so what? . . . WR6ABE, Burt's repeater on Mt. Wilson, breaks squelch on the Motorola as I start up a rise . . . damn thing has ears that seem to hear everywhere and a voice to match . . . well, here's my chance . . . better give Bill a call and confirm things . . . "KH6IAF/6 Ventura from WA6ITF mobile 6 . . . are you there Bill?" . . . "WA6ITF mobile 6 from KH6IAF/6 . . . what's your ETA, Bill?" . . . "About half way there and expect to be about 10 or 15 late . . . go." . . . "OK . . . call me on .52 when you reach the California Avenue off-ramp. The hotel is just across the highway . . . go." . . . "Call you on .52 in about 25 minutes . . . 73s for now. KH6IAF/6 Ventura from WA6ITF mobile 6 on highway 101 clear WR6ABE" . . .

That, friends, is the way the weekend began. While most people attending this year's ARRL Southwestern Division Convention had made their plans weeks earlier, I had not been sure until about three that afternoon as to whether I would or would not make it. Already, I had missed the first 1½ days of the get-together due to business commitments, but the lure of an event such as this is just too much for yours truly to resist. Besides, I had to be there by noon Sunday to cover the SCRA meeting for this column. Mainly, I did not want to miss the banquet this evening. No, not for the food, though a good dinner was promised; it was the keynote speaker at the banquet that I wanted to hear.

There are very few people that I truly admire, people who have developed within their chosen field of endeavor to a point of true overall professionalism, to a point where society recognizes them as being the best in their business. The man that was to speak this evening was one of those few and, as someone involved in the same profession, though on a far more limited scale, this was one time that I intended to be there. Hence the rush to leave work at 6 pm and be at the Holiday Inn in Ventura by 8.

From the very beginning of the United States space program, the broadcast media have always given coverage of the events top priority. From the first experimental Vanguard flights of the late 50s and early 60s, to Alan Shepard's first manned flight, to our first moon landing, to last summer's Apollo-Soyuz joint U.S.-Soviet venture, we had but to turn on the one-eyed monster to "be part" of it.

Covering events of this magnitude takes the skill and talent of many people, and I suspect that one could sit and compile lists that might well be longer than an edition of this magazine. Technicians, engineers, reporters, editors: Specialists in every aspect of news dissemination, working with a combined effort to bring the story to you at the moment it happens. Professionals in the true sense of the word, and among these one name has always been a part. One person has always been a part of space flight news coverage as far back as I can remember: Roy Neal of NBC News. To most Americans he has been one of the knowledgeable voices that has guided them through the intricacies of space flight — both manned and unmanned. To us, the members of the amateur radio community, he is more than that, for he is one of us; he is Roy K6DUE, an amateur radio operator in which our entire community takes pride.

Roy began his talk; one could feel the silence of his audience, the kind of silence that is given to show respect for the person who was about to address them. He recounted the subject that he knows well: the history of space flight from its infanthood to the marvel of the Apollo-Soyuz orbital link-up. His explanations of how early attempts at media coverage and the rather crude methods used back then were eventually developed into polished format as a result of technology gained from the Space Program itself were extremely enlightening. Today, we have come to take live television pictures from space as commonplace, but how many of you remember those tense moments of anguish in the days before communications satellites? Waiting for a reporter's voice to crackle in sometimes heavily QSBing SSB to note that a safe splashdown had occurred and our astronaut was back safely? I do . . . it was not all that long ago.

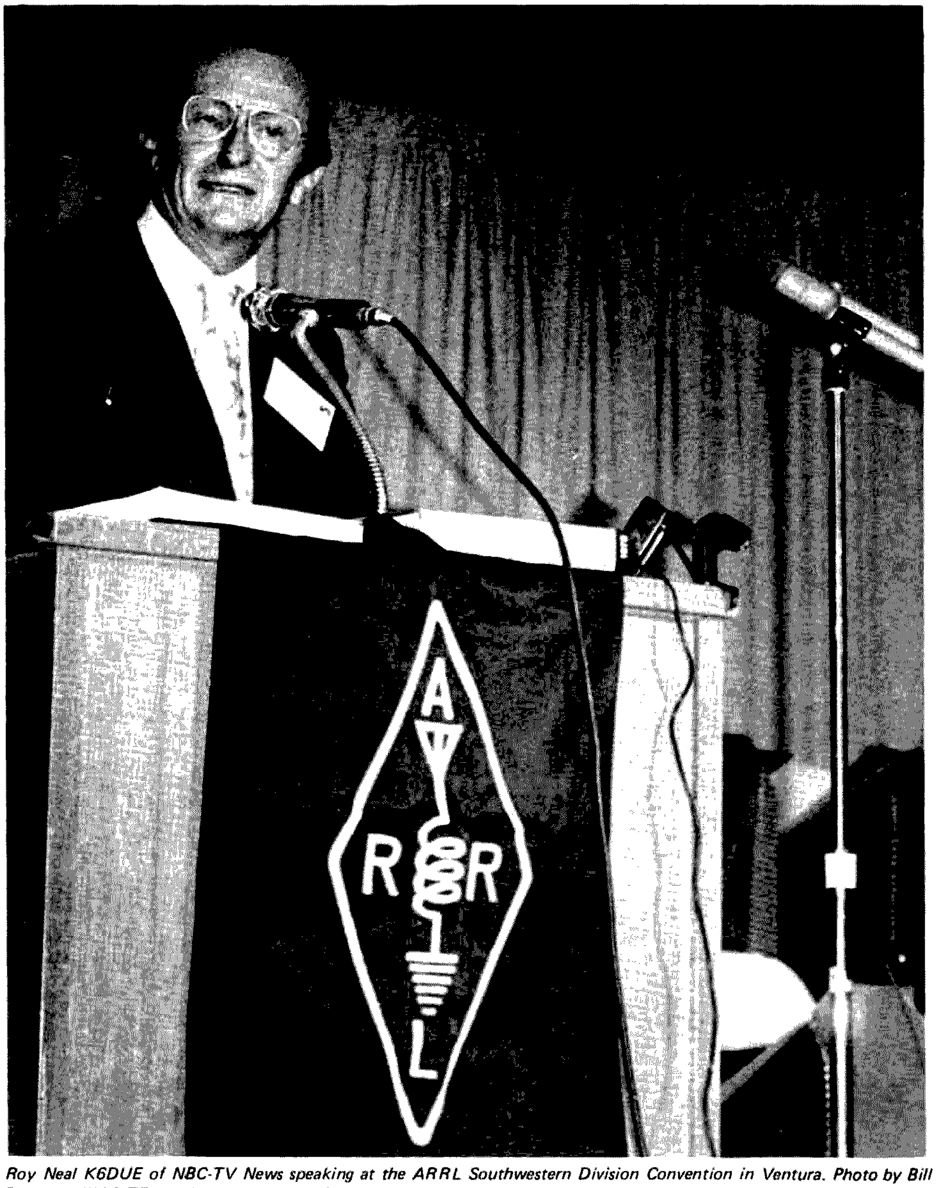
One might say that Roy took us on a trip through time: back to the beginning, up to the present and then perhaps a peek at the future. He told us how the knowledge gained as an amateur radio operator has aided him in the past and continues to aid him in developing the communication links necessary to cover these events. You could feel the pride that this man has in being a member of the amateur radio community. Throughout his talk he subtly tied his profession as a broadcast journalist to his love of amateur radio in a way such that you could almost feel that the two were inseparable — yet at the same time totally independent entities.

I suspect that it was his closing remarks which caught the imagination of every amateur present, especially those of us who are VHF-oriented. The space shuttle will be the next step in the story of man's conquest of space and eventually, maybe even in our own lifetime, men may live on the moon or other celestial bodies. To paraphrase Roy, eventually there may be amateurs on the moon and perhaps even repeaters up there . . . the pictures that formed in my mind were unreal. Imagine working the world on

VHF or UHF with but one squelch tail . . . imagine the thrill of the day when there will be an amateur repeater on the moon . . . the thoughts just blew my mind completely. When he finished, there came an ovation befitting the speaker and the words spoken.

As I sit here writing this some two weeks later, I cannot help but think that I was witness to something special. I have done much soul searching trying to find a reason for this feeling, but alas, I can only guess at it. Maybe it's due to my desire to emulate people like Roy and his colleagues (though on a far smaller scale) here in this column – a feat that I doubt I will ever achieve. To take on a responsibility such as Looking West or any other form of news reporting endeavor as an ongoing project is no easy task. There has got to be a love of what you are doing and a sense of responsibility to make sure you strive to do your best. In the many times I have watched Roy on the "tube" doing his job, I have gotten just this feeling – that of the true professional doing the kind of work he loves, the kind of work that is a part of him. Anyhow, for about 40 minutes on the evening of October 25, 1975, in the city of Ventura, California, there was a special kind of magic, a magic I will always remember.

Next month we will tell you a bit more about the Convention itself, but for now it's time to get on with some of the FM news – and that means the SCRA meeting held in conjunction with the Convention on Sunday, October 26th. If I were to choose one word to describe the major accomplishment of this particular meeting, it would be "Reunification." As reported last month, we were awaiting the outcome of "Concord '75," a meeting that would decide if there would or would not be a statewide coordinating council and, if there was, exactly what form it would take. Unfortunately, my deadline was about a week prior to the aforementioned meeting, so we can only now report that there will indeed be a CARC, basically along the formative lines outlined in earlier columns. The newly reorganized CARC got a real "shot in the arm" with the decision of the SCRA general membership to have the SCRA formally affiliate with CARC as southern region 144 MHz and 220 MHz liaison. (I use the word "liaison" for lack of a more descriptive word.)



Roy Neal K6DUE of NBC-TV News speaking at the ARRL Southwestern Division Convention in Ventura. Photo by Bill Pasternak WA6ITF; special processing by George Roberts.

The SCRA will still retain its own authority within its administrative area, and will continue operations as it has in the past. Its move to affiliate is one of support of the concept of a statewide organization overseeing problems of a statewide or national nature. It remains now to see if the Northern California repeater and remote owners, i.e., the recently established NARC organization, will also affiliate.

As it was explained by Gary Wood WA6DTX of the CARC, great care has been taken to structure the "new" CARC to prevent any sort of unilateral power structure from developing. The directorship will consist of representatives from each of the four (yes, I know that past columns had said three, but at Concord it was decided that there would be four regional bodies) regional coordinating bodies. Each regional body will appoint three people to act as area representatives to the CARC Executive board and any one member of this board will have veto power over the actions of the entire board. The remaining three board members will be the officials of the CARC itself, and this body *will not* involve itself in matters of local coordination policy or with local standards and practices. The main purpose of the "new" CARC is to provide the California FM community with a totally unified front in dealing with other areas and other organizations such as the FCC, the ARRL, etc. The vote to affiliate was unanimous and, along with SCRA's current chairman Dick Flanagan, Bob Thornberg WB6JPI and Dick McKay K6VGP were elected as SCRA representatives. (As SCRA Chairman, Dick Flanagan's appointment was automatic.)

I suspect that Gary summed up the goals of the "new" CARC best in his opening remarks. To paraphrase what he said, at one time about ten years ago we were all one FM community, but over the years we have permitted ourselves to drift apart and become individual interest groups (such as repeater and remote). The aim of the reorganized CARC is to bring all special interests together once more under one roof for the continued well-being of amateur radio. The first general membership meeting of CARC will be held here in the southland next spring, and at that time I hope to be able to report on some "good things" coming from CARC.

Talking about official recognition, the amateur radio community really got some of the best yet. About a year ago, a group of local amateurs banded together and formed the Community Amateur Radio Service, an organization that has worked along with the Los Angeles Police Department in an effort to help thwart the spread of crime. These amateurs have devoted their spare time in public service toward their community and their success has been such that the LAPD has seen fit to issue the following letter to the CARS people:

William Orienstein
President C.A.R.S.
C/O N.B.C. T.V.
3000 W. Alameda
Burbank, California

Dear Mr. Orienstein

Citizen involvement with local police is of paramount importance in any crime prevention program. During the last year your organization has been instrumental in combating rising crime patterns within our area. Please convey our commendation to your entire organization. Your help has undoubtedly reduced crime in areas of deployment and saved our taxpayers in time and money.

If my office can be of any assistance during subsequent deployment please contact me.

(s) L. Binkley, Lieutenant II
North Hollywood Area
Community Relations Officer

Talk about good public relations! In my book the foregoing is super good "PR" for the amateur radio community: Amateurs working hand in hand with the police to make a safer community for you and me to live in. We need more groups like this all over the nation, since the concept of public service is one of the basic precepts of amateur radio itself.

CONTESTS

from page 8

TEN-TEN NET
WINTER QSO PARTY
Starts: 0001 GMT Saturday, February 14, 1976
Ends: 2400 GMT Sunday, February 15, 1976

The contest is sponsored by the Ten-Ten International Net of Southern California, Inc., and is open to all amateurs — but only 10-10 members are eligible for awards. All contacts must be made on 10 meters, any mode, and a station may be counted only once.

EXCHANGE:
Name, QTH and 10-10 number.

SCORING:
1 point for each contact; 1 point if with a 10-10 member; 1 point if outside your own state, province or country. Maximum of 3 points for any one contact.

LOGS:
Logs should include date and time of each contact as well as the required exchange information.

AWARDS (for 10-10 members only):
Certificates to first and second place winners in each US district, Alaska, Hawaii; each VE district; Central America and Caribbean; South America; Europe; Africa and South Atlantic; Asia and Northern Pacific; Australia, New Zealand and South Pacific. Send logs to Grace Dunlap K5MRU, Box 445, La Feria TX 78559, by April 1, 1976. For complete results, see the *10-10 Net Summer Bulletin.* To become a 10-10 member, work any 10 members and send a list of those contacted along with $3.00 to the manager in your district.

RESULTS OF THE 1975 QRP — SUMMER — CONTEST

QRP Section (first 10 places of 54 entries)

	Call	*Points*	*Bands*	*Input Power*
1.	WB9LGZ/9	12908	40	3 Watts
2.	GW4DOO	10976	40-15	9 & 5
3.	G3IGU	8088	160-15	3 & 8
4.	G3DNF	7688	80-15	3 & 8
5.	HB9QA	6250	160-20	8 & 3
6.	DJ7MG	6187	80-20	7
7.	DL6ZG/P	5662	80-20	2
8.	DJ3WM	5439	80,20,15	5
9.	GW3PG/P	5372	160-20	2 & 3
10.	G3NEO	4986	80-10	2

Best Band Results

Band	*Call*	*Score*
160	DJ1ZB	180
80	DJ9IE	2680
40	WB9LGZ/9	12908
20	OK1MGW/P	1485
15	G3DNF	1040
10	DK5AQA, DK7OJA	78

First place in the QRO section (of three entries): DM2FIL/P, with 48 points.

RESULTS

SOCIAL EVENTS

MANSFIELD OH
FEB 8

The Mansfield Mid-Winter Hamfest/Auction is now a new day and location. It will be held on Sunday, February 8, 1976, at the Richland County Fairgrounds. Forums, large indoor flea market area, displays, door prizes and auction; easy access from I71 and US 30. Registration $1.50 in advance, $2.00 at the door. Tables for flea market $1.00 each. Doors open at 9 am; auction begins at 2:00. No commission charged. Talk-in 3,972.5 kHz 146.52 and 146.34/94 MHz. Additional info and advanced tickets from Harry Frietchen, Jr., K8JPF, 120 Homewood Rd., Mansfield OH 44906. (419) 529-2801 home; (419) 524-1441 work.

WHEATON IL
FEB 8

The Wheaton Community Radio Amateurs annual midwinter hamfest is Sunday, February 8, at the DuPage County Fairgrounds, Wheaton, Illinois (Manchester Road, near County Farm Road), 8 am to 5 pm. Tickets $1.50 advance, $2.00 at the door. For advance tickets send $1.50 each and a self-addressed stamped envelope to L. O. Shaw W9OKI, 433 S. Villa Avenue, Villa Park, Illinois 60181. Advance tickets postmarked no later than February 1.

TRAVERSE CITY MI
FEB 14

The Cherryland Amateur Radio Club will hold its third annual Swap 'n Shop on Saturday, February 14, 1976 from 9 am to 4 pm at the Northwestern Michigan College campus in Traverse City. Talk-in 146.52 and 3935. Door prizes will be given away. For more information contact Bill Mader WA8WWM, Box 2, Empire A.F.S., MI 49630. Donation is $1.00.

CUYAHOGA FALLS OH
FEB 27

The 1976 Cuyahoga Falls Amateur Radio Club Annual Auction and Flea Market will be held on February 27, 1976 at the Bolich Jr. High School, Cuyahoga Falls, Ohio. Admission $1.50 advanced registration. Deadline February 1, 1976. $2.00 night of auction. Talk-in frequency: 84/24-04/64-52/52. Call: W8VPV. Advance tickets: K8VAK and XYL, 3043 De Walt Dr., Akron OH 44312, 216-644-1213.

ROCK FALLS IL
MAR 7

The Sterling Rock Falls Amateur Radio Society Hamfest will be held March 7, 1976 at Sterling High School Field House (bigger and better location), 1608 - 4th Avenue, Sterling IL 61081. Tickets $1.50 advance – $2.00 at door. For info write – Don VanSant WA9PBS, 1104 - 5th Avenue, Rock Falls IL 61071. Talk-in 94 simplex.

VERO BEACH FL
MAR 20-21

The Bi-Centennial Treasure Coast Hamfest will be held at the Vero Beach Community Center Saturday and Sunday, March 20 and 21, 1976. Sponsored by Vero Beach Amateur Radio Club, Inc., and St. Lucie Repeater Association, P.O. Box 3088, Vero Beach FL 32960.

WASHINGTON DC
MAR 24

1976 ARRL Technical Symposium on Mobile Communications will be held on the evening of Wednesday, March 24, 1976 at the Statler Hilton Hotel, Washington, DC. Areas of interest are: HF/VHF/UHF mobile communications, repeater technology and operations, signaling and control techniques, special mobile communications (AMSAT, ATV, RTTY, etc.); especially subjects of interest to both amateur and commercial mobile radio users. Summaries are due by February 1, 1976. Manuscripts, photo of author and biographical sketch of amateur/electronic background due by March 1, 1976. Write: Paul Rinaldo K4YKB, 1524 Springvale Ave., McLean VA 22101 or call (703) 356-8918 evenings.

ST. CLAIR SHORES MI
APR 4

The South Eastern Michigan Amateur Radio Association is holding its Eighteenth Annual SEMARA Swap 'N' Shop on April 4, 1976, from 8 am EST to 3 pm EST. It will be held at the South Lake High School in St. Clair Shores, Michigan, on the Southwest corner of Nine Mile Road and Mack Avenue.

MEADVILLE PA
MAY 1

The Northwestern Pennsylvania Swapfest will be held May 1, 1976 at the Crawford County Fairgrounds, Meadville PA. Free admission. $1 to display. Flea market begins at 10 am. Hourly door prizes and refreshments. Commercial displays welcome. Indoor if rain. Talk-in 146.04/64 and 146.52 MHz. Details: Crawford Amateur Radio Society, Box 653, Meadville PA 16335.

JAFFREY NH
MAY 15

The 1st Annual Fly In and Flea Market will be held Saturday, May 15, 1976 at the Jaffrey Municipal Airport (Silver Ranch) in Jaffrey, New Hampshire. *73 Magazine* will host the event. Picnic facilities, food stand, great ice cream, horseback riding available at Silver Ranch stables across the road from the airport (200 yds). Plenty of hangar space for exhibitors, etc. Come one – come all – if you can't fly – drive – but get here. Jaffrey is 6 miles south of Peterborough on U.S. Rt 202.

HAM HELP

I am a subscriber to *73 Mag.* I think it is a very fine magazine. This note is written to thank *73 Magazine* for publishing Ham Help, as appears on page 6, Nov/Dec, 1975:

I wrote to Fred Kahn WB2TBC for ham help and within one week received an informative reply. The information will be of great value to me. Thanks to all the fine people at *73 Mag.*

Edward Victor WN8SEG
Lake Milton OH

World Radio News, a newspaper published for hams, 2509 Donner Way, Sacramento CA 95818, has offered to supply amateur radio clubs with the names and addresses of all amateurs in their respective areas who are newly licensed or upgraded. Our club has used this service since June 1975 and has received over 200 names so far.

We send each one a copy of our newsletter and an invitation to visit our next meeting. Over 10% have joined our club and more are coming each month. We give others the name of a club closer to their homes. A great service – use it.

Bob Reiley WB2FHN

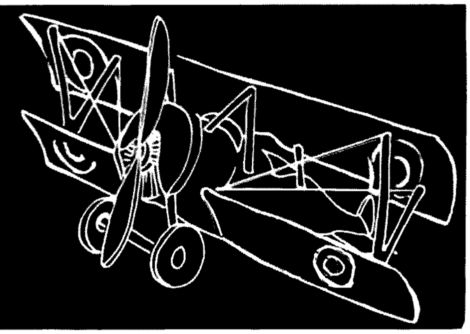
Autobiography of an Ancient Aviator

W. Sanger Green
1379 E. 15 Street
Brooklyn NY 11230



To transport General MacArthur I had the real shaky ship pulled out of the back of the hangar and dusted off.

Langley Field Incidents - 1925

Along toward the end of October, one of my men told me that his mother was in serious condition in a Boston hospital and asked me for a few days furlough to visit her. I gave him the furlough and, in addition, I got Major Westover to authorize a flight to Boston for him. We started out early the next morning in a DH and got as far as Cape May, N.J., when we were forced down by weather. Next morning we got an early start, stopped at Lakehurst for weather information, fueled at Mitchel Field, and got to Boston by early afternoon. While my passenger was visiting his mother I tested a Moraine Parasol that a group had assembled but hadn't been able to find anyone to flight test. After inspecting it I offered to take it off and fly it around for a few minutes for $25 and another $25 if I landed it safely. I got my $50. I stayed the night with the Hal Bazleys. (I had delivered an LWF plane to him in 1923.) On the way back the next day I ran into treetop weather between Bolling and Langley. I decided that before the trees got any taller I had better sit down in the first field that came along. I landed in a muddy farm field near Mimini Grove, Va. The farm was run by four bachelor brothers. They had no phone, so I got them to hitch up a horse to a wagon and drive me to the nearest phone, which was in a small store three miles away. Then I checked in with Langley operations so they wouldn't start a search for us. While at the store I bought 10 lbs. of flour, 10 lbs. of sugar, 10 lbs. of salt and a gallon of molasses to take back to the farm. This was real back country. The farm was pretty much self-sustaining, so they were glad to get the staples I brought in exchange for dinner, bed and breakfast. They had no watch or clock on the place – lived by the sun. No electricity or running water (a pump over a well in the yard), but they did have a three hole back house. By noon the next day the field had dried out a bit, so I managed to lift off and get back to Langley that afternoon.

Sometime in September a young recruit was assigned to my squadron. I had a talk with him when he first reported: a nice kid just out of high school in the Pennsylvania Dutch country. He was assigned to one of the maintenance crews in the hangar. About the middle of November several bombers on the line were idling their engines preparatory to a formation takeoff when, for some reason, this recruit, who had been told to remove one of the wheel chocks, came from under the wing and walked right into an idling propeller. We sent a corporal and a flag home with him.

On the 30th of November my turn came to fly what they called the "Model Airway." This was a weekly scheduled DH trip that took 5 days, with stops at 16 Air Service fields from Detroit to St. Louis, and averaged about 25 flying hours. Anyway I was away on this trip when two of my lieutenants paid off the squadron for November. Among those they paid was the deceased recruit. The error wasn't discovered until a couple of months after all three of our tours of active duty had ended. The two lieutenants and I had correspondence with the Army on the subject for the next five years.

Sometime in September I got orders to provide a bomber and crew to transport General MacArthur to Bolling Field, D.C. I got the word that he was going to either testify at or be on the court of the Billy Mitchell trial in Washington. The message was clear so I had the real shaky ship pulled out of the back of the hangar and dusted off. I tested the engines, made a short test hop to make sure it would hang together, then set her out on the line to await the General's arrival. Oh! I forgot. I had my electrician rig a wire to the right engine ignition switch from a button on the side of my seat. When the button was pressed, the right engine would cut out. When MacArthur arrived, we fitted him out with helmet and goggles and loaded him into the copilot seat – and away we went. I pointed out the empennage (tail) that was fishtailing its way behind us and told him that, after all, we couldn't expect these WW I stick and wire planes that were engineered and built 8 to 10 years ago to last forever. I also told him that I thought we were just lucky that there was no war going on where we had to use the types of aircraft we had for any military missions etc., etc. In the meantime, that right engine kept misbehaving. I managed to keep our average ground speed down to about 50 mph on the trip. Upon our return to Langley that afternoon Old Wobbly was put in the back of the hangar again.

One day I was checking Bill Winston (an old friend from Carlstrom Field) out in a bomber. He was an excellent pilot but he had never flown a two engine plane. In about twenty minutes his air work was OK so I told him to try a landing. Before I go any further let me explain that in those days flying fields were all grass – no runways. So, to get on with the story, Winston was making a good landing approach into the wind when I saw a DH coming in for a landing downwind – and headed right for us. We were leveling off when I decided that the fellow in the DH hadn't seen us, so I poured on full power and told Winston to pull up right. We missed the DH so Winston took the ship around and landed it OK. We missed a collision by about 30 feet. This was not an enjoyable experience, so I went right to the field operations office to enter a complaint. While I was talking it over with the operations officer, who should walk in but Major Westover, the field Commandant. He was the pilot of the DH and was all shaken up. He took the entire blame for the incident and begged pardon, etc. I told him that we were all lucky and should be glad that we hadn't made the boys in the hospital heat up that big pot of wax.

Three or four nights a month we had to do a tow target mission for the anti-aircraft and searchlight batteries at Fortress Monroe. This was a bomber job. The target was about 25' x 10' and was made of canvas with weights to keep it flying as near horizontal as possible. A tow cord with release was attached to the tail of the bomber and then laid on the ground parallel to the takeoff run for about 1200 feet to the tow target. When you took off after dark you would pick up the target and climb as fast as possible and proceed to the Chesapeake side of Fortress Monroe at about 1500 feet. The searchlights would try to find the target and pass it on from one to the next. Then the anti-aircraft battery would shoot at (hopefully) the target. We would make passes over the battery for about an hour, each time coming over at a different altitude and from a different direction. Then we would go back to Langley, release the cord and target and land. It was sort of fun except that sometimes the anti-aircraft shells would come too close for comfort.

Next month I'll wind up my Langley Field tour of active duty with a couple of incidents and jump into the hotel and restaurant range business for awhile.

NEW PRODUCTS

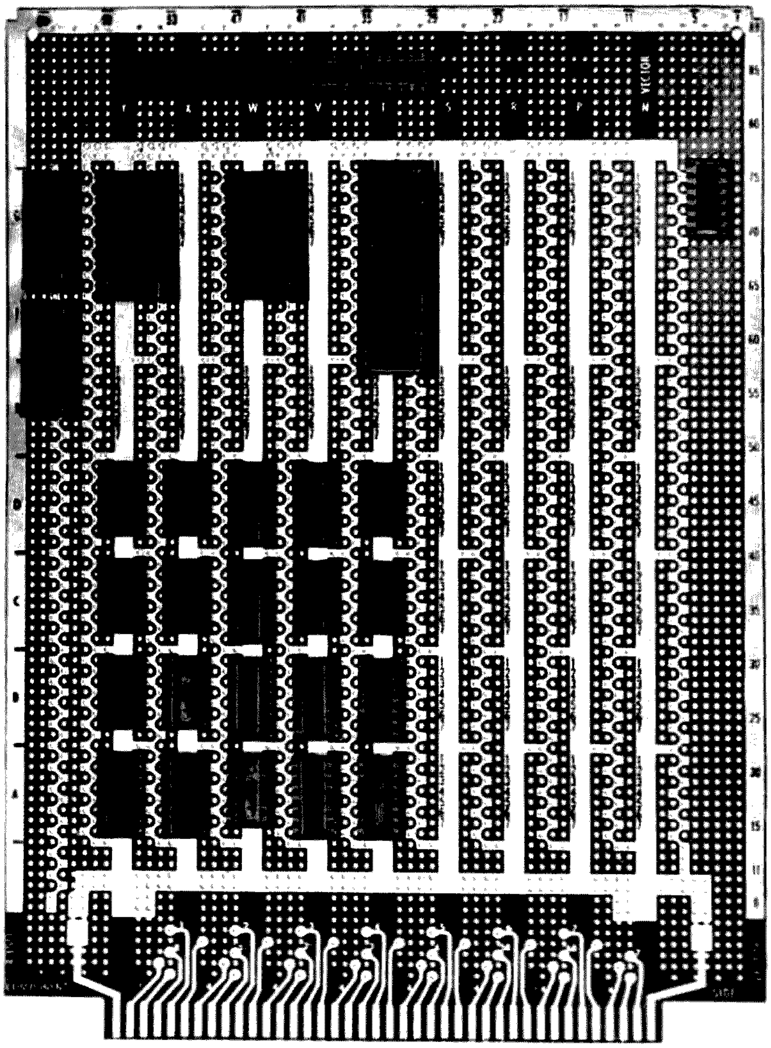
MICROPROCESSOR/INTERFACE BOARD OFFERS MULTI-LEVEL BUSING

A new Plugbord, from Vector Electronic Company, accommodates up to two supply voltage levels to permit the use of a wide variety of microprocessor and interface circuits. Designated Model 4350, the board has copper cladding on opposite sides for shielding and to supply primary power (plus on one side, negative on the other). Interwoven zig-zag lines, also on opposite sides, facilitate power distribution. The combination allows convenient use of both MOS and TTL devices.

Primary power buses, which pass under the DIP positions, are unperforated and opposite one another. This provides bypass capacitance for transient suppression. The zig-zag lines are also opposite but with the zigs and zags out-of-phase. There is ample space and mounting means on the board for bypass capacitors at each DIP position and also at the incoming power position.

The large 7 in. by 9.6 in. board will hold 63 fourteen or sixteen-pin DIPs. Alternately, five 24-pin microprocessors and 45 DIPs may be placed in the main field. Either socket blocks or individual socket pins may be mounted to order, or the board will mount 40-pin microprocessor (0.6 in. tab spacing) units. Plugbords may be purchased bare as Model 4350. Additional DIPs may be placed in the side margins or in a large unclad area at the top of the board. For input/output, the board has 40/80 etched contacts spaced on 0.125 in. centers. Unclad areas may also be used for DIP I/O connectors. Alternatively, tape cable connectors may be attached at the top or side of the board.

The DIP board, originally developed for interface with Texas Instruments' 980 Series computers, has a multitude of general applications. Due to the abundance of extra 0.041 in. dia. holes on tenth-tenth grid, the board may also be used for



Vector Plugbord Model 4350 (shown with added DIPs) accommodates 14-, 16-, 24- and 40-pin DIPs for use in a variety of circuit applications.

analog circuitry, mounting resistors and most other components easily. Either the Vector P173 Wiring Pencil technique (with solder) or wrapped connections may be used.

On the left side of the board the letters "A" through "I" mark each double nine-hole zone. Along the bottom the letters "0" through "Y" designate vertical zones. Like a road map, specific components may be called out by the coordinates. DIP pin numbers from 1 to 7 are etched into the clad area. General X-Y coordinate numerals are shown at top and bottom.

The Plugbords are made of flame retardant glass material and have all surfaces tinned except the contacts which are nickel-gold. Holes for ejectors are supplied for easy card removal.

The boards are priced at $14.95 each in 1-19 quantity, with quantity discounts available. They are in stock at Vector Electronic Company and may also be ordered through the firm's AVID distributors in the United States and Canada.

Vector is a major manufacturer of sockets, terminals, connectors, printed circuit boards, card cases, enclosures and complete packaging systems.

Vector Electronic Company, Inc., 12460 Gladstone Avenue, Sylmar CA 91342. Phone: (213)-365-9661; TWX: (910)-496-1539.

NEW MILLEN CATALOG

Remember when you could walk into a distributor and buy such goodies as coil forms, switches, mechanical drives, high voltage connectors and the like? They are still available factory direct, along with other goodies, from Millen. Send for their new catalog. *James Millen Mfg. Co., 150 Exchange St., Malden MA 02148.*

3 NEW HUFCO UNITS

Hufco – the makers of the popular 3 digit Communications Counter, TWS-3, designed specifically to read-out transmitted frequency – announces two new frequency counters and a prescaler. The two counters have 300 mV sensitivity and operate through 250 MHz. They are called the model TWS-300 and TWS-600 for three digits and six digits respectively. Both the three and six digit units outwardly look identical to their 30 MHz counterparts (no pun intended). Both come equipped with 115 V ac power supplies, but will work with 12 V dc through a 1 Watt dropping resistor. The most amazing thing about the counters is their price: The TWS-300 is $99.95 kit ($117.95 assembled) and the TWS-600 is only $119.95 kit ($139.95 assembled). Currently the units are available only from the factory, but dealer inquiries are invited (must be on letterhead).

Hufco's low cost prescaler works with any counter, and will multiply the capability of the counter by 10 up to 250 MHz. It comes assembled, with its own power supply on a single PC board suitable for inserting inside the case of your present counter. The low price is $59.95. Low frequency limit is approximately 1 MHz.

D-D's MAGNIFIER/LAMP

If you've been doing any IC construction projects or kit building, you are well aware that one of your most important needs is some way to see what you are doing. Enter the D-D Enterprises combination magnifying glass and fluorescent lamp which clamps on your workbench – or even a card table, if you are more the instant workshop type of builder.

The fact is that you need a lot of light and a lot of magnification to make sure that all those holes are soldered right on PC boards and that there are no bridges between islands or plug-in contacts. With the D-D you can work with both hands free and see exactly what you are doing.

Permission is granted to cut out this little piece and leave it for the XYL as a hint for a present. Look for the ads or write to D-D, Box 7776, San Francisco CA 94119. Costs less than $50. Be sure to see the ad in this issue.

EDITORIAL BY WAYNE GREEN

from page 3

Inputs are things like teletype machines, television typewriters, ASCII output keyboards, cassette tapes, paper tape . . . things like that. Outputs are mostly the same things. I/O. You'll like it.

I/O also represents the fundamental quantities of digital electronics, zero and one. Okay?

IS ANARCHY SO BAD?

While I've only been listening to the citizens band in New England and New York, what I've been hearing has been very encouraging. The fact is that the FCC policy of just leaving the CBers alone has worked out rather well. The CBers themselves have accommodated to the medium and many of the excesses of the past are that.

The sunspot minimum has helped the situation, of course. The ban on amplifiers has helped, too.

It's been ages since I've heard any bad language on CB . . . most of the contacts there are very friendly, ritualized and superficial . . . but they *are* radio contacts and it is a fact that millions of people are getting a taste of what radio can do . . . just a taste, mind you.

Whenever I hear an Amateur bad-mouthing CB I ask if he has used CB within the last year or so . . . the answer, without fail, is no. I haven't heard any CB users griping much about CB as it is today. I'm listening whenever I drive anywhere and find the road information of great value and many of the overheard contacts quite interesting. Most are not, naturally.

I may be wrong about all these people who are getting their feet wet for the first time in radio communications being prime material for conversion to Amateur Radio. I'll be most interested in hearing your luck with this . . . or lack of it.

Those CBers who are serious enough about the medium to get sideband gear seem to be particularly prime targets for Amateur Radio classes. It's something to think about.

The coming de-regulation of amateur radio may look a little less frightening to those who feel that stricter controls are needed rather than freedom if they spend some time operating on CB and seeing what a totally unregulated radio system is like and how amazingly well it works.

PC COPYRIGHT

Warning . . . if you are designing or manufacturing printed circuit boards you would do well to include a copyright notice on the board. More and more manufacturers are regretting this oversight as bogus boards turn up in their repair department . . . boards with their circuits on them, but obviously made by someone else . . . and poorly made.

Bill Godbout recently got a board in for repairs . . . he couldn't believe it, how could one of his boards be warped like that? A close inspection provided the answer: he'd been ripped off. I've seen rip-offs of Southwest Tech boards too, so there is a lot of that nonsense going on.

Warning . . . if you are going to buy a PC board, make sure you get it from the manufacturer if you are ever going to want help with repairs. The buck or two you save by greasing the palm of a rip-off artist may come to haunt you. Look for that copyright mark when you buy a board and watch out for flaky outfits . . . there are a lot of them.

FOREIGN LANGUAGE

My first brush with computer folk was when I decided to investigate the possibilities of an in-house computer for *73 Magazine*. I quickly found that the salesmen were unable to communicate with me. I turned to some ham-computer friends and found that they, too, spoke in computer language and were unable to interface with the English-speaking world.

What is it that happens to otherwise normal people when they learn to talk

in computerese? Seemingly they then forget what it was not to know this language and to be unable to further communicate with the non-computer world. Weird.

We need a lot of fundamental articles in *73* on microcomputers and their amateur radio applications, but we also need to have these written in either English or, worst case, ham language. One of these days someone is going to come along who has learned the computer field and still remembers that there was a time when he was not sure what software subroutines were ... and he is going to become rich and famous as an author. Well, famous, anyway.

73 SWEEPSTAKES WINNERS

As an experiment *73* ran a subscription sweepstakes contest last Fall with some attractive prizes. The idea was to create enough energy in subscribers to get them to send in renewal cards early and help us to save money by not having to send three and four notices.

The first prize was a windjammer cruise for two ... a ten day extravaganza of sailing, skin diving, swimming and possible DXpeditions among the rarer Caribbean islands.

The second prize was an Icom IC-230 with ac power supply ... and who couldn't use one of these ... or even two?

Third was a Chronex digital watch ... then a MITS 908M calculator, still one of the best of the breed and way above most of the hand calculators in useful functions.

Other prizes awarded were a cassette recorder, a digital clock for the shack, an ASCII output keyboard and many of the *73* books. In all there were 117 prizes awarded.

The windjammer cruise for two was won by P. G. Kaiper WA7UMF of Milwaukie, Oregon. Enjoy.

The IC-230 went to John Grubs W8GRT of Sylvania, Ohio. The Chronex digital watch was won by D. R. Krusza WB2IUD of Eggertsville, New York. The MITS calculator went to W6RDP in Canoga Park, California, the ASCII keyboard to C. P. Isbell K5EWC in Seguin, Texas, the cassette recorder went to Mickey Gallagher W6JRA of Colton, California and the digital clock for the shack to an L. Kushner of Burbank, California.

One of these days, when we get things organized again, we'll get another subscription renewal sweepstakes going ... hopefully on a regular basis. Right now things have been happening so fast that we are having a difficult time keeping up.

"GET OFF THIS NET FREQUENCY ..."

A nice front page article in the Columbia, South Carolina *The State* described how a local amateur (Henry Randall) helped save a Canadian boat headed from North Carolina to the Virgin Islands. The emergency call came in from VE0MCM/MM with three Canadians aboard and lost in a heavy storm for three and a half days and some 450 miles off course.

The call came while three locals were having a chat on 75 meters. Henry sat up with them all night and helped the Coast Guard find the lost boat and save the three men. All were suffering seriously from seasickness and were too weak to stand up. Two are, as of this report, still hospitalized and listed as in serious condition.

The medical advice passed along by Henry is credited with keeping the men alive until they were rescued. In all it was another of those amateur radio emergency situations to which all of us can point with pride.

Well, almost all. There was a chap in Florida who refused to give his call but who was very insistent that the emergency be moved down below 3900 kHz so he could conduct his net. This lid wouldn't shut up until someone took the time to explain to him in detail why *his* net frequency was being used for an emergency. I suppose we have to have one like that, right?

Thanks to WA4AIV for the report on the emergency and nice newspaper clippings of the amateur radio PR which resulted.

MOBILE NOISE

A nice article came in recently on mobile operating, but it had one striking omission ... there was nothing about how to get rid of the worst enemy of mobile contacts ... noise. Oh, there have been articles on this problem in the past, but car design is keeping up with and passing the old techniques.

The time was when you could easily isolate the spark coil and set about getting rid of ignition noise and things were cool. How many of you have looked into your engine compartment recently? I confidently raised the long hood of my Datsun 280Z ... hell, I've been at this for years, big deal there's noise in the FM rig ... and even worse noise on 10m ... as a matter of fact you wouldn't believe the 10m noise.

It didn't take me long to discover that something has happened to automobile design ... this car of mine is packed with cables going all over the place. I did find the coil, but I couldn't find the transistor oscillator which drives it ... and that seemed to be what was garbaging the 10m receiver. How could I get rid of the noise when I couldn't even find the main elements of the system? Oh, for wise guys who ask why I didn't get out the instruction book ... I did, have you looked at yours? Mine did not give any hint as to where any oscillator was located.

The dealer who sold me that car shook his head over the wild screeching noise coming out of the speaker. Seems he has a lot of customers with the same problem and he doesn't know anything to do about it. He did show me a big manual on the car and I managed to find the oscillator by tracking through the electrical system. The diagram was more complicated than most computer schematics.

Has anyone out there been able to quiet the cry of these newfangled transistor oscillators they're using to drive spark coils these days? I need to know and I'm sure a lot of others would like to know too. If I tell you something confidentially you'll not be angry and keep back the mod for quieting my monster, will you? I lied. That wasn't 10m where I had all that noise ... it was 11m.

INSTANT CODE?

Well, almost. The fact is that it is possible, using recently discovered techniques, to learn the code in a fraction of the time most of the old timers had to devote to it. It isn't yet completely painless, but a whole lot of the sting has been removed.

Funny, the modern system not only works, it makes sense, too! About the only thing wrong with it is that it flies in the face of about 50 years of teaching in the handbooks and license manuals.

Any old timer will tell you that to learn the code you have to start slow and then pick up speed as you learn. You *can* learn it that way ... if you're got lots of time and patience. That system has defeated an awful lot of prospective amateurs who didn't have the patience it took to do it that way.

Think about it for a moment. The whole idea is to train your mind to automatically recognize a sound pattern and have your hand write a letter. It's not much different from a lot of other patterns we teach ourselves ... tying shoes, driving ... playing an instrument. But what happens to the learning process if we keep changing the sound patterns we are trying to pattern into the mind? Morse code at five words per minute doesn't sound anything at all like eight or twelve words per minute. What we have been doing in the past is learning to copy at one speed, then another, and another ... driving ourselves unnecessarily crazy.

The modern system is to learn the sound of the characters at the speed you want to copy and just space the characters to give the mind time to work. Even at five words per minute each character should be sent at the desired 13-per. This will cut a hundred hour back-breaker into a ten hour jaunt.

Now, with over 25,000 of the *73* code tape cassettes using this system in use, and with most of the club-organized classes using the *73* code cassettes, few prospective amateurs are having to slave away with the old system ... thank heavens.

The whole cassette project came from my effort to find out which code teaching system was best so I could recommend it in the magazine. After reviewing everything I could find, I decided that none were what I considered up-to-date. I talked with a couple code tape people and asked if they had any plans to modernize ... no. So I said what the hell and sat down and made my own master tapes. It was a grueling experience turning out a solid hour of absolutely perfect

code without variation in speed. Try it sometime, you code freaks.

The cassettes now available start with an introductory one hour tape that teaches the 40 characters you need to know . . . letters, numbers and punctuations. Many people get them in an hour. For those going for Novice or Tech there is a six word per minute tape, one hour of gibberish, unmemorizable. Those made of sterner stuff can go right to the 14 word per minute tape. It's slow going at first, but then things fall into place and instead of copying at five, six, seven, eight, etc., you find you are copying at 14! And you also may notice that the old hump at ten words per minute just isn't there.

The hump was the painful result of finally being forced by the speed of the code to stop translating and, at long last, get started where you should have in the first place . . . automatic copying. Everything before the hump was wasted. Some people, with monumental effort, are able to translate code . . . listen to the character and then remember what it is . . . right up to almost twelve words per minute. At this time the speed of the brain won't hack it further. It's so much more difficult that it is a real pity when people get into that bind.

For speed demons I have a 25 wpm tape. Canadians may prefer the 10 wpm tape. Extra Class devotees will want the 21 wpm practice tape. I've never heard of anyone failing the FCC exam when they could copy this tape.

The major problem in copying code for the FCC is overcoming the panic of the test. By setting the speed on the tapes a bit high I've found that this margin is enough to bring on a giant sigh of relief when the code test starts . . . it sounds so slow compared to the tape that all fear disappears and the whole thing is a piece of cake. The FCC tests are in relatively plain language too, which gives you an extra margin since the tapes are in cypher to prevent memorization.

OSCAR CONTACT

After noting the low level signals of Oscar 7 in mode A and the beautiful signals in mode B, I could see which way I should go. But there were some serious technical problems between wanting to get on via Oscar and actually getting on the air. You don't yet go out and buy a 432 sideband rig to poke that signal into Oscar.

The downlink was not much of a problem. I got a KLM two meter circularly polarized beam for starters. Then came the Vanguard converter to be mounted up at the antenna. That should do it. About that time my Signal One gasped and emitted a very expensive smell. That was going to be my downlink receiver on 10m. Panic . . . eased by some promises by ITC (which was the manufacturer of the rig) to fix it. This later was changed to a deal whereby we would get a couple of their Multi-2000s in exchange . . . not quite as good as the converter into a hot 10m receiver, but usable. We're still waiting for the Multi's . . . or the Signal One . . . or *something!*

Tucker had an old Yaesu 560 in good shape so we bought that and put that into the line as a receiver. Oscar came in fine on this once the antenna was in place. That was half of the project . . . well, considering the complexity, that was 1/10th.

After a good deal of digging around I located an outfit in California which made 28-432 MHz tube type converters ($140) . . . and I got one. This meant a second 10m rig to use as an SSB generator with about one Watt output to drive the converter. My Atlas wouldn't hit the right part of the band so I ended up borrowing a Ten Tec Argonaut from Tufts Radio . . . bless Tufts. The converter only had about five Watts output, not nearly enough to tickle Oscar, particularly after going through a hundred feet of coax and a phasing section.

Sensing that I was going to need more than a little help with this whole matter I enlisted Sandy Cole W1PVF who drove up from Boston not a few times to work on the antennas, the equipment, the rotators and the feedlines. As things got closer to fruition Chuck Martin WA1KPS and Joe Polcari WA1PQE swung into action, digging up power supplies to run this and that, spending hours on the roof changing the feedlines and the connectors.

In line with needing more power at 432 MHz, I contacted TPL and eventually ended up with a not inexpensive 432 amplifier. Not inexpensive at all. But nice.

After checking out the system and getting it about ready to go, Chuck, Sandy and Joe came up one Sunday and spent the better part of the day getting everything ready. Oscar was due over in mode B at 8:10 pm according to our figures. We adjourned for a leisurely dinner at a nearby restaurant and then headed back to the shack, an hour in hand.

Chuck decided to check out the antenna rotating system . . . the pass would be almost directly overhead. He swung the beam upward and it stuck! Ooops. The three of them headed to the roof with a hack saw to hack off the back end of the antenna boom that was hitting the chimney, preventing the 180° swinging of the antenna vertically . . . then they needed a 10' step ladder . . . quite a deal in the black of night in November on top of a sharply peaked roof. With minutes to spare and much coordination on 52 via HTs the antennas were ready to go and the rig fired up.

Picture four people all tuning for signals, trying to grab the mike and zero in on received signals. There were several minutes of arms, legs, body language, and grunting before my persistence won out and I managed to get momentary control of both the transmitter and the receiver . . . and get a contact with WA6UAP . . . 5x5, he said. I gave him a 5x7. It was exciting. We'd made it.

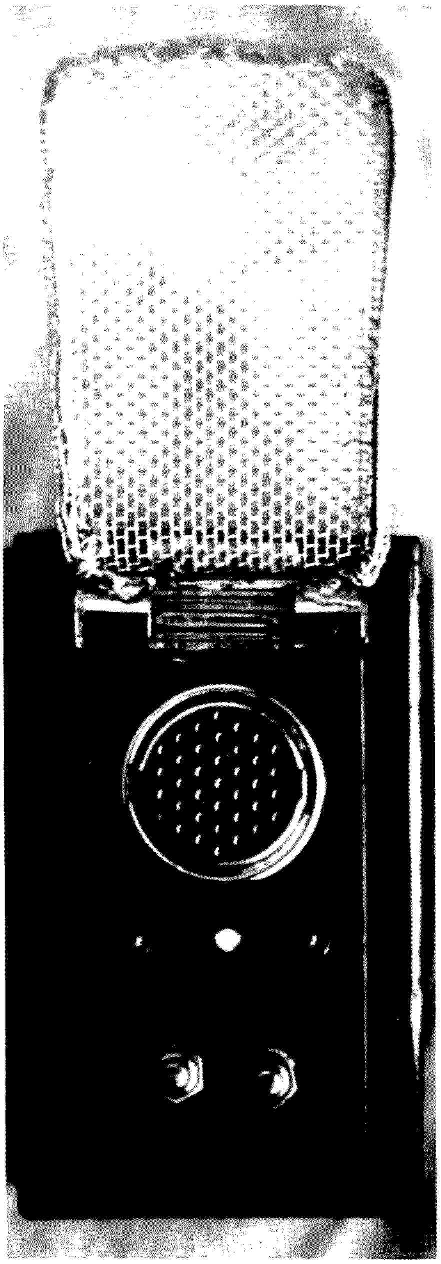
Chuck WA1KPS, Joe WA1PQE and Sandy W1PVF work to get the 73 Magazine *Oscar antennas into orbit.*

Trekkies, Build this Starfleet Communicator!

by
Marc I. Leavey, M.D. WA3AJR
10-J Tentmill Lane
Pikesville MD 21208



**TOP SECRET
CLASSIFIED**

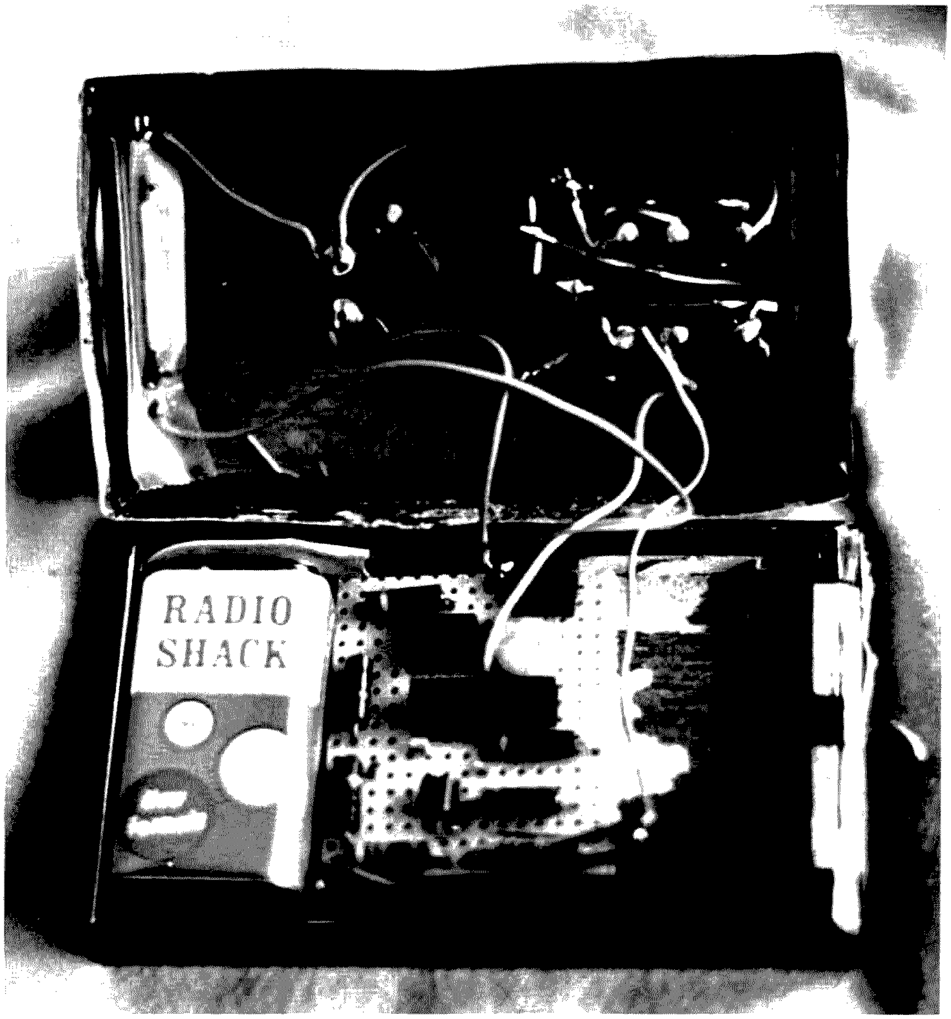
**FOR COMMAND
LEVEL USE
ONLY**

The plans contained herein are drawn from data in storage at Starfleet Archives, UFP, and are released for information only. Operation of communications devices within this sector of the galaxy is restricted under UFPCC regulations to authorized individuals only.

"Star Trek," a television show popular in the late 1960s, spawned a cult of followers that cannot be believed. There are Trekkies in all walks of life, particularly among college students, electronic engineers, doctors, and, it is hoped, hams. There are books, models, and national organizations devoted to perpetrating the culture of the United Federation of Planets. In this vein, I have designed and built a functional model of a Starship communicator.

The Communicator, as any dyed-in-the-wool (or velour) Trekkie knows, is the all-purpose, futuristic HT carried by all landing party personnel. Besides a basic, long range transceiver, the communicator also contains a transporter beacon for beaming up and an emergency distress signal for urgent transportation. This version, designed after the TV model, has all of these features.

On the front panel, there are the speaker/mike, three LED function lights, and two control switches. A hinged lid covers the controls, which serves the dual function of on/off switch and antenna. The



LED function lights represent ON (Green), HIGH POWER (Yellow), and EMERGENCY (Red). Two push-button switches control the HIGH-LOW power function, and the EMERGENCY beacon. Opening the Communicator lid not only turns the unit on, but produces the characteristic series of blips which identifies the hand-held device.

The circuit, shown in Fig. 1, is for the basic pulse generator that supplies the effects for the unit. The unijunction transistor is used as a simple oscillator, the output of which is fed to a 7493 4-bit binary counter. Four pulses are derived from this, in a one-half second gate, and fed to a 555, connected as an audio oscillator. The output of this goes to a speaker.

The complete communicator schematic is illustrated in Fig. 2. The LEDs are wired in series with the pulse generator, and no series resistors are needed, as current is effectively limited by the pulse generator. A 200 uF capacitor is needed across the battery to bypass internal resistance. Two SPDT push buttons are wired with the LEDs. One alternately selects the Green or Yellow LED, to represent LOW or HIGH power. The second switch normally shorts the Red LED. When depressed, the short is opened, lighting the LED, and a current is delivered to pin 4

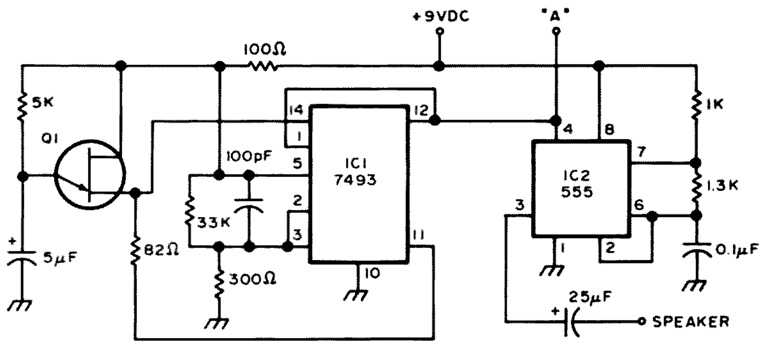


Fig. 1. Basic pulse generator.

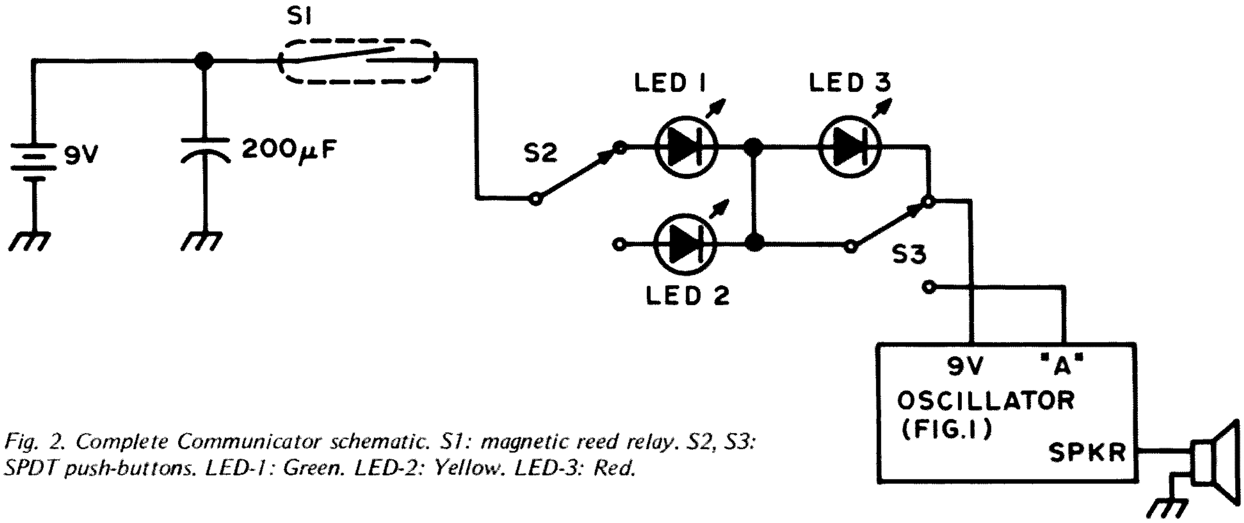

Fig. 2. Complete Communicator schematic. S1: magnetic reed relay. S2, S3: SPDT push-buttons. LED-1: Green. LED-2: Yellow. LED-3: Red.

of the 555, triggering a continuous oscillation.

Several techniques were tried for turning the communicator on when the lid was opened. The method finally settled upon was the use of a magnetic reed relay under the cover, with a small bar magnet mounted on the antenna lid.

Mechanically, the device is constructed in an appropriate sized, small wooden jewelry box. Such boxes are universally used by jewelers for necklaces, etc., and one can usually be scrounged from a wife or girlfriend. The speaker is a small, surplus earphone. Suitable types are available widely for a couple of dollars. A snap-in pipe bowl screen, with the snaps removed, serves as a miniature speaker grille. The LEDs are press-fit into the front panel, and the switches mounted conventionally. Fourteen-gauge wire is bent into a rectangle and covered with window screening for the antenna lid. Two rings from the center of a cheap ballpoint pen are soldered to one side, and the assembly mounted on a plastic tube, acquired from an old Bic pen. A small spacer glued to the bottom of the tube serves as a mount, and to keep the antenna assembly from slipping off. In order to activate the hidden reed relay, a small magnet is glued to the antenna, near the hinge. All of the electronics fit comfortably onto a 3 x 5 cm piece of perfboard, with the wiring done point-to-point. Detailed construction is left to the builder, but, with reasonable care, the finished result should delight any Trekkie.

I would like to extend sincere thanks to Robert Glaser WA3MSW, who aided immeasurably in the construction of the communicator. We would like to note that construction has been started on a small transporter. A shortage of dilithium crystals, however, has stalled the project. Any reader with an adequate supply is invited to write to the above address. ■

OPERATION INSTRUCTIONS
FOR
SF MOD. 6272 HHC

1. Stand in a reasonably clear area for transmission.
2. Open the unit with a gentle flick of the wrist.
3. Production of several coded blips and illumination of the green telltale indicate the unit is functioning and ready for use.
4. Speak clearly into the speaker/mike, remembering that this device has an instantaneous voice operated transmit and receive circuit.
5. If receiving station complains that your signal sounds weak, boost power by depressing the left push-button. The yellow telltale indicates high power operation. USE MINIMUM POWER TO GET THE MESSAGE ACROSS!
6. FOR EMERGENCY USE ONLY: Depress the right push-button. The red telltale comes on, and the automatic beacon is activated. When the button is released, the telltale extinguishes to conserve power, but the beacon is continuous. Assume transport position; beam-up should commence within 30 standard seconds.
7. This device is limited to one parsec communications range. As long as a Federation vessel or receiving monitor is within that range, communications will be possible.

A. E. Plavcan
P.O. Box 6173
Anaheim CA 92806

Synthesized receivers are gradually appearing in the marketplace. Their numbers will increase as the cost of complex ICs drops. They all operate basically the same, using the phase lock loop (PLL) technique of generating L.O. (local oscillator) frequencies. One crystal is used to generate the whole range of L.O. frequencies – each frequency as accurate as the crystal.

Here's a project that will provide you with several precise (.005%) frequency standards and also get you familiar with phase lock loops.

The heart of this unit is the NE562 phase lock loop. Internally it has a phase comparator, adjustable low pass filter, a VCO (voltage – controlled oscillator) and two outputs. It also has provisions for inserting a programmable divider between the phase comparator and VCO, thus permitting frequencies to be changed.

The frequency range of this device is 1 to 10 MHz in 1 MHz steps, with an accuracy of .005% at each frequency (greater accuracy is possible with a closer tolerance xtal). The output is a symmetrical square wave at each frequency that is useful as a scope timebase calibrator, checking bandwidth and frequency response of HF amplifiers, calibrating communication receivers with the 100 kHz output, or as a "clock" for future IC projects.

All of the ICs (including the NE562) are readily available from electronic mail order houses. The remaining few parts you can get from your junkbox. They are all "or equivalent."

How It Works

Before we get into the details of construction, a little basic operation of phase lock loops may be helpful. A basic phase lock loop consists of a phase comparator, a VCO and a low pass filter, as shown in Fig. 1.

The phase comparator (or phase detector) has two inputs, the reference frequency and the output of the VCO. The output of the phase comparator is a dc control voltage proportional to the phase difference between the two input frequencies. The control voltage equation is $V_c = K(\Theta_{ref} - \Theta_{vco})$ where K is a constant in volts/radian and $(\Theta_{ref} - \Theta_{vco})$ is the phase difference in

A Synthesized IC Frequency Standard

radians. Now the VCO frequency is controlled by a dc voltage. As the frequency of the VCO tends to drift, a phase error develops and is fed back to the comparator which compares it with the reference signal and produces a dc voltage that changes the frequency of the VCO in the direction that will reduce the phase error. Since the VCO is controlled by a dc voltage, any ripple on the voltage will FM (frequency modulate) the VCO. That's the purpose of the low pass filter between the phase comparator and

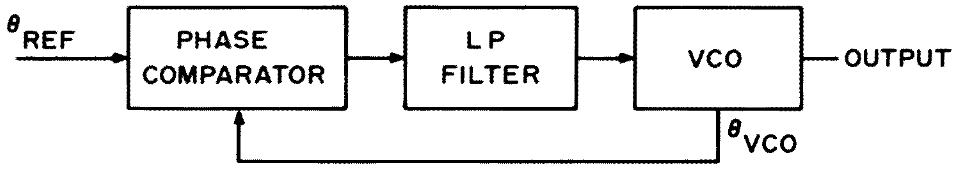

Fig. 1. Basic phase lock loop.

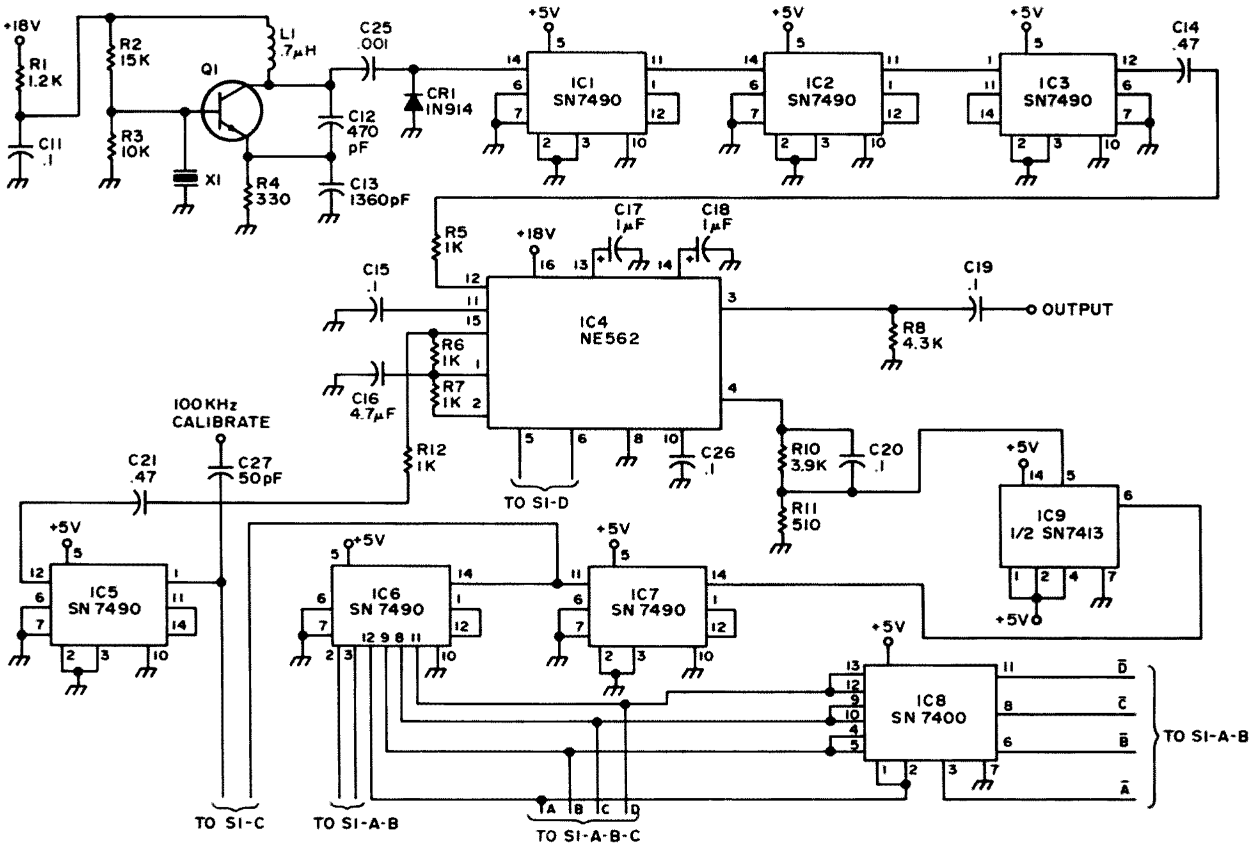

Fig. 3. Schematic diagram. R1-R12 — ¼ Watt carbon resistors; C11, C15, C19, C20, C25, C26 — 20 V disc; C12 — silver mica Elmenco DM19; C13 — silver mica (2 — 680 pF in parallel) DM19; C14, C21 — 35 V Sprague type 196D, 474X0035HA1; C17, C18 — 35 V Sprague type 196D, 105X0035HA1; IC1, IC2, IC3, IC5, IC6, IC7 — SN7490 decade counter; IC4 — NE562 phase lock loop; IC8 — SN7400 NAND gate; IC9 — SN7413 NAND Schmitt trigger; Q1 — 2N5172; X1 — 10 MHz .005% crystal (series resonant) from Jan Crystals, 2400 Crystal Dr., Ft. Myers FL 33901; L1 — .7 microhenry inductor; S1 — rotary switch 4 pole 10 position, Centralab PA-1015.

VCO, to reduce this ripple. It also helps to set the capture range of the loop.

One drawback of Fig. 1 is that it will only work at one frequency. The output frequency is the same as the reference and there is no way to change the frequency. If we put a variable divider (÷N) between the VCO and the phase comparator feedback path, we can vary the frequency of the VCO, then divide it down so that the phase comparator inputs are always the same. This allows us to change the VCO yet maintain the same inputs to the phase comparator. See Fig. 2.

The control voltage equation now is:

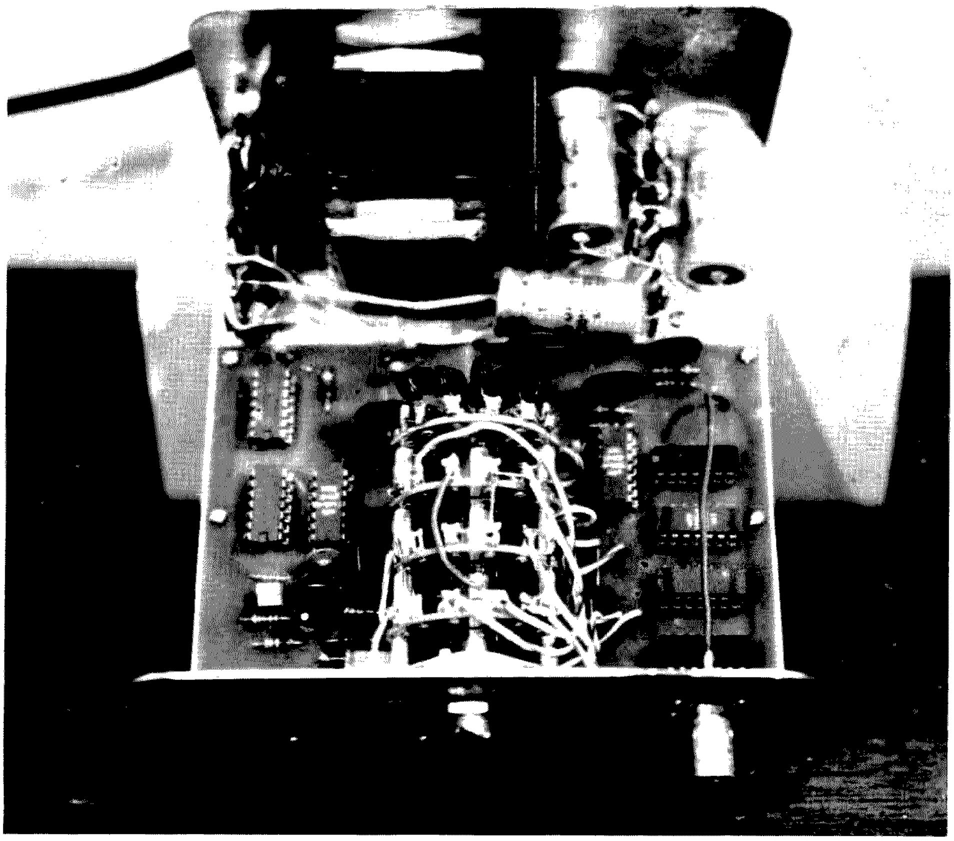
$$V_c = K\left[\Theta_{ref} - \frac{\Theta_{vco}}{N}\right]$$

where N is the number programmed into the variable divider. The operation of this system is the same as the basic loop described above.

The Reference Circuitry

The circuitry of Q1 is a 10 MHz .005% crystal controlled oscillator. R2 and R3 is the bias network. C12 is the feedback capacitor and is part of the resonant tank along with C13 and L1. If you don't have a .7 uH inductor for L1, you can make your own by winding 19 turns of #30 magnet wire (closewound) on a 1/2 Watt resistor (100k or larger). C13 is 2 680 pF capacitors in parallel. X1 is a 10 MHz .005% (series resonant) crystal.

C25 is a coupling capacitor to the following IC. Normally, a shaping circuit would be included here. But the rise and fall times at 10 MHz are adequate to trigger the IC. We will need a diode though (CR1) to clip the negative going transitions and prevent V_{eb} breakdown in the IC. IC1, IC2, and IC3 are wired to divide by 10. The output of IC3 is at 10 kHz. This will be the reference signal for the phase comparator. You'll note that IC3 is wired a little differently than IC1 and IC2. This is done so that a symmetrical 10 kHz square wave is fed to the comparator. R5 reduces the drive level into the comparator.



The Programmable Divider Circuitry

Pin 4 on IC4 is one of the VCO outputs. R10, R11 and C20 couple the signal out while still maintaining a dc path for the emitter in IC4. This signal is fed into IC9 which is 1/2 of an SN7413. The SN7413 is a dual Schmitt trigger. A Schmitt trigger improves the rise and fall transitions over a wide range of input frequencies. Since the output frequency changes from 1 to 10 MHz, suitable transitions are necessary over the full range of frequencies to insure positive triggering for the following IC. IC7 is a prescaler. It divides the output of the VCO by 10. This was done so that the programmable divider following (IC6) will operate at a lower range of frequencies, from 100 kHz to 1 MHz. Propagation delays and race conditions can cause false triggering at high frequencies. IC6 is the programmable divider. This is where all the switching of the system takes place. Basically, we want to divide all frequencies out of the VCO so that the output of the programmable divider is always 100 kHz. For example, if the VCO is at 5 MHz, the prescaler reduces it to 500 kHz and the programmable divider is switched to ÷5 and the output is 100 kHz. If the VCO is at 9 MHz, the programmable divider is switched to ÷9 and the output is 100 kHz. IC6 can be switched from ÷2 to ÷9. Now at 1 MHz the output of the prescaler is 100 kHz. We don't need the programmable divider here so it is simply bypassed. The output of IC6 is further divided by 10 in IC5, wired to provide a symmetrical 10 kHz square wave out. R12 is the same as R5, to reduce the drive to the phase comparator. R15, CR2 and CR3 are part of the ÷7 decoding. CR2 and CR3 can

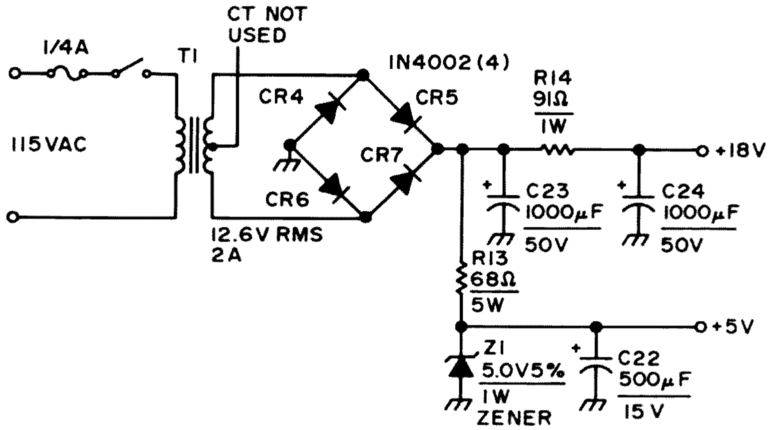


Fig. 4. Power supply. R13, R14 — carbon resistors; C22 — 15 V; C23, C24 — 50 V; T1 — 12.6 V rms power xfmr Allied 6K36HF; Z1 — 5 V ± 5% zener diode 1N4733A; CR4-CR7 — 1N4002 (PRV 100 V, 1 A).

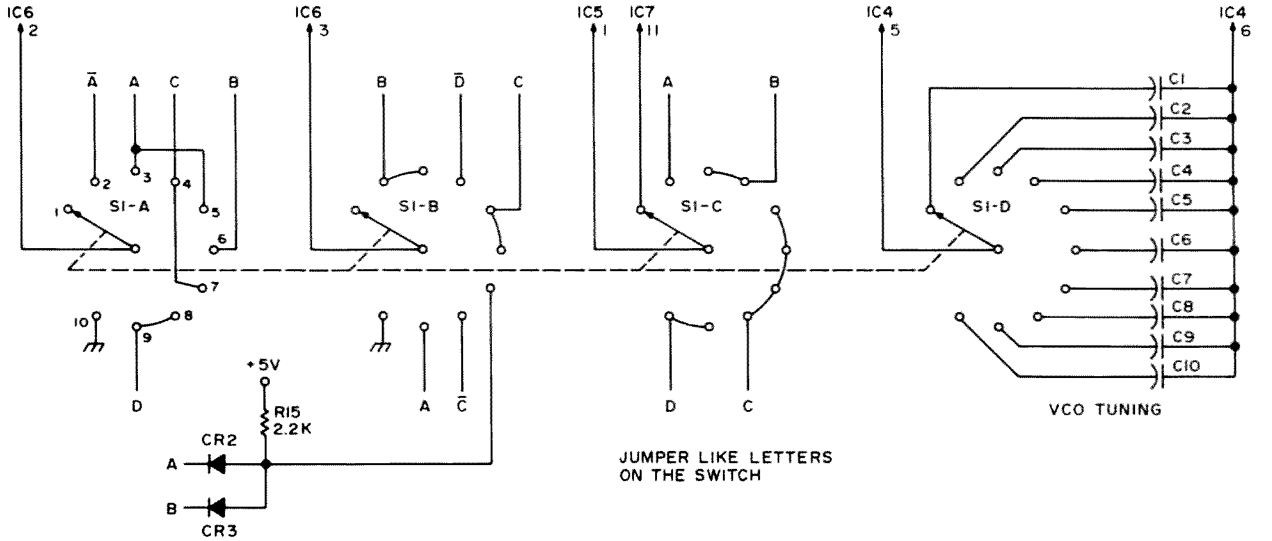

Fig. 5. Programmable counter switching and VCO tuning diagram. C1-C10 – Elmenco DM10 or DM15 silver micas (see text); CR2, CR3 – 1N118 (germanium).

be any general purpose *germanium* diodes. IC8 inverts the A, B, C, D outputs of IC6 to provide the $\overline{A}$, $\overline{B}$, $\overline{C}$, $\overline{D}$, outputs to decode the programmable divider.

So now we have described the development of the two input signals to the phase comparator, one signal as a fixed reference (Θ_{ref}) and the other containing the phase error information (Θ_{VCO}) from the VCO.

Pins 5 and 6 on the NE562 (IC4) are provided for capacity tuning the VCO. As each frequency is switched, the capacitor across pins 5 and 6 has to be switched. The free running frequency of the VCO has to be tuned within the capture range of the loop. As mentioned earlier, the low pass filter determines the capture range of the loop. C17 and C18 on pins 13 and 14, respectively, on IC4 are the low pass filter capacitors. When the free running VCO is tuned within approximately 300 kHz of center frequency, the loop will lock. The following chart gives the approximate tuning capacitors for F_C at each frequency. They should all be silver mica.

Construction

Except for the power supply and divider-frequency switch, all the parts are mounted on the 3-7/16" x 5" etched PC board. Holes are provided on the board for all the wires going to S1. Sockets can be used for all the ICs to simplify troubleshooting, if necessary, or they can be hard wired to the board. I used the Molex terminals available at electronic stores.

They're inexpensive and are satisfactory sockets. Holes are also provided to strap all the IC power connections. Use magnet wire. Several circuit jumpers are also needed as shown on the parts layout. C1 – C10 should be mounted right on the switch (S1), with all the common points brought together in the center. Run a wire to the circuit board.

Final Checkout

Before applying power, check that all the jumpers are in and the ICs are mounted in the correct positions. Set the frequency switch to the 1 MHz position. After you're sure everything is OK, apply power and check that the supply voltages are present. +18 volts should be at the junction of R14 and C24. R14 can be changed to make it +18 volts. +5 volts should be at the zener diode. A counter would come in handy here for the following check but a scope will do. A triggered scope is even better. At the junction of C14 and R5, there should be a 10 kHz square wave approximately 3 volts peak to peak. This one point checks that the oscillator is working and also the divider chain. The same wave shape should be at the junction of C21, R12. If it is, the loop is locked at 1 MHz .005%. Repeat the above for each position of the frequency switch. If you reach a position where both wave shapes are not the same, check the switch wiring of the programmable divider. If it's alright, you'll have to adjust the tuning capacitor for that particular channel. Calibrate the scope using the reference 10 kHz signal. Display one square wave for 10 cm on the scope (junction C14, R5). Move the probe to the junction of C21, R12 and adjust the tuning capacitor until the same wave shape appears.

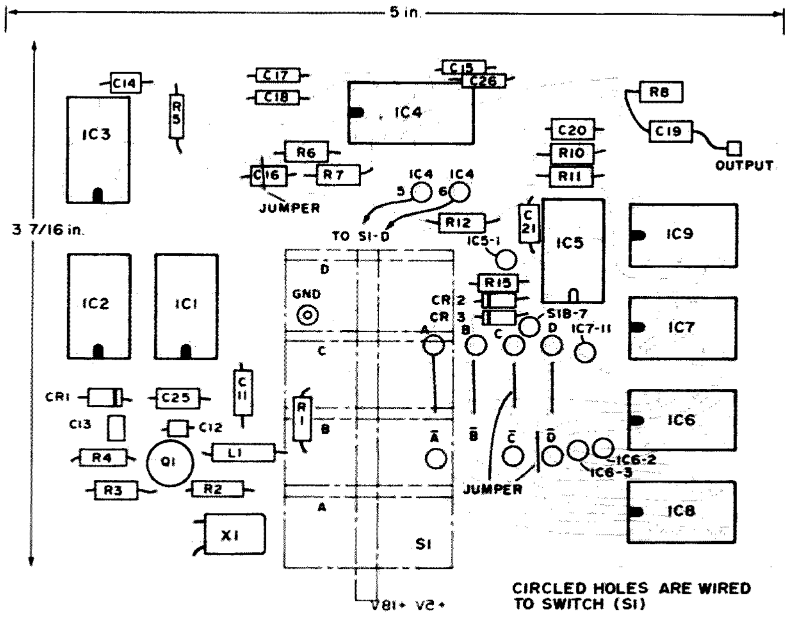

Fig. 7. Parts layout.

If the output is to be used as a "clock" to drive TTL circuitry, the circuit in Fig. 8 is suggested.

Use low capacity cabling on the output if you're going to run it any distance to preserve the wave shape. With the front panel switch in the 2 MHz position, a symmetrical 100 kHz signal is available on the front panel for calibrating communication receivers; simply couple the output (loosely) to the antenna input. ■

You Can Make Photo PC Boards

by
John Harrington
5132 Marcella Avenue
Cypress CA 90630

Construction of high-quality printed circuit boards, unfortunately, has never been a simple matter. Over the years, having made hundreds of boards, I have tried many methods, some simple, some complex, some cheap, some expensive, with varying degrees of success. The method described here has been in use for over a year now, and I am very pleased with the results. It allows me to make any desired number of high-quality boards with minimum expense and effort. Although there is nothing "new to the art" here, the method described for making negatives is one which I haven't seen described in amateur literature.

The steps to follow to make the boards are as follows:

1. Make up the "master artwork."
2. Prepare a negative from the artwork.
3. Clean and photo-sensitize the copper-clad board.
4. Expose the board through the negative.
5. Develop the exposed board.
6. Etch the board.
7. Plate the board if desired for corrosion resistance and appearance.

Don't let the imposing-looking list above discourage you – each step, in itself, is simple, and with reasonable care, is goof-proof. Let's take the list one at a time.

Preparing the Artwork

Start with a generous size sheet of transparent mylar or acetate sheet, about a centimeter bigger on each side than the size of the board you wish to make. If you are copying a published circuit which has full-size layouts, just stick the mylar down with masking tape over the published circuit. Then, using either india ink or commercial prepared patterns and tape, trace the circuit onto the mylar. If you are designing your own layout, tape the mylar sheet down on a piece of grid paper with 1/10" line spacing. This is very helpful as a device to keep your lines straight, and keep the component spacing and layout optimum. Most ICs and many other parts use lead spacing which are multiples of 1/10 of an inch – the grid paper makes it easy to locate component leads precisely on the layout. I use commercially available opaque sticky tape for conductor lines and component pads. Try to arrange the components to minimize the number of crossovers – sometimes a simple re-arrangement will eliminate several cross-overs.

When the layout is finished, check it against the original artwork or schematic to be sure it is correct. Don't overlook the fact that your layout is a *bottom view* of the

completed PC board, so your component pins must be connected properly for a bottom view. Be particularly careful with ICs – the manufacturer's drawings generally identify leads with a top view. I find it very helpful to redraw the IC on a scratch pad showing the bottom view of the pins and refer to it while drafting the circuit. This really helps when you are trying to cram ten or fifteen 14 or 16-lead ICs in a small layout. If you find you have made a mistake, just peel off the incorrect pattern and stick down a new one. If you are using india ink and wish to change the circuit, the easiest way I have found is to stratch off the incorrect part with the blade of a sharp knife, being careful not to damage the mylar. Then, redraw the circuit.

Preparing the Negative

To do this operation, we will expose some photographic film to light through the artwork. This is a darkroom technique, so it needs to be done under a "safelight." A safelight is simply a common lamp with a filter over it which only allows certain colors to pass through. These colors are chosen for their wavelength; the film we will be using is relatively insensitive to red light. Therefore, we can use a red filter and illuminate the work area without danger of ruining the film.

In use here is an inexpensive safelight holder with a Kodak 1A filter, and a 25W household bulb. With this mounted over the work area, it will provide plenty of illumination to clearly see each operation.

Inexpensive lithographic black and white film is used for several reasons. It is a relatively "slow" film which means it takes more light for a longer time to expose; therefore, it is much more forgiving of errors such as outside light leaking into the darkroom or overexposure. This type of film is especially designed for high contrast. Also it is easy to obtain this film at most any photo supply shop, and the cost for a piece of 10.1cm x 12.7cm (4" x 5") film is about 10¢.

Exposing the film is best done in a "contact frame." This can be as simple as sandwiching the artwork and film between a piece of flat black paper and a piece of clear glass. The glass serves only as a weight to hold the artwork and film in close contact to keep light from leaking under the black portions of the artwork. A more elaborate contact frame can be constructed or bought, but will only make the work more convenient, not better. I use a 150W flood light for exposure at a distance of 61cm (2'), and a 2-second exposure time, using my wrist watch and my finger on the light switch for timing. The two chemicals for development can be bought at the same store as the film. The developing bath I use is a 2-part solution which is mixed together in equal quantities just before use; the unmixed solutions can be stored for long periods without degradation. The "fix" solution can even be reused over and over again, by storing it in an air-tight bottle, but it is so cheap that I use fresh solution each time. The developing bath, however, must be discarded after a couple of hours use, as its performance degrades rapidly with use. Follow the manufacturer's directions when mixing the chemicals from the packages. You will need three developing trays, of a size sufficient to hold the film under the solutions. These are generally shallow black plastic trays and are very inexpensive.

Prepare the trays as follows: line up the trays, side by side, about 15.5cm (6") apart. These trays, from left to right, are for developing, washing and fixing. Pour equal quantities of the 2-part developing solution into the developing tray until it is about half full. Then half fill the wash tray with ordinary tap water. The fix tray is half filled with the fix solution.

Now we are ready to make the negative. Cleanliness is very important in any photographic work – dirt or dust smears can show up on your completed work. Turn on your safelight and extinguish all other lighting. Open the package of film and carefully open the light tight inner container. Take out a piece of film and immediately close up the package again so you won't forget later. Take a good look at the piece of film, handling it only by the edges. You will notice that one side is shiny, while the other

2. Bishop Graphics, Inc., 7300 Radford Avenue, North Hollywood CA 91605 offers a catalog of drafting aids for quantity users.

Many ham-oriented electronics supply houses have G. C. displays with all necessary materials to make everything except the negatives.

Ferric chloride can be obtained in gallon quantities at many electronic or chemical supply houses.

Hydrochloric acid for etchant rejuvenation can be obtained from chemical suppliers or drugstores.

has a dull finish. Place the dull side down in your contact frame. Then put your artwork down on top of the film, centering it carefully, and place the clear glass cover down on top of that. Expose for approximately 2 seconds at a distance of about 61cm (2'). Open the frame and extract the film. Place the exposed film in the developing solution, shiny side up and rock the tray slightly to agitate the solution. After a few seconds, depending on the temperature, you will see the image start to form on the film. When the image seems to be fully developed, wait another 10 or 15 seconds. Then reach in and grab the film by the edge and pull it out. Let it drip for a few seconds, and then, still holding it by the edge, slosh it around in the wash solution (water) for about 30-45 seconds. Pull it out, let it drip and place it in the fixer. Rock the fix tray slightly to agitate for about 5 minutes. After the first couple of minutes in the fix tray, you can turn the normal room lighting back on. The final step is to wash the completed negative off in warm running water for a few minutes and hang it up to dry. At this time, hold the negative up to the light and look it over. The black areas should be really opaque, and the clear areas should be perfectly transparent, with no smearing or fuzzy lines. A little experimentation with exposure and development times will optimize your particular setup. Frankly, I was amazed at how easy and non-critical this process is, using lithographic film, compared to the elaborate setups used to expose and develop high-speed color film that requires total darkness, careful temperature control and precision timing of various steps. My workshop is in my unheated garage, and I have made beautiful negatives when the ambient temperature was as low as 60°F. The chemicals work a little slower at low temperatures, so just develop slightly longer.

Sensitizing the Copper-clad Board

While ready-made photo sensitized boards can be purchased, it is much cheaper to do it yourself. The photoresist is made by many different companies, but about the most convenient and easily obtained is a spray can made by G.C. Electronics. This resist is most sensitive to the ultraviolet portion of the light spectrum, so a common yellow "buglight" can be safely used for the safelight. Also you will need some means of drying the board after cleaning, and after spraying on the photoresist. A simple forced air oven can be made by blowing hot air from a small electric heater into a cardboard box – this is the method I use, see Fig. 1. Monitor the temperature in the box with a thermometer. The first step is to thoroughly clean the copper-clad board. Scrub it with steel wool soap pads, using plenty of water, until the copper is bright and shiny. Test for cleanliness by letting water flow across the surface – dirt or fingerprints will make the water "bead" or "break." It is very important to have the copper surface clean to insure that the photoresist will adhere properly. After cleaning, and for all subsequent operations, handle the board only by the edges. Wipe the board with a clean, lint-free rag, and place it in your "oven" to dry. Dry for about 20 minutes at 100 to 115° F, then remove and let it cool to room temperature. The next steps must be done using only your yellow "bug" safelight for illumination. Lean the dry, clean board up against a newspaper backdrop and spray it well with the photoresist. Get on a good, thick coating and be sure to cover the complete copper surface. Daub off any excess on the bottom edge of the board, and place it into the oven, leaning vertically against the back wall. It is important to dry the photoresist quickly, as airborne dust particles will stick to the surface until it dries. Dryout will take about 15-20 minutes at 100 to 115° F. Do not overheat the photoresist as this will destroy its properties.

Exposing and Developing the Board

While the photoresist is drying in the oven, get your contact frame ready again. The G.C. photoresist instruction calls for exposure using ultraviolet or sunlight, but I get good results using the same 150W photoflood lamp as is used for exposing the film. Since the resist is not as sensitive to this light as to ultraviolet, it takes longer to properly expose.

Place the coated board in the contact frame, and center the negative over the top. Cover the top with the glass. Expose the board for about 8 minutes at a distance of about 30.5cm (1'). After exposure, plunge the board in the G.C. developing solution for about a minute, using slight agitation. The image should form quickly as the unexposed resist washes off in the solution. Pull the board out and let the solution evaporate for

a few minutes. The normal room lighting can come on now, as the board is no longer light-sensitive. Rinse the board off with warm water and dry it with a soft cloth, using a blotting motion. Look the board over very carefully to make sure the pattern is complete, and has no pin holes or breaks. Defects are generally caused by a lack of cleanliness. Touch-up can be done with a resist pen, if necessary.

Etch the Board

My favorite etchant is ferric chloride, which can be "rejuvenated" and used over and over. I use a large plastic dish about 20.4cm (8") square and 10.2cm (4") deep about 2/3 full of the ferric chloride. Heat speeds up the etching rate, so a glass aquarium heater is immersed in the solution to heat it to about 100°F. CAUTION: Never use any aluminum around ferric chloride as it reacts very violently. In fact, it is best to keep any metal away from your etching tray. To further speed up the etching process, you may use air from a small aquarium pump to "bubble etch" the board. Immerse a large aquarium aeration stone in the solution and float the board on the surface, face down. The pump air bubbling up from the stone through the ferric chloride etches the board very rapidly. A fresh batch of ferric chloride, using bubble etching, will completely etch a board in about 5 minutes. After repeated use, the etchant becomes saturated with all the copper it has dissolved until it finally refuses to etch away any more copper. Some of this copper can be removed from the solution by the addition of muriatic acid (hydrochloric).

Carefully add about 2 fluid ounces of the acid per quart of ferric chloride, and let air bubble up through the solution for 12 to 24 hours. This will rejuvenate the etchant enough to make it very active again. When it again becomes saturated, simply repeat the rejuvenation. The solution gets darker and darker each time, but I have observed no adverse effects. I can't say how many times this rejuvenation can be successfully carried out, since I have been using my present gallon for almost two years. I have added about a quart of muriatic acid over this period, and it is still going strong. I owe this idea, and the bubble-etching technique, to Larry Hutchinson, who had an excellent article on the subject in the September, 1971, issue of Ham Radio.

After etching the board, rinse it thoroughly with running water. Strip the resist from the unetched areas of the board with acetone which is much cheaper than most commercial stripping solutions. Saturate a small piece of cloth with the acetone and scrub off the resist, then rinse again with water and dry.

Final Touches

If desired, the board can now be trimmed to size, drilled and the components soldered in. However, a much better looking board can be made by plating the copper with a tin lead compound. This not only makes the board much easier to solder, but also insures the copper surface will not corrode. I use an electroless plating solution made by The Dynachem Corporation, Number EBS-250. To use, heat some of the solution in a pyrex dish to about 140° F on a hotplate. Dunk the board in, and in about 20 minutes the plating is complete. The coating is not very thick, only about a tenth of a mil, but is plenty for our purposes. The Shipley Company in Newton MA also makes a product called LT-27 immersion tin, but I have not tried it. After plating is completed, rinse the board in hot water and dry. You now have a high-quality printed circuit board which can be duplicated easily and exactly by reusing your negative. Be sure to store your negatives and artwork where they will not become dirty, scratched or otherwise damaged. I put mine in manila envelopes and store them in my card file.

Conclusion

The techniques described above represent the optimum answer in my case to the tradeoffs between cost, complexity and quality. My boards now rival commercial boards in appearance and repeatability.

However, some features of commercial boards are either too expensive or complex at this time to duplicate in the average home workshop. For instance, plated-through holes, multi-layer construction, wave soldering and spray etching. In addition, making double-sided boards, although I have done it, is still too difficult and time-consuming to justify in most cases. I am still looking for cheap and simple solutions to the above problems. In the meantime, try it my way – you'll like the results. ■

Adding An Ammeter to Your Car

by
W. J. Prudhomme WB5DEP
1405 Richland Avenue
Metairie LA 70001

In an effort to simplify the operation of automobiles, most car manufacturers have, for many years, incorporated an "Alternator Indicator Light" on the instrument panel in lieu of the ammeter of days gone by. While this "Indicator Light" requires less attention while you are driving, it does not give you complete information on the state of your electrical system.

A recent experience with my car brought this fact to light and convinced me that my car should have an ammeter. Over a period of weeks, I was unaware that the output of my alternator was steadily deteriorating and not charging the battery properly. Eventually the battery completely discharged and left me stranded away from home. The outcome from the experience was that I had

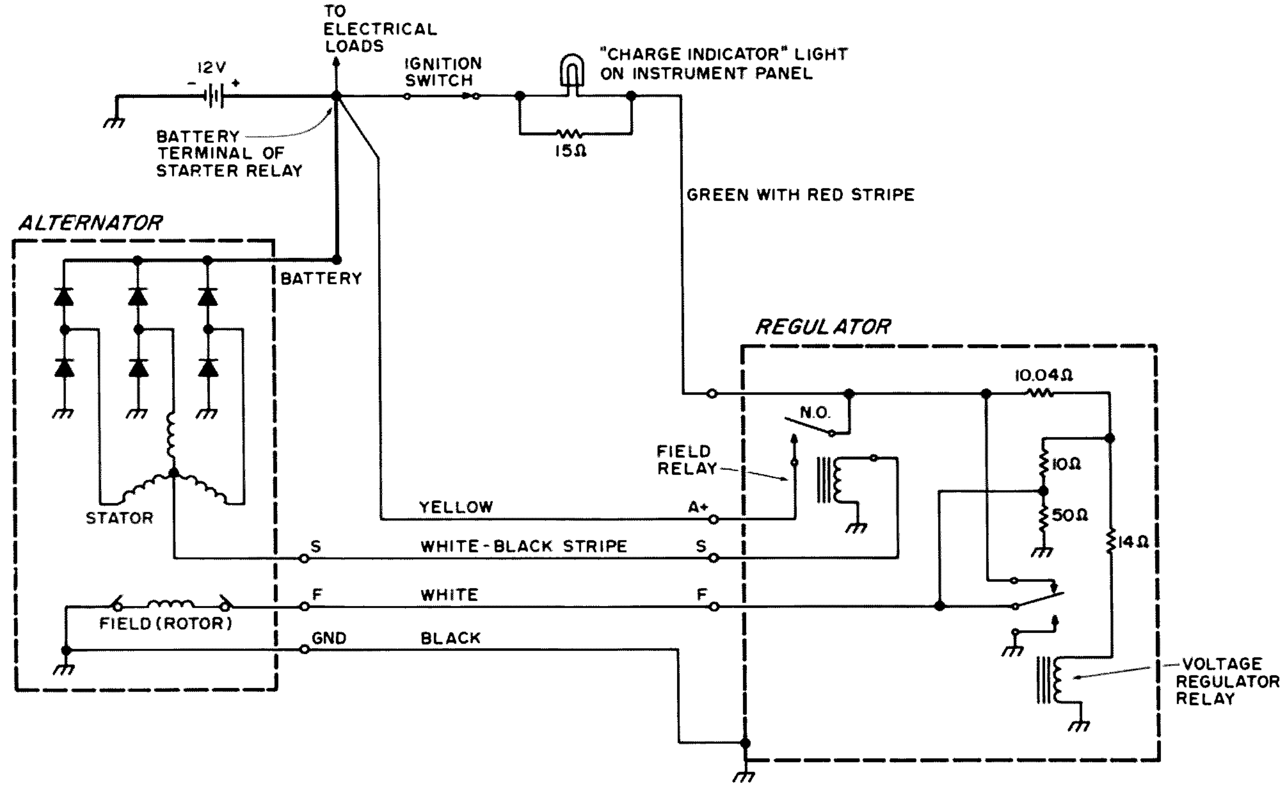

Fig. 1. Ford electrical system with electromechanical type regulator. (Other electrical systems are similar.)

to install a new alternator and I came very close to completely ruining a relatively new battery. During the entire time that the alternator was failing, the indicator light on the instrument panel would turn off during normal driving indicating that the alternator was "charging" and apparently, according to its indication, there was no problem. It occurred to me from this experience, that it would be better to have some type of indicating ammeter which would indicate the state of the system as to whether the battery was being charged or discharged. This article describes a method of installing an ammeter into your existing automobile system without any changes or modification to the existing system and at a very low cost. In fact, it is so easy and inexpensive to incorporate it into your system that you shouldn't be without one, especially if you operate mobile radio equipment which adds an additional drain to your car battery.

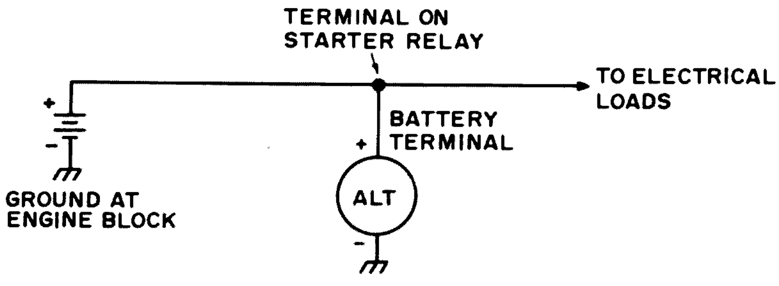

Fig. 2. Simplified diagram excluding the regulator.

Advantages

The system I am about to describe has several advantages which make it attractive for an amateur to install in his car. These advantages are:

(1) All leads are at ground potential, so there are no problems with shorts in the system or the necessity of fusing the conductors.

(2) No heavy currents pass through the indicator, so small conductors may be used.

(3) Although the system makes use of shunt resistance to measure the current, a unique method is used so that no additional voltage drops are added into the present electrical system.

(4) It is very easy to add to your existing electrical system – no changes in existing wiring.

(5) The ammeter circuit can easily be adapted with a switch and resistor to read system voltage.

(6) It is inexpensive to install and depending on the type of meter movement you install, the cost can range anywhere from $1.50 to $7.00.

With these advantages, I feel certain that more amateurs will want to install an ammeter to their car electrical system to monitor the battery charging rate.

Typical Electrical System

Referring to Fig. 1, a diagram for Ford Electrical System is presented. This system incorporates an electromechanical voltage regulator and is the type used in my own car (although other systems such as General Motors are similar). As you can see, the alternator consists of a stationary 3Ø stator winding in which the output goes to a set of diode rectifiers. These diodes are arranged in such a manner that the output at the battery

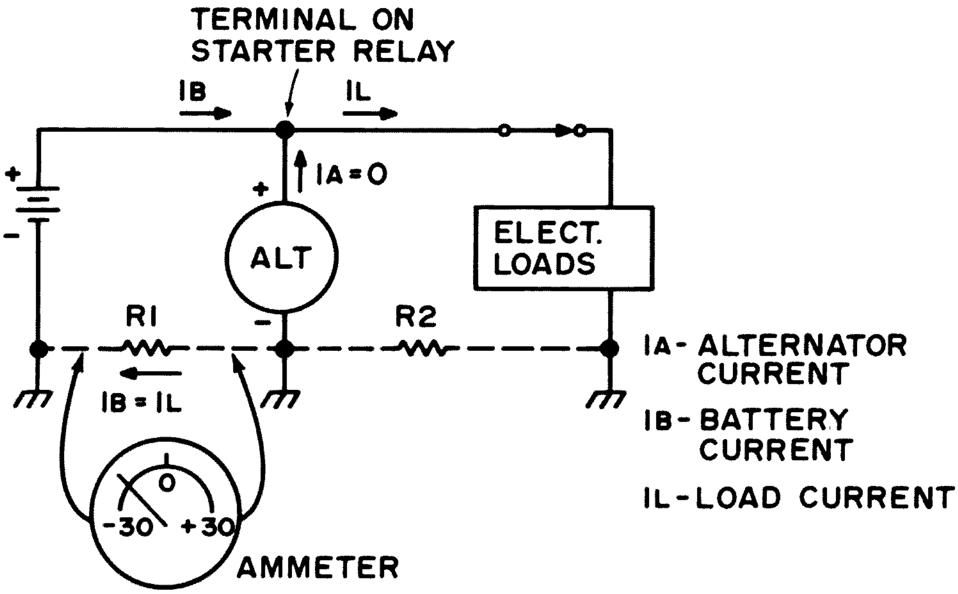

Fig. 3. Basic electrical system showing resistance in ground path circuit – discharge condition (engine stopped and electrical loads connected).

terminal of the alternator is always positive. There is a rotating field which excites the stator winding during normal operation. As you can see, the alternator is always connected directly to the battery through a terminal block, and it is at this point that the other electrical loads in the car are connected. The neutral from the stator winding is grounded through the field relay winding in the voltage regulator and its contacts are normally open. When the ignition switch is turned on, a certain amount of voltage from the battery is connected directly to the field through the charge indicator light on the instrument panel. After the engine is started, and the alternator is producing current, the stator current flowing through the field relay winding pulls the contacts down which in turn bypasses the indicator light on the instrument panel. In other words, as long as the alternator is producing current of sufficient magnitude to hold the field relay contacts closed, the charge indicator light will be off, indicating that the alternator is producing current.

This system works fine as long as all elements in the system are operating under normal circumstances. However, as long as the alternator is capable of producing enough current to operate the field relay contacts, the charge indicator will be extinguished although there may not be enough current produced to charge the battery. Under these circumstances, the charge indicator light does not give a true picture of what is happening in the system, and it also does not indicate the amount of discharge or charge condition of the battery.

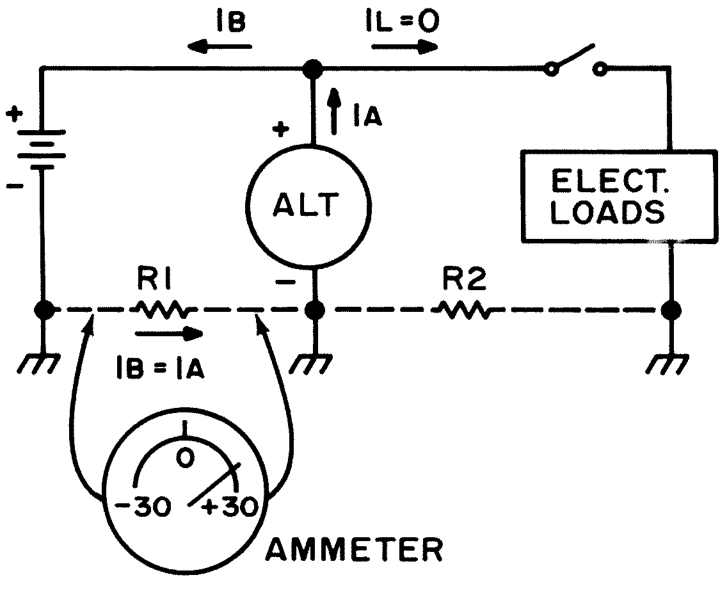

Fig. 4. Charging condition — engine running with electrical loads off.

Referring to Fig. 2, I have indicated a simplified diagram of the battery-alternator connections without the regulator or field windings shown. As you can see, the alternator is continuously connected to the battery and to the other electrical loads usually at the terminal of the starter relay. During normal operation of a car, the alternator performs two functions. First, it produces enough current to operate the electrical loads in the car and second, it produces current to flow back into the battery to charge the battery during normal driving conditions. There may be a time when a faulty alternator does not produce enough current to do both, and it is under these circumstances that you may end up with a dead battery and no forewarning of that condition.

Also, from the diagram, it appears logical that the correct location for a charge indicator would be somewhere in the battery circuit, either between the positive terminal on the alternator and the positive terminal on the battery, or between the negative terminal on the battery and ground. This indicator should have a zero center scale so that it would indicate a discharge condition (battery drain) or indicate a charging condition from the alternator. The usual method of connection is to add some type of shunt into the system in order to sample the amount of current flowing in the conductors to provide an indication. However, if a shunt is added into the circuit (such as the ¼ Ohm shunts which are used on most automotive ammeters you can purchase at a store) you incorporate an additional voltage drop into the system. By accident, I determined a unique feature of automobile systems which you can make use of in what I call a built-in shunt condition.

Ground Paths

Referring to Fig. 3, I have indicated a simplified electrical diagram showing electrical loads connected to the system. This is a discharge condition in that the engine is stopped and there is no output from the alternator. Since the alternator remains connected to the system, it would appear that some drain would also result from the alternator. However, keep in mind that the alternator windings are connected to the positive terminal through diodes, and therefore, no reverse current can flow through the alternator. Under this condition, the alternator current $I_A = 0$. Applying Kirchhoff's Law which states the sum of the currents entering a junction is equal to the sum of the currents leaving the junction, we have the battery current I_B entering the terminal and the load current I_L leaving that junction.

Since the alternator current is equal to zero, $I_B = I_L$, or simply stated, the battery is supplying all of the required power to operate the load.

Let's discuss for a minute the theoretical versus actual conditions. We normally think of the negative terminals of the battery, alternator and loads all being grounded together so that all negative terminals are at the same potential. However, in most cases, we are depending on the frame of the car as a ground return path, and since steel is a mediocre conductor, there is always some inherent resistance incorporated into all automobile electrical systems. I have represented this resistance as being R1 between the battery negative terminal and the alternator negative terminal and R2 between the alternator and the electrical loads. Applying Ohm's Law, the voltage drop across R1 would be:

$$E = (I_B)(R1)$$

Granted, the resistance of R1 is small, in the neighborhood of 0.01 to 0.1 Ohms, but the currents are very large – in the neighborhood of 10 to 30 Amps (except during starts when it is much higher). Consequently, the voltage drop across R1 is a measurable quantity and can be used to indicate which way the current is flowing in the battery-alternator loop. This is shown on the meter in Fig. 3 as a discharge situation.

Fig. 4 is a diagram of a basic charge condition in which the engine is running and no loads are connected. Again, applying Kirchhoff's Law with $I_L = 0$ we have: I_B is equal to I_A, and the voltage drop across R1 is $E = (I_B)(R1)$, but is of the opposite polarity of the discharge condition in Fig. 3. As the battery becomes charged, the alternator current charging the battery gradually tapers off and so will the voltage drop across R1 so we get a direct indication of the condition of the battery, and we know exactly when it has reached full charge condition.

In Fig. 5 we have a diagram showing normal operation of the vehicle in which the engine is running and certain electrical loads are connected. Under this situation, again applying Kirchhoff's Law, we have I_B and I_L leaving the terminal and the alternator current, I_A, entering the terminal. Stated as an equation, $I_A = I_B + I_L$. This means that the alternator has to supply enough current to operate the electrical loads and charge the battery at the same time. Of course, as the battery becomes fully charged again, the battery current will gradually taper off, and the alternator will be operating mainly to supply current to the electrical loads connected to the system.

Ohm's Law Applied

It is apparent that there will be some voltage drop which can be measured across this ground path resistance, but just exactly how much will be measured and how can it be utilized in a charge indicator?

Let's take for example, that the ground path has a resistance of only 0.01 Ohms and that a typical alternator is capable of producing at least 30 Amps. The voltage drop across the ground path of resistance would then be:

$$E = IR = (30)(.01)$$
$$\text{Therefore, } E = 0.3 \text{ volts}$$

This voltage is easily measured and the instrument may be calibrated in terms of Amps, that is, 0.1 volts would indicate a current of 10 Amps.

If the normal charging rate is, for example, 10 Amps, the voltage measured would be 0.1 volts. From this example, it is clearly evident that there is plenty of voltage available for a sensitive indicator and can be used to our advantage in a charge indicating instrument without adding additional shunt resistance into the electrical system. Our next problem is to determine how and where to connect the meter in the circuit.

Basic Ammeter Circuit

Fig. 6 shows the actual circuit used in my car with a 50 uA meter. This instrument, as with most instruments (even the very inexpensive tuning indicator instruments) can be converted to a zero center scale instrument so that my meter now has become a ±25 uA meter. I also installed a meter protector circuit across the terminals to limit the current during starting, and added a 2k

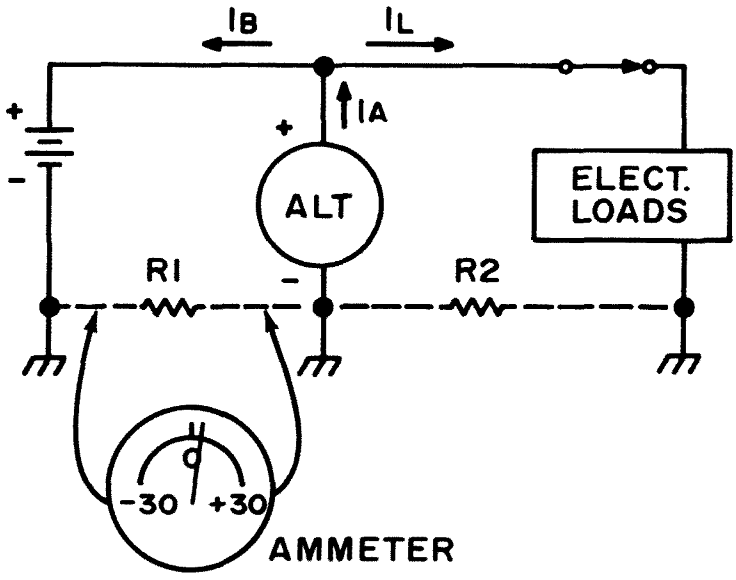

Fig. 5. Typical operating condition with battery charging current tapering off.

resistor into the circuit to allow for calibration of the meter.

As I mentioned, the basic movement that I used was a 0-50 uA meter manufactured by Midland, Model No. 23-206. However, any meter may be used, possibly up to a 0-1 mA meter, depending on your own particular situation. You may want to use a VOM to check your particular ground path circuit under normal conditions to find out how sensitive a meter movement will be required in your particular case. After this has been determined and you have a meter available,

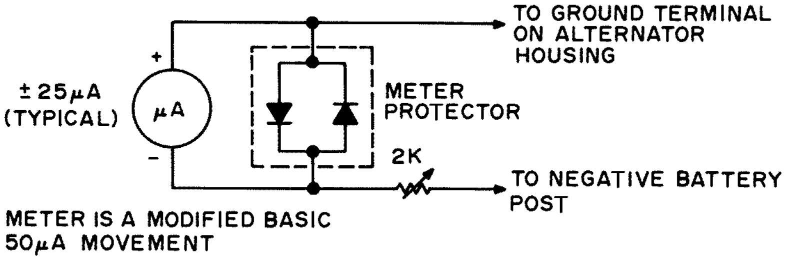

Fig. 6. Actual diagram for adding an ammeter to car electrical system — no changes are required to existing wiring.

the next step is to carefully remove the plastic cover on the meter. Then, after removing the two retaining screws of the dial, it must be carefully slipped out from under the pointer. Then, all that is necessary is to erase the lettering not required and to add in new lettering according to your own particular circumstances.

The next step is to convert the instrument to a zero center scale type instrument. This is easily accomplished by moving the zero adjustment until the pointer is at mid-scale. It is possible to do this on all instruments that I have seen, including the little horizontal movements that are available through surplus outlets for a dollar and a half. The quality of the instrument is governed only by your own particular needs. The final step is to replace the dial and plastic cover and install the protective diodes across the meter terminals along with the multiplier resistor used for calibration.

Installation Details

The next step involves installation in the car and connecting the meter leads to the proper points in the electrical system. It is best to use solid conductor wire of approximately 18 gauge, and if you can find Teflon-coated conductors, so much the better. Since the leads will be near hot parts of the engine, Teflon-insulated conductors are more resistant to heat and grease in this type environment. The two leads from the instrument circuit should be routed through any available opening in the fire wall and around to the alternator and negative terminal of the battery. One conductor is connected to the ground terminal on the alternator housing. The other conductor is connected to the negative battery terminal right at the battery post. To check to see if you have the right polarity, leave the engine off and turn on some load such as headlights or press on the brake pedal. The instrument should swing from the zero center scale to the left indicating a discharge condition. If it swings the other way, the leads should be reversed. The next step is to get a rough calibration on the instrument. Turn on headlights or some other load with a known Amp rating and roughly calibrate the instrument based on this amount of load. If you have another ammeter, you can use it to check and calibrate your new instrument.

It is imperative to connect the ammeter circuit into ground path R1 between the battery negative terminal and the alternator ground terminal. Otherwise, if by mistake it is connected between the battery negative terminal and ground near some of the electrical loads, it is easy to see from the basic diagrams above that you would get roughly twice the indication on discharge which is the sum of the voltage drops across R1 and R2 in a discharge condition. In a charge condition, the indication will be the difference between the voltage drops across R1 and R2 since the voltage drops are in opposite directions. This obviously will give you false indications and will be useless as far as determining the state of charge of your battery.

Conclusion and Results

You are probably wondering at this point as to whether or not it would have been easier to buy one of the commercially available ammeters for six to ten dollars and not have the problem of converting another meter for use in this project. It is true it may have been easier, but the meter movement in commercial automotive instruments is not known for its quality and there are usually no means of calibrating the commercial instrument. Also, most commercially available instruments make use of an additional meter shunt into an electrical system of approximately ¼ Ohm. Admittedly, this is not very much resistance to add into a circuit, but a quarter Ohm at 20 Amps could introduce an additional voltage drop into the automobile electrical system.

My particular charge indicator has been in operation for some time, and it has been a great help to me in monitoring my automobile electrical system. Since many amateurs have mobile equipment added into their cars, I hope this article will be of benefit to them in keeping their equipment in top operating condition. ■

Really Soup Up Your 2m Receiver

by
Calvin Sondgeroth W9ZTK
800 Fifth Avenue
Mendota IL 61342

Using semiconductors now available for VHF service it is possible to build a preamplifier for 144 MHz that will perform as well or better than all but the best vacuum tube designs in terms of gain and noise figure. The solid state approach offers several advantages over a vacuum tube amplifier in size and power requirements. The preamp described is completely self contained and can be powered for many hours by a small transistor radio battery. In addition, semiconductor prices are now about one fourth the cost of a new vacuum tube for the same job. The money saved by using the transistor can be well spent on a couple of good quality components for the rest of the circuit.

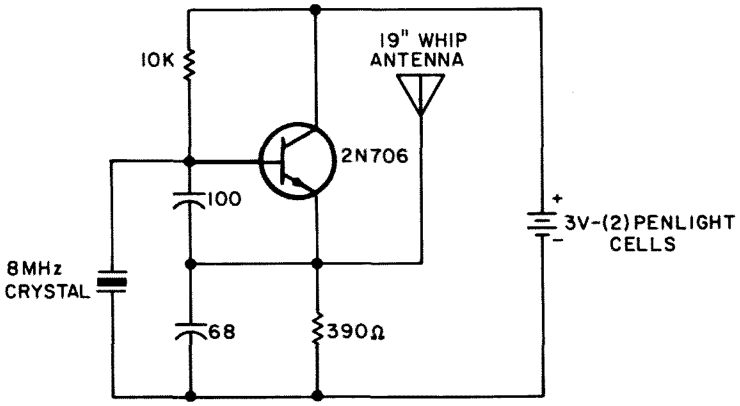

Fig. 1. 144 MHz weak signal source.

Circuit Description

The circuit for the preamp is shown in the schematic diagram. Q1 is operated in a grounded base configuration for best stability at 144 MHz. The input impedance of this type of amplifier is quite low and the emitter is tapped down well toward the ground end of the input coil L1 compared to the tap position that might be used in a tube amplifier. The emitter is raised above ground by R2. A choke in the emitter lead with R2 bypassed for rf was tried, but the amplifier seemed to work as well with R2 alone, so the choke was abandoned. The input and output coils L1 and L2 are identical except for the second tap on L1. They are wound with #18 bus wire with 4½ turns spaced out to ½" long. Both input and output tanks are tuned to resonance with piston type trimmer capacitors. Here is where the money saved on buying a new 417A tube or its equivalent can be put to good use. The price difference between the tube and transistor will just about pay for two good quality capacitors. The piston tuning action makes circuit adjustment very smooth.

The bias operating point for the amplifier is set by the voltage divider R1 and R3; the value of R1 is adjusted for optimum gain versus noise figure as described later.

Construction

A pictorial drawing of the mechanical layout of the amplifier is shown. A standard

1-5/8" X 2-1/8" X 3-1/4" minibox serves as a shielded enclosure for the finished unit. Q1 and its associated components are mounted on a piece of 1/16" thick copper clad circuit board material that just fits inside the box with clearance at the sides for the cover. The transistor is mounted through a 3/16" hole in the center of the board with a second piece of circuit board material soldered vertically across it to act as a shield between the input and output circuits. The shield has to be notched to clear the transistor leads with the emitter and base leads on the input side and the collector and the fourth lead connected to the transistor case on the output side. The case lead is soldered directly to the ground copper on the center shield.

Two 500 pF feedthrough capacitors serve as the points for the base and the B+ leads; two insulated terminals are used for the emitter and collector connections. The bias resistors R1 and R3 are mounted on top of the board as shown for ease in adjusting their values. The emitter resistor R2 could probably be on top as well, but I thought it best to keep it down inside the shielded input compartment since it is above rf ground. The piston trimmers are located approximately as shown with the coils connected to them as indicated on the schematic. This general layout makes for the short leads important in VHF wiring. Ground connections are soldered directly to the copper on the circuit board.

After the circuit is wired up on the board it is mounted inside the minibox as shown with two standoffs and screws in diagonal corners. Two dummy screws in the other corners act as feet to match the screws going through the standoffs. The four resulting studs can be used for mounting to another chassis if desired. The input and output connectors J1 and J2 are mounted on the ends of the box. The output end has a 500 pF feedthrough capacitor and a ground terminal for connection to an external battery.

Adjustment and Tune-up

For preliminary adjustment of the preamplifier, connect a 5000 to 10,000Ω potentiometer in the circuit in place of R1. Tuning is done on a weak signal. If your location is like mine there will either be no signals at all or those present will be weak, so for extended periods of adjustment a local signal source is desirable. A grid dip meter can be used, but the stability of a crystal oscillator like the one shown is much better. Its harmonic in the 2 meter band is fairly strong and the signal source can be removed from the receiver location until the signal is just readable without the preamp ahead of the receiver so that improvements with the preamp connected can be noted.

With the amplifier in the line and the bias adjust pot approximately in the center of its range, the weak signal is tuned in and C1 and C2 are adjusted for maximum signal. With the tanks peaked, adjust the bias pot for best improvement in signal over the noise output of the receiver. Remember that what we are looking for is best margin of signal over the noise and not maximum S-meter or other output meter indication. In general a bias point where the noise output of the receiver just starts to increase is optimum. Increasing the voltage at the base of Q1 too much beyond this point increases the noise output of the amplifier, and a point is reached at which the increase in gain obtained is not enough to make up for the poorer noise figure of the system.

When the pot has been set for optimum performance its value is measured and replaced by a suitable fixed resistor. Values from 2000–4000Ω can be expected with the 2N2708 specified. Two holes are added to the minibox cover for access to C1 and C2 since putting on the cover detunes the input and output circuits slightly and they must be retuned with the cover in place.

Conclusions

The transistor specified was used because it was available. It is rated up to 200 MHz with a gain of 15 dB and costs a little under $3.00. Other RCA transistors in the same family should work just as well. For example, the 2N4936 is rated at 20 dB gain up to 450 MHz and is even less expensive than the 2N2708.

For simplicity, and improvement in two meter work, this kind of device is hard to beat . . .

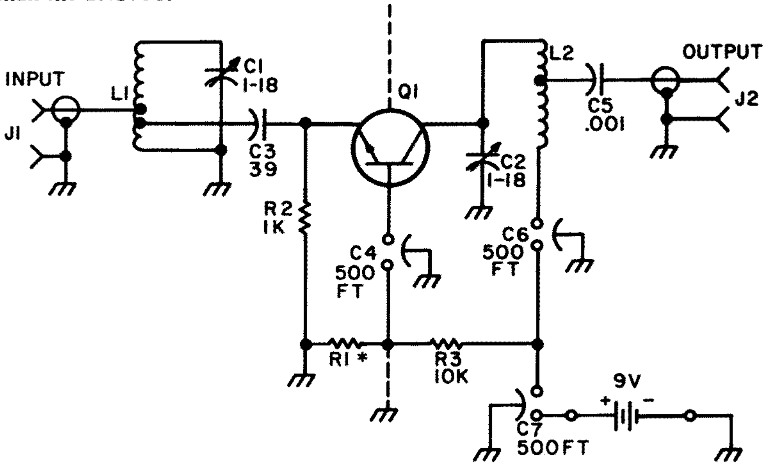

*Fig. 2. L1 – 4½ turns #18 3/8" diam x ½" long; tap at 1 turn for emitter; tap at 1½ turns for input. L2 – 4½ turns #18 3/8" diam x ½" long; tap at 1½ turns from B+ end. Q1 – Ep. F1. NPN silicon transistor, 2N2708. C1, C2 – piston trimmers. J1, J2 – BNC coax connectors. *Adjust R1 for optimum gain vs. noise figure.*

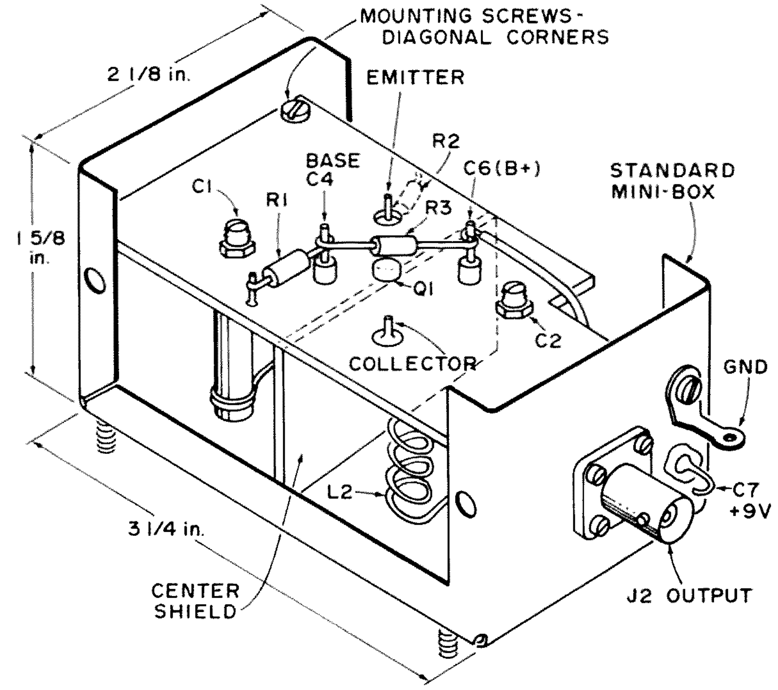

Fig. 3.

The preamp should help out considerably when used ahead of a poor receiving setup on two meters. It will not do much ahead of a good low noise converter since the noise figure of the preamp will degrade the overall performance of the system. When tried on a W2AZL 417A converter all it did was make the S-meter readings higher; reception on weak signals was about the same with or without the preamp. However, ahead of the "twoer" or other marginal two meter receiver, the preamp adds the gain needed for copying weak signals.

No trouble with instability was encountered, although with very high stage gain the circuit can start to oscillate. With a bias setting this high, the noise output of the amplifier makes it practically useless; at normal operating bias as adjusted above the circuit is quite tame. The isolation between input and output is very good since the circuits are effectively in separate enclosures formed by the minibox, the circuit board and center shield.

For simplicity and improvement in two meter work, this kind of device is hard to beat. With a few parts and a spare evening, it can be put together and tried ahead of the receiver with a minimum of metal work and chassis drilling. And the best part comes when the battery can be used instead of digging into the receiver or another power supply. ■

How's Your Speech Quality?

73 Magazine Staff

The objective of speech processing has always been to obtain more "talk power" from a given transmitter. In the case of SSB, this has meant increasing the average to peak ratio of the af (and hence eventual rf) waveform.

In FM systems, it has meant limiting the maximum allowable deviation to not exceed the receiver passband. Compressors, clippers or combinations of the two methods are used to accomplish the desired effect.

One problem that often arises with simpler circuits is that an increased bassiness appears in the processed speech the more it is processed. The reason for this may not be apparent when one looks at the so-called frequency response of a compressor or clipper circuit as shown in Fig. 1.

The problem arises because the frequency response of the compressor or clipper circuit will change depending upon the input level. The response of Fig. 1 is plotted before any compressor or clipping action becomes effective and looks classically effective.

The low frequencies which contain most of the speech power but little of speech intelligibility are reduced in value and a gradual rising response to about 3 kHz gives emphasis to the higher frequencies which provide a "presence" effect in the speech.

If one plots the frequency response for different values of compressor or clipper action, as shown in Fig. 2, it will be seen that as the amount of compression or clipping increases, both the low and high frequency response of the output is extended.

The compressor/clipper action in most such circuits, which are not frequency selective, simply levels out the whole output over the entire speech frequency range. The harder one "hits" the compressor/clipper, the more pronounced is the effect. So, one can often not achieve the maximum value from such a circuit and ends up with a compromise setting of the circuit. This provides some increase in talk power without too much speech degradation.

Another problem also enters the picture – the problem of distortion due to the generation of intermodulation and harmonic

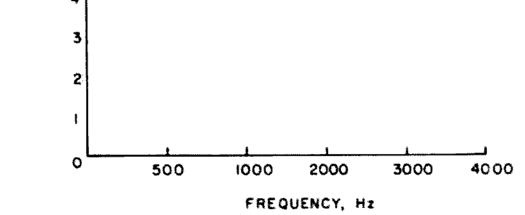

Fig. 1. (Black) Typical tailored voice frequency response of a speech processing unit at very low input levels.

Fig. 2. (Grey) The output level of a speech processor as the circuit is adjusted to clamp the output at different levels. Notice that as the output level is more severely clamped the overall frequency response becomes broad and flat.

products in the compressor/clipper circuitry the harder it is driven.

The latter problem will occur first in some compressor circuits and would tend to indicate that the input stages are not designed with a great enough dynamic range.

Sophisticated, and costly, compressor/clipper units get around some of these problems by splitting the frequency band to be processed into different ranges, applying a weighted processing to each range and other techniques. Broadcast quality, after all, just doesn't mean an ultra smooth frequency response but keeping that transmitter modulated within FCC specs just as heavily as possible.

Compare a recording of a good AM or FM talk station with that obtainable from any amateur speech processing unit. If the recording is made such that the peak input level to the recorder is the same in both cases, the tremendous difference in effectiveness of the commercial unit is apparent.

The point here is not to criticize amateur circuits since commercial units cost thousands of dollars and are part of an engineered microphone-to-modulator chain, but to indicate that much still remains to be done in the amateur sphere.

One improvement that can be made in most simple compressor/clipper circuits is to correct the frequency response to get away from the problem previously described.

Two methods are possible – either a dynamic circuit that will correct the input frequency response according to the amount of compression or clipping, or a static filtering circuit both before and after the compressor/clipper circuitry.

The author has experimented with active circuits using FETs as variable resistance elements in a 2 stage RC high-pass filter arrangement placed before the input to a compressor. The control voltage developed in the compressor was also used to control the FETs and in such a manner that the greater the control voltage developed (due to greater input levels), the frequency slope of the high-pass filter was changed to attenuate the lower frequencies more and more.

The circuit did work but every component had to be tailored to work with a particular compressor circuit. Therefore, since it is far from a universal approach the circuit details are not presented here.

A more universal approach involves the use of passive components to form a suitable filter both before and after a clipper or compressor circuit. The details of such filters are shown in Fig. 3 for typical low impedance input and output circuits. Standard handbook formulas can be used to design the filters for any desired combination of impedance levels.

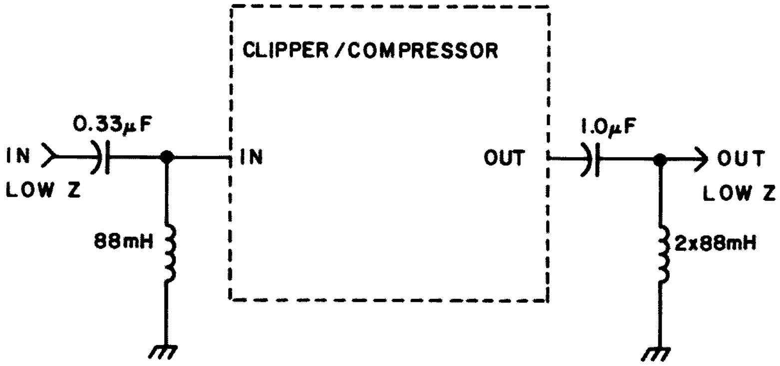

Fig. 3. Some typical circuit values for the filters discussed in the text.

The input filter performs a pre-emphasis function to reduce the low frequency to drastically reduce the low frequency components. It has a cutoff frequency of 800-1000 cycles.

The main purpose of this filter in reducing the low frequency input to a compressor or clipper is to reduce the inter-modulation products caused by the low frequencies, and which remain within the speech passband up to about 4 kHz. This will allow a greater degree of compression or clipping to be used. The output filter is a high-pass filter with a cut-off of about .3 kHz in order to provide the low frequency rolloff which is lost when heavy compression or clipping is used. In the case of a clipper, it is assumed that it already contains the necessary low pass filter to reduce the harmonic energy above about 4 kHz.

The filters have only a few dB insertion loss in their passband and so can be used with almost any compressor or clipper circuit which has just a bit of reserve gain. There are no particular construction problems with the filters. Standard surplus toroid telephone coils are highly recommended for the inductor elements and are inexpensive to use.

One might like to experiment with the rolloff frequencies of the filters by varying the capacitor values slightly to suit individual voice characteristics. The use of the filters will definitely enhance the effectiveness of most compressor or clipper circuits. It's accomplished both by allowing a greater degree of compression or clipping and by eliminating the low frequencies at the output of the processed speech which do not contribute to communications effectiveness. The enhancement of a transmitter's effectiveness by such speech filters in conjunction with a compressor or clipper is a matter of subjective evaluation.

Most tests indicate a 2-3 dB improvement. The component costs make this method quite a bargain – and beat raising the transmitter power. ■

A Transmission Line² Matcher

by
Carl C. Drumeller W5JJ
5824 N.W. 58 Street
Warr Acres OK 73122

That title may require some explanation. What it really means is that a length of coaxial rf transmission line is used to effect compatibility between the output impedance of a transmitter and the presented impedance of a transmission line leading to its antenna. Often, you effect such a match by means of an antenna tuning unit. The British call these ATUs. We use a variety of fancy terms, like "Z-matchers," "Transmatchers," "Matchboxes," etc. They all do the same job.

If the mismatch is not extreme, no more than you'd encounter with a VSWR of around 5:1, a section of transmission line can accomplish an acceptable match.

We've all been told many times of the application of a ¼λ section of line for impedance matching. Less often, however, have we heard about the use of other lengths for transforming impedance. That's the purpose of this article.

First, we need to take a look at a graphical representation of the voltage standing wave upon a mismatched transmission. This is often shown in handbooks. A few even hint at the reactances present. These reactances, which vary in both magnitude and sign (inductive or capacitive) as measured along a ½λ section of line, can be put to use. We're going to talk about using them as conjugate reactances, that is, of equal magnitude but opposite sign, to negate undesired reactances on an antenna feedline. Fig. 1 shows the extreme case of a line terminated in a short circuit. Fig. 2 depicts another extreme, a line terminated in an open circuit. Note that these two differ only by 90°. That is, if you were to slide one 90° to a side, it would be the same as the other. From this, you can deduct that *all* other terminations lie somewhere between these two extremes. So they do, regardless of whether they're purely resistive, purely reactive, mixtures of the two (as are most real-life antennas), higher than the characteristic impedance of the line, or lower.

Now, with this as a starter, let's take a look at the average transmitter. In all probability, it was engineered (probably much against the design engineer's better judgment but by the stern orders of the sales department) "to be used with transmission lines with a VSWR of not more than 2:1." This is choice weasel wording to give the manufacturer impunity should an inept user damage it by some gross misuse.

Let's consider why the manufacturer likes to include the weasel wording. Look at Fig. 1. Points A, C and E have an impedance that is purely resistive and very, very low. You couldn't make such a termination accept power. Points B and D also are purely resistive, but their impedance is very high. It's improbable that these could be made to accept power. In Fig. 2 the same comments apply, only with the high and low impedance points flipped over. But Fig. 3 shows a line terminated in a resistor, one higher than the line's characteristic impedance so that there're standing waves present. Not only are points A, B, C, D and E resistive, but there's a resistive component present at any point along the line. This means that you can slice off that line at any point you desire and still feed rf power to your antenna. But, there's a hooker. There always is. This one concerns all points between the lettered points. Anywhere in these regions the line will present a combination of resistive and reactive load.

The introduction of reaction gives the manufacturer more cold chills than do the excursions of impedance magnitudes. You see, within the transmitter there must be provision for transforming whatever complex load shows up at the transmitter's input terminals to a purely resistive load of the proper magnitude to produce the desired load for the active device (vacuum tube, transistor, etc.) in the transmitter. In most of today's transmitters this is done through transformations provided by a pi-network. Now, if you've ever looked at the formulas for computing the values of the L and the two Cs in a pi-net you may have noticed that the formulas apply solely to resistive input and output terminations. If that output looks into a complex load, one having a reactive component, all bets are off!

This doesn't mean that a pi-net (or, much better, a Pi-L net) can't cope with a moderately-reactive load. It can, otherwise there'd be very few present-day transmitters capable of being used! It does mean, however, that the transmitter's combination tuning device and impedance-matching device (for that is what the pi-net really is) has to negate the reactive component of the load by introducing a conjugate reactance.

How's that done? By deliberately detuning the plate tank circuit from what would be resonance were the load resistive. This causes the tank itself to be reactive, and, if the reactance is opposite and equal to that of the load, the vacuum tube (or other active device) still sees a resistive load. Sounds like a handy way of getting around a problem, doesn't it? But, like many other solutions, it introduces its own set of problems! When the plate tank is detuned, the carefully-selected LC combination is upset. That ratio was selected upon the basis of Q, of maximum circulating current that could be tolerated, and of the maximum voltage that could be handled. Detune one way, and you may melt down a marginal-design tank coil. Detune the other way, and you may have a voltage flashover across a marginal-design capacitor. And don't think those components are not of marginal design! That's why the manufacturer has to weasel-word his guarantee! He leaves it up to you to provide the necessary protection that he's too cheap to build into his transmitter.

You don't want to re-engineer the transmitter; there's not room enough in the case to accommodate adequate components, anyway. You're not too enthusiastic about plunking down from one hundred to several hundred dollars for a "Matchbox" or a similar device. You'd just as soon avoid the complexity of building a "transmatch." But there's a simple way out!

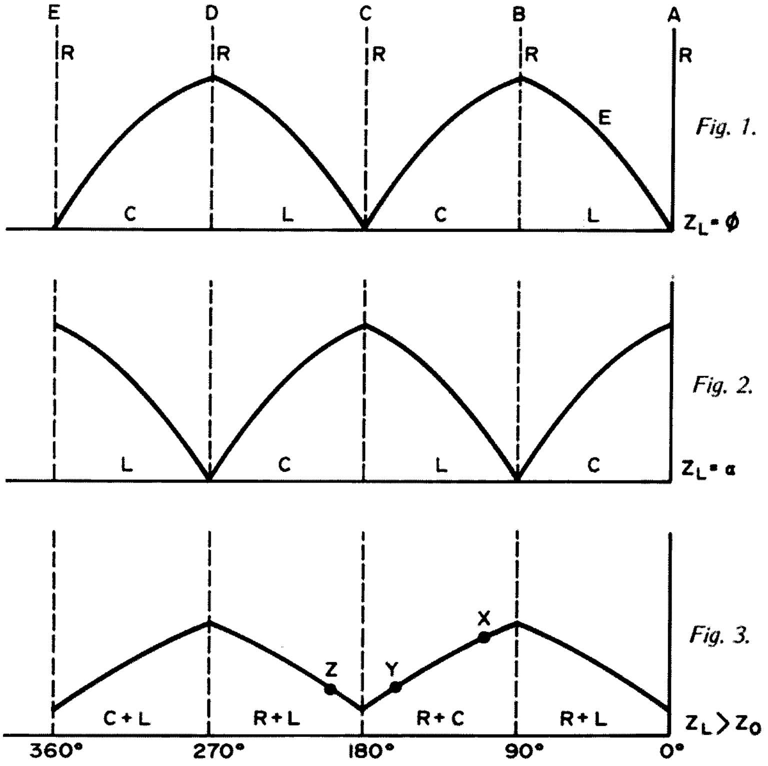

Fig. 1.

Fig. 2.

Fig. 3.

Look again at Fig. 3, and keep in mind that the pattern of those convolutions keeps repeating itself every ½λ, regardless of how long the transmission line may be. Now, suppose your line is of such length that your transmitter is trying to look into it at point X. This high impedance very probably is too much for the transmitter to cope with, but if you were to add just enough line length to patch it out to point Y, the impedance will be lowered to a quite reasonable magnitude! Try it. If your transmitter doesn't like a capacitive load, and some don't, just add enough additional line to patch it out to point Z, which is inductive-plus-resistive.

This sounds like a big job, one that requires a slide rule plus a stack of tables and graphs. Don't believe it! Get a few hunks of transmission line of the same impedance as your feedline, a few coax connectors, and experiment. Use low power (turn down the exciter drive), and you'll not endanger your transmitter. You'll be pleasantly astonished at how easy it is to hit (by a purely hit-or-miss technique) upon a presented impedance with which your transmitter is happy. And a happy transmitter is what you're working toward.

Now for a word about what you're *not* doing. You're not "trimming the transmission line to decrease the VSWR." That is a pure myth. The VSWR is determined solely by the relationship of the line's

characteristic impedance and the load at the far (antenna) end. No amount of fiddling at the receiving end or messing with line length will affect the VSWR. Changing line length will, however, change the impedance the line (if it's mismatched) presents to the transmitter. And that's what you'll be doing.

In my case, I'm using a 3800kHz antenna on 4590kHz. Adding about 3.66m (12') to the only-the-Good-Lord-may-know-what length of my transmission line transformed the impedance to a value easily coped with by an ordinary pi-net output circuit. High VSWR? Undoubtedly! High signal loss? I doubt it, for my reports from distant stations compare with those received when using a resonant antenna.

So go ahead and use a "transmission line[2] matching" device. It's simple, it costs very little, and it does the job well. ■

ASCII to Baudot Converter

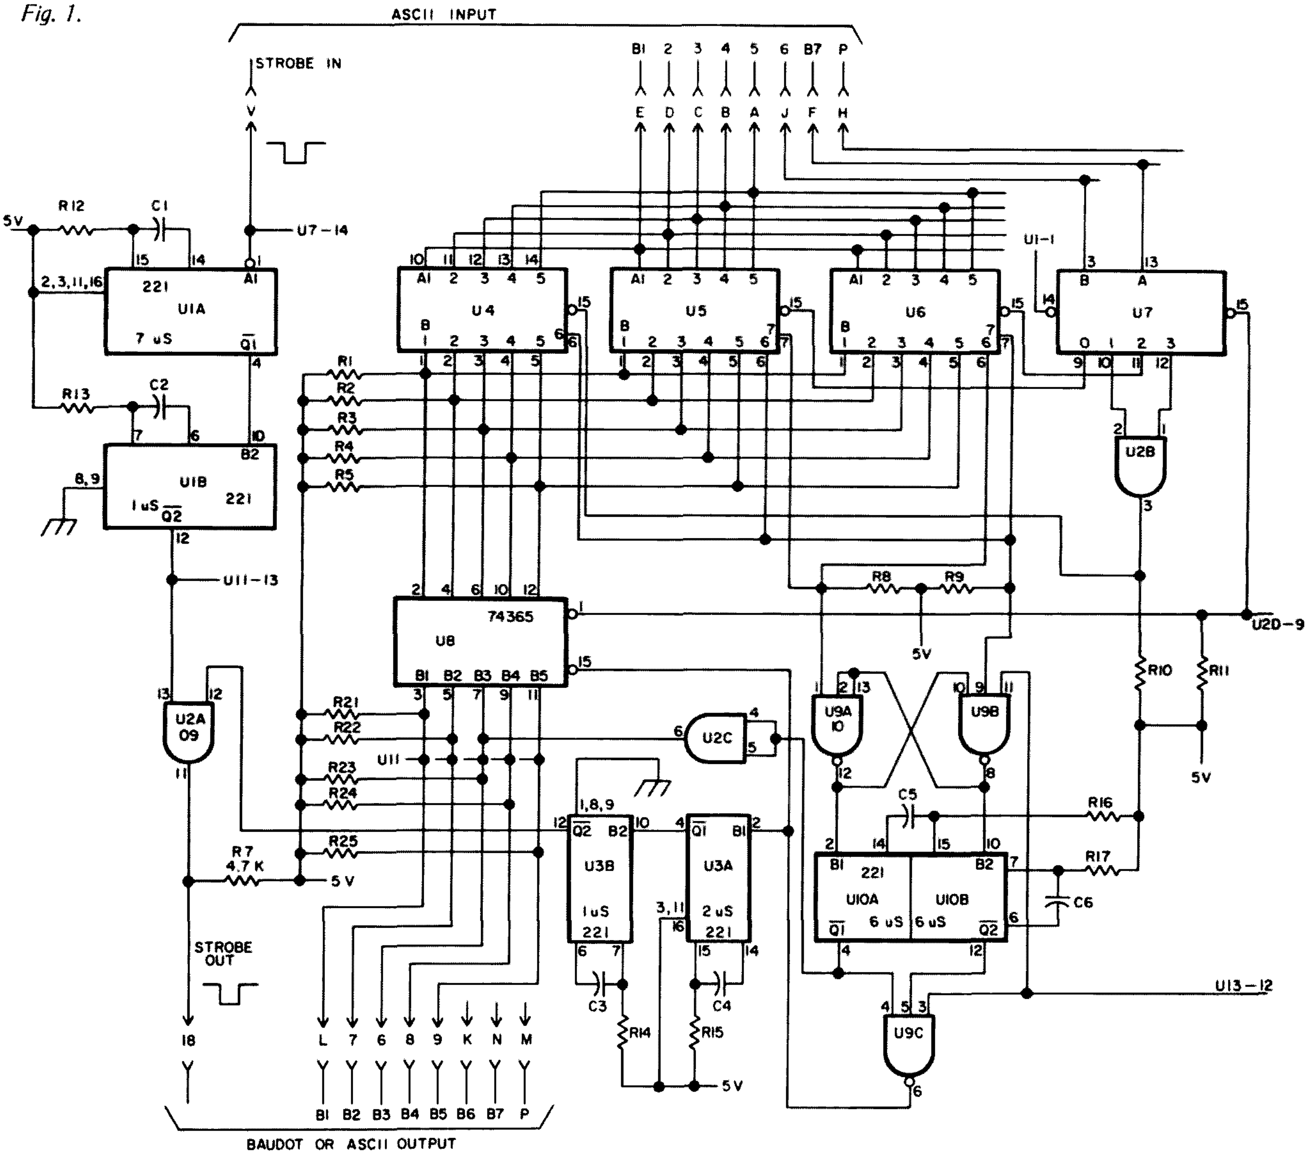
by
Cole Ellsworth W6OXP
10461 Dewey Drive
Garden Grove CA 92640

After acquiring a surplus ASCII encoded keyboard[1] it was desired to use this keyboard on the amateur RTTY frequencies. Under present FCC regulations, only 5-level code is permitted (commonly called Baudot code, but actually a version of the Murray code). Therefore, we needed a conversion device that would change the 8-level ASCII code to 5-level code. There are several different approaches to this problem presently in commercial use. One of the earlier conversion methods utilized tape reperforators and tape readers to accomplish the conversion. The more modern video display communications terminals in some instances use computer memory and software to make the conversion. Some integrated circuit manufacturers have made available commercial versions of custom programmed ROMs which greatly facilitate a bi-directional conversion but seem to be somewhat different in format from my requirements, including low cost.

The ASCII code is capable of generating 128 characters (2^7), of which up to 96 may be printing characters. (The remaining 32 are termed "Control" characters.) The Baudot code is capable of generating only 32 characters (2^5) so a "Case Shift" method is used to provide a second set of 32 characters while maintaining a 5-bit code. Thus the need for FIGS shift and LTRS shift on 5-level machines is apparent. It is the requirement for generation of the case shift character that makes the problem of conversion from ASCII to Baudot so interesting. Conversion in the opposite direction, i.e., from Baudot to ASCII, is relatively simple. Witness the recent publication of a circuit[2] that requires only four ICs to perform the conversion.

I had been mulling around several possible approaches to the conversion problem when two significant situations arose which served to solidify the design approach. The first was during the course of a discussion of the matter with Jerry WB6WPX, when he suggested "jamming" the case shift character into the Baudot output bit stream just ahead of the character requiring the case shift. The second was the development of the UT-4 by Irv W6FFC[3]. The FIFO in the UT-4 makes the perfect buffer for absorption of the case shift character (which is generated within the period of a few microseconds) without

Fig. 1.



significant delay in conversion of the following ASCII character.

An initial cut at the design resulted in a 12-chip circuit with a timing budget that appeared feasible. A second cut at the design resulted in an operational prototype requiring ten chips including the three conversion PROMs. At the suggestions of W6FFC, a circuit was developed to provide automatic generation of a Baudot LETTERS shift character following a LINE FEED. This feature eases generation of proper end-of-line routine when using an ASCII keyboard and is well worth the three additional chips required. The final design uses 15 chips and was dubbed the ASCII to Baudot Converter – version 1 (ABC-1).

The logic diagram of the ABC-1 is illustrated in Fig. 1. Fig. 2 is the converter timing diagram. Interface with the UT-4 is shown in Fig. 3. Note that one additional 7400 chip (IC13) and one switch (S9) must be added to the UT-4 circuitry to provide ABC-1 interface while maintaining full capability of the UT-4 in the originally intended application.

Features

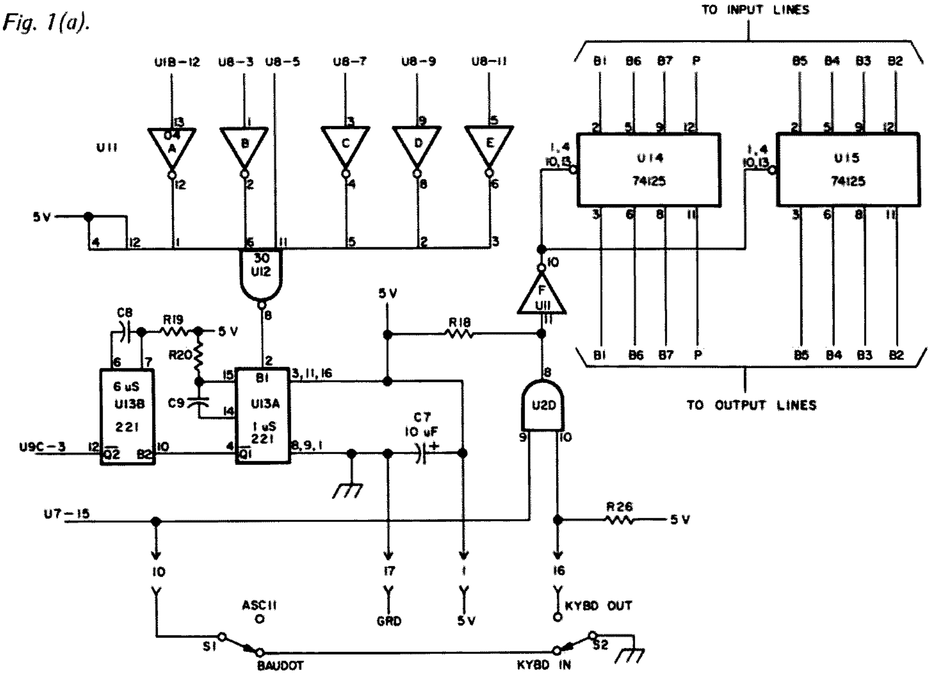
1. Converts all ASCII characters that have Baudot equivalents to the proper Baudot character.

2. Converts all non-equivalent characters to a Baudot BLANK unless otherwise programmed in the appropriate PROM.

3. Converts both upper and lower case ASCII alphabet characters to the equivalent Baudot character.

4. Provides automatic Unshift-on-Space for Baudot machines.

Fig. 1(a).



Figs. 1 and 1(a). U1, 3, 10, 13: 74221. U2: 7409. U4, 5, 6: 8223. U7: 74155. U8: 74365. U9: 7410. U11: 7404. U12: 7430. U14, 15: 74125. R1-5, 7-11, 18, 26: 4.7k. R12: 30k. R13-17, 19, 20: 15k. R21-25: 10k. C1: 330 pF. C2, 3, 9: 100 pF. C4: 210 pF. C5, 6, 8: 560 pF. C7: 10 uF, 10 V. Notes: ASCII inputs B1 through B7 are positive logic (Mark = High level). U4 is alphabet PROM that converts both UC and LC ASCII to Baudot. U5 is control function PROM for Carriage Return, Line Feed, and Bell. U6 PROM converts numerals, punctuation, and space bar. Most ASCII characters with no Baudot equivalent convert to a Baudot BLANK character. U11, 12 and 13 generate a Baudot LTRS shift function immediately following a Baudot LF, thus providing a standard end-of-line routine capability of CR, LF, LTRS. Baudot outputs B1 through B5 are positive logic (Mark = High level). U14 and 15 provide direct ASCII throughput when S1 is in ASCII position. For U1, 3-8, 10 and 13, Vcc is on pin 16 and Gnd is on pin 8. For U2, 9, 12, 14 and 15, Vcc is on pin 14 and Gnd is on pin 7.

5. Provides Automatic Letters Shift after LINE FEED.

6. Provides a Baudot Letters Shift on receipt of ASCII "RUBOUT" or "UNDERSCORE".

7. Provides a Baudot Figures Shift on receipt of ASCII "UP ARROW" or "~".

8. Provides for direct throughput of ASCII code.

9. Provides 3-state buffered data outputs for data bus applications.

10. Easy interface to the UT-4.

Functional Description

Parallel format ASCII data is applied to inputs (address lines) of 8223/74188 PROMs U4, U5 and U6. Note that only bits 1 through 5 are used for addressing the PROMs. Bits 6 and 7 are applied to 2-line to 4-line decoder U7. The binary state of bits 6 and 7 are decoded by U7 to provide an enable signal to pin 15 of the appropriate PROM. Decoding of ASCII bits 6 and 7 is arranged by means of U2B so that both upper and lower case ASCII alphabet will be converted to the equivalent Baudot character.

PROM output data (in Baudot code) bits 1 through 5 from all three chips are "wire-or'd" and applied to 3-state buffer U8. If U8 pins 1 and 15 are both low, data from the selected PROM passes through U8 and appears at the output of the converter.

Simultaneously with the appearance of ASCII data at the inputs of the PROMs, the keyboard strobe signal is applied to U1A. U1A and B provide a total strobe delay of approximately 7 microseconds. At the end of this delay period, the strobe signal appears at the output of U2A. When the ABC-1 is connected to a FIFO such as in the UT-4, the delayed keyboard strobe signal causes a "shift in" signal to be applied to FIFO pin 17. Because the data at the output of ABC-1 chip U8 is already present at the FIFO data inputs, this data is entered into the FIFO as a parallel format Baudot character.

The preceding paragraphs describe what happens in the converter when no case shift is required. Let us say that the character converted in the previous example was the character "R". Let us now assume that the next ASCII character from the keyboard is a period. Conversion of this character to Baudot code requires that it be preceded by a FIGS shift character. The states of bits 6 and 7 in the ASCII period character cause PROM U6 to be selected for punctuation characters (numeral conversion also takes place in this PROM). PROM U6 *output* bits 6 and 7 are Low and High respectively for a period character and are applied to the case shift detector latch U9A,B where pin 12 of U9A was Low for the previous character R. Bit 7 is High and so has no effect on the latch. Bit 6 is Low, causing U9A,B to change state, and pin 12 goes High. This Low to High transition is applied to input B1 of 1-shot U10A, generating a 6-microsecond wide FIGS shift gate at U10A pin 4. This gate performs three functions. It inhibits U8, causing U8 outputs to revert to the 3rd (high impedance) state, and because of the current sources through R21-R25, U8 output bits B1, 2, 4, 5 go High. Bit 3 goes Low because of the inverted (Low) output of U2C which is the second function of the FIGS shift gate. The 3rd function of this gate is to generate a "Case Shift Strobe" pulse by means of U3A,B and U2A. This strobe is delayed 2 microseconds by U3A, permitting the parallel data at U8 output (bits 1, 2, 4, 5 High and bit 3 Low = Baudot FIGS shift) to settle to a static condition before being entered into the FIFO by the strobe signal.

So far, approximately six microseconds have elapsed since the ASCII data and strobe for the ASCII character "period" appeared at the input to the converter. At the end of the 6 microseconds, U8 is enabled, and U2C output returns to a high level. At this time the Baudot character for period (B1, 2 = Low, B3, 4, 5 = High) is present at the output of U8. One microsecond later the delayed (7 microsecond) keyboard strobe from U1B appears at U2A pin 11 and now the Baudot period character is entered into the FIFO. Generation of a LETTERS shift character in U10B is similar to the foregoing except that U2C output remains High (U8 outputs B1 through B5 are all High).

Thus it is apparent that all normally converted characters are delayed by seven microseconds within the converter before being strobed into the FIFO. If a case shift character is required, it is generated and strobed into the FIFO during the seven microsecond delay interval.

U11, 12, 13 and U2D form the "Letters shift after Line Feed" circuit. U11 and U12 detect the presence of a Baudot Line Feed character at the output of U8. The output of U12 goes Low when the normal delayed strobe pulse from U1B appears at U11A. After a one microsecond delay through U13A, U13B generates a six microsecond pulse that is applied through U2D and U9C to start the generation of a Letters shift character as previously described. A non-printing character such as Letters shift, following a line feed, gives the machine time to return to the left margin before printing the next character.

In Fig. 2, waveform 11 of the timing diagram is a composite of the various conditions at the converter output strobe line. The "Typed character strobe" (center pulse in the pulse train) will appear on the strobe line every time a character key is pressed on the keyboard. The case shift strobe and LSAL strobe are shown as dotted lines, indicating they will appear only under certain conditions. Depending on previous conditions, all three strobe pulses can appear in the sequence illustrated when the converter receives an ASCII LINE FEED character.

Construction

The timing components should be kept clear of the trigger inputs on the one-shot multivibrators. Five percent tolerance dipped mica capacitors and five percent ¼ Watt resistors should be used in the one-shot timing circuits. Three ABC-1 converters have

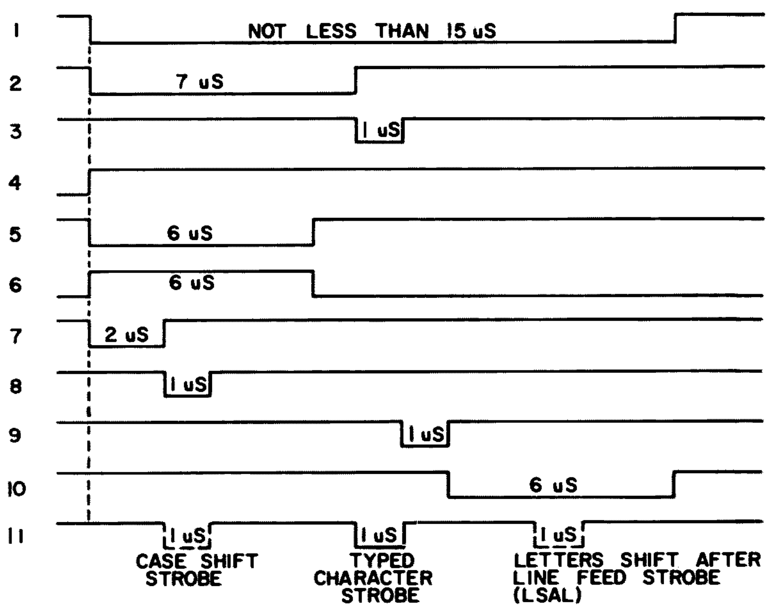


Fig. 2. Timing diagram. 1 — Strobe in, U1A-1. 2 — Strobe delay, U1B-10. 3 — Delayed strobe, U2A-13. 4 — Figs shift, 1-shot U10A-2. 5 — Figs shift gate, U10A-4. 6 — Case shift gate, U10A-4. 7 — Case shift strobe delay, U3A-4. 8 — Case shift strobe, U2A-12. 9 — LSAL gate delay, U13A-4. 10 — LSAL gate, U9C-3. 11 — Strobe output, U2A-11.

been constructed and the timing was well within tolerance using off-the-shelf five percent components.

Use of a printed circuit board makes construction much easier and decreases chances of wiring errors. Even so, the PC board has a high component density and traces are very close together. Great care should be exercised during assembly and soldering to prevent errors in component location, IC orientation, and solder bridges. Sockets or molex pins are recommended for the ICs.

PC Boards and PROMs

EDI[4] has been authorized to make a PC board available for the ABC-1. This is a glass epoxy, double-sided, plated-through hole circuit board. It will fit a standard .156 spring 18-position double-readout edge connector. Boards only, or complete parts kits including the three pre-programmed PROMs, are available.

If you already have a UT-4, Fig. 3 shows the changes required to interface with the ABC-1. If desired, EDI has a modified UT-4 PC board with these changes incorporated. Order "UT-4 IF" PCB/kit. This PCB fits the same type edge connector socket as the ABC-1.

Troubleshooting

Most comments on troubleshooting in the KBI-1 article apply to the ABC-1. The converter is a fairly complex circuit with critical timing parameters. If a scope is not available, it is mandatory that the associated UT-4 be operational in order to check converter operation.

Strobe and data lines from the KBI-1 outputs to the ABC-1 inputs and from the ABC-1 outputs to the UT-4 should be less than 20 inches in length. Transmission line techniques must be used for longer lines as described in the KBI-1 article.

Logic levels at the seven data inputs to the ABC-1 must be stable at the time the keyboard strobe goes Low at U1A-1 and U7-14. As indicated in the timing diagram, the minimum width of the strobe pulse is 15 microseconds. If your keyboard strobe is pulsed with a period, for example, of 5 microseconds, then U14 of the KBI-1 must be used to stretch this 5 microsecond pulse to at least 15 microseconds. Another possible source of improper operation is errors or omissions in the switching and control circuitry (S1, S9) as shown in Fig. 3.

To use the Repeat message function in the UT-4 during operation with the KBI-1/ABC-1, PRELOAD switch S5 is set to PRELOAD, KYBD switch S9 to IN and the message is typed into the UT-4 memory from the keyboard. KYBD switch S9 is then set to OUT and REPEAT switch S8 is set to REPEAT. Then PRELOAD switch S5 is set

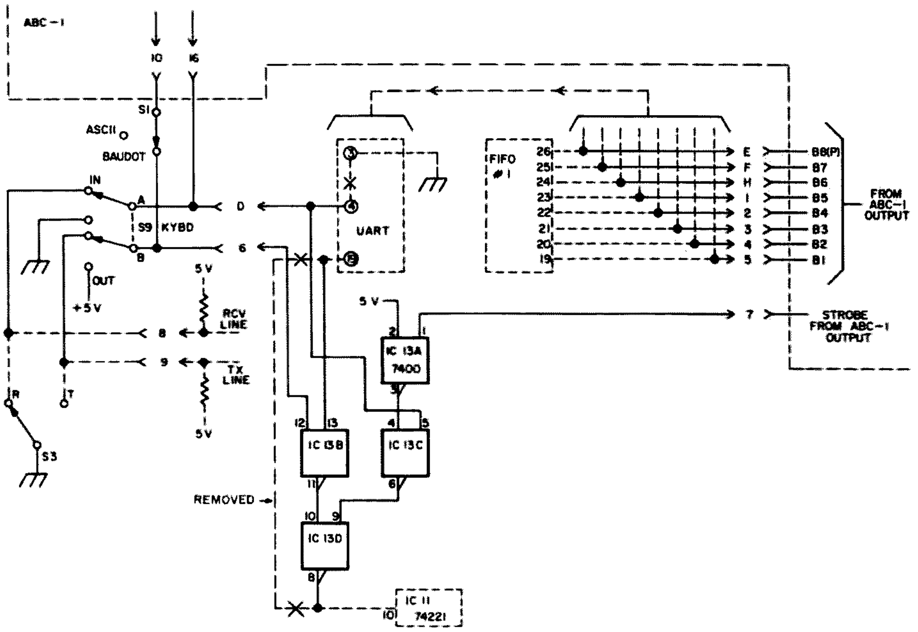

Fig. 3. Changes required to interface UT-4 to ABC-1. Notes: Dotted lines show existing circuits in UT-4. Solid lines indicate added circuitry to accommodate ABC-1. These additions change the UT-4 PCB to UT-4 IF PCB (IF = Interface). ASCII/Baudot switch S1 is the same as S1 in ABC-1 schematic. Keyboard In/Out switch S9 is added to UT-4 control switching. UT-4 IF has all the features of UT-4 except that Space switch S7 is deleted. UT-4 IF edge connector references are for the EDI printed circuit board.

to NORMAL and the message is continuously recirculated through the UT-4. REPEAT switch S8 also permits local copy on your printer during the repeat sequence when using the UT-4 IF circuit board. KYBD switch S9 must be returned to IN if you wish to continue using the keyboard after completing the repeated sequence.

Acknowledgements

In addition to the valuable suggestions contributed by W6FFC and WB6WPX, thanks is due Peter K6SRG, for his many helpful comments and for checking out the first prototype PCB. I am indebted to Steve WA6TVA, for pointing out the need to force the case shift latch to the letters state when auto letters after line feed is generated. Appreciation is also extended to many others who offered suggestions and encouragement, including K2SMN, K3TML, WA5NYY, W6GQC and WA7ARI. ■

No, I'm not going mathematical on you. (At least I don't think so . . .) Instead, I'm going to describe how to construct a device which is guaranteed to warm the heart of any red-blooded gadgeteer – a random music generator. This is a full-fledged construction article, so if you're not interested in warming up your soldering iron (You say you don't even own one? What are you doing in my audience?), you might as well skip this article and go read someone else's. But if you like to sling circuits together, then this little number is definitely for you.

Description

The random music generator (henceforth called the RMG) consists of three basic components: the sequencer, the oscillator, and the waveshaper.[1] As you can see from the basic block diagram in Fig. 1, the sequencer provides control signals to the oscillator and the waveshaper, thus determining the note played and the timbre for it.

The sequencer is a special form of shift register circuit known as a Johnson Counter. It is used to produce (almost) random bit patterns. In the RMG, the sequencer is a 12-bit shift register with an exclusive NOR gate acting as a feedback path. Depending on the exact connection of the feedback gate's programmable input, the sequencer can produce patterns of from 18 to 3255 12-bit words. The sequencer is controlled by a clock circuit, a pulse generator which operates in the range of from 1 to 10 Hertz, approximately.

The oscillator circuit is a voltage controlled square wave generator which will play one of eight musical notes (C, D, E, F, G, A, B, C), depending on the state of the seven note selector lines. The oscillator is

The Sound of Random Numbers

divided down in frequency, by a three stage ripple counter, to provide four octaves of range. Eight potentiometers (R1 through R8) are used to tune each note to pitch.

The waveshaping circuits control the timbre (tonal quality) of the note played, and also the stereo effect. Four "voicings" are available. There was no attempt made to tailor these voicings to sound like traditional musical instruments, so the RMG has a definite "spaced-out" sound to it.

Construction

The electronics for the RMG (Fig. 2) is constructed in three subassemblies: the front panel subassembly (which contains the selection switching and the controls), the power supply subassembly (which can be constructed in the chassis itself), and a 2.5" x 6" piece of tenth-inch-grid perfboard which contains all other circuitry. Wiring is point-to-point, as impedances in the RMG are low and therefore stray coupling is not a factor.

My prototype used a hole matrix switch consisting of 144 holes in a 6 inch square of

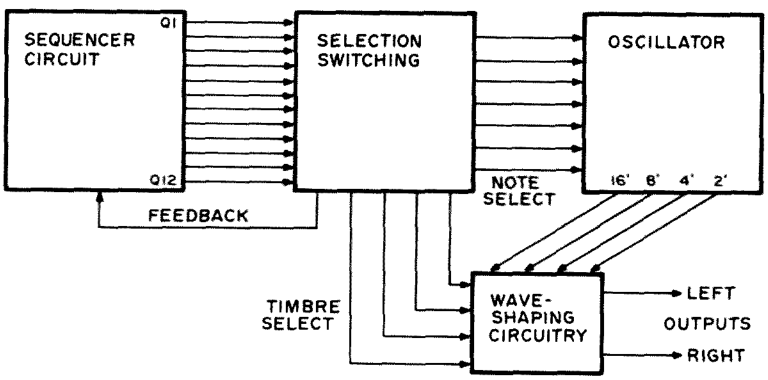

Fig. 1. Block diagram.

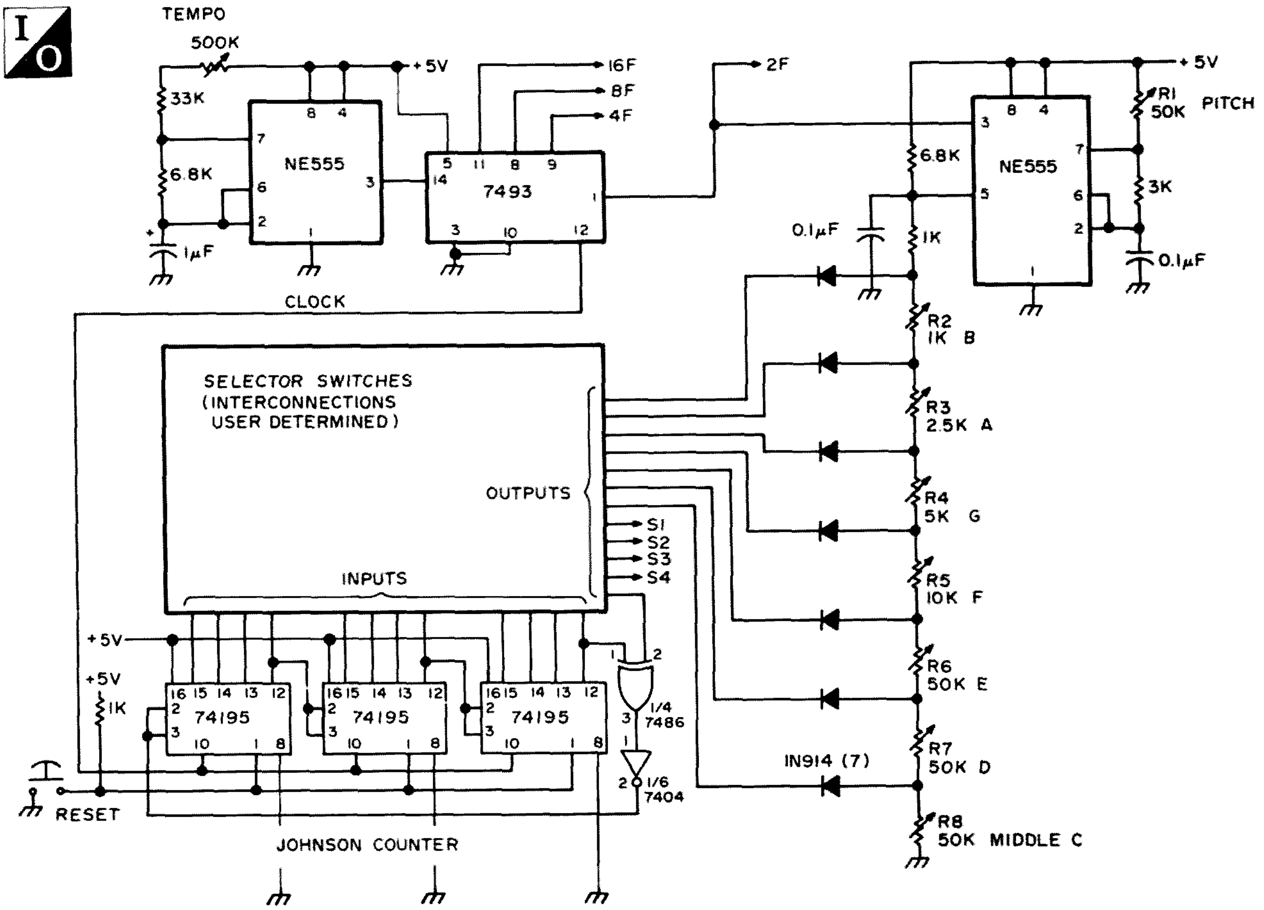

Fig. 2. Schematic.

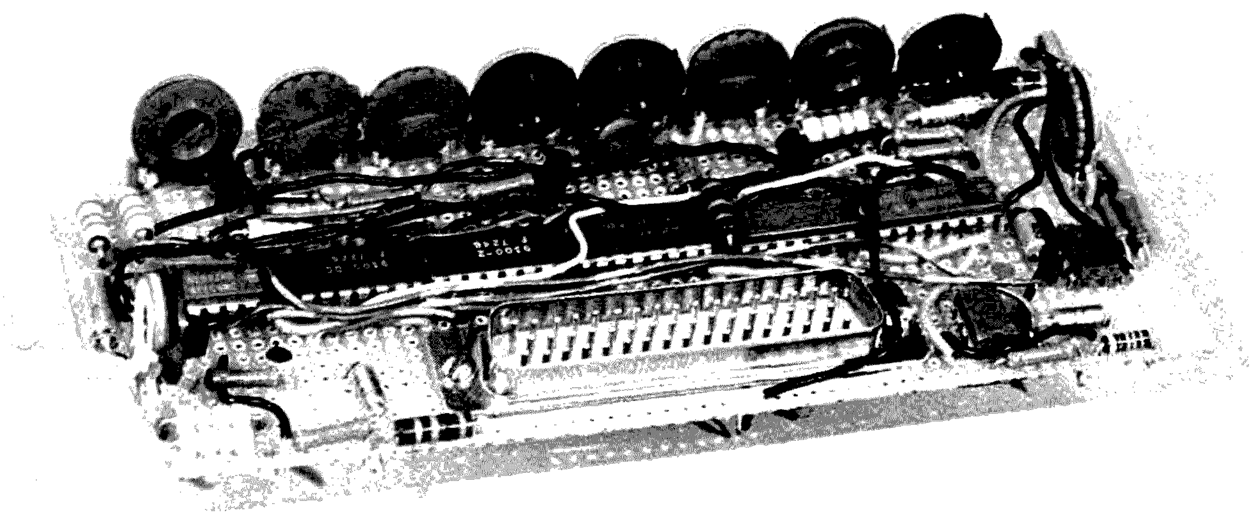
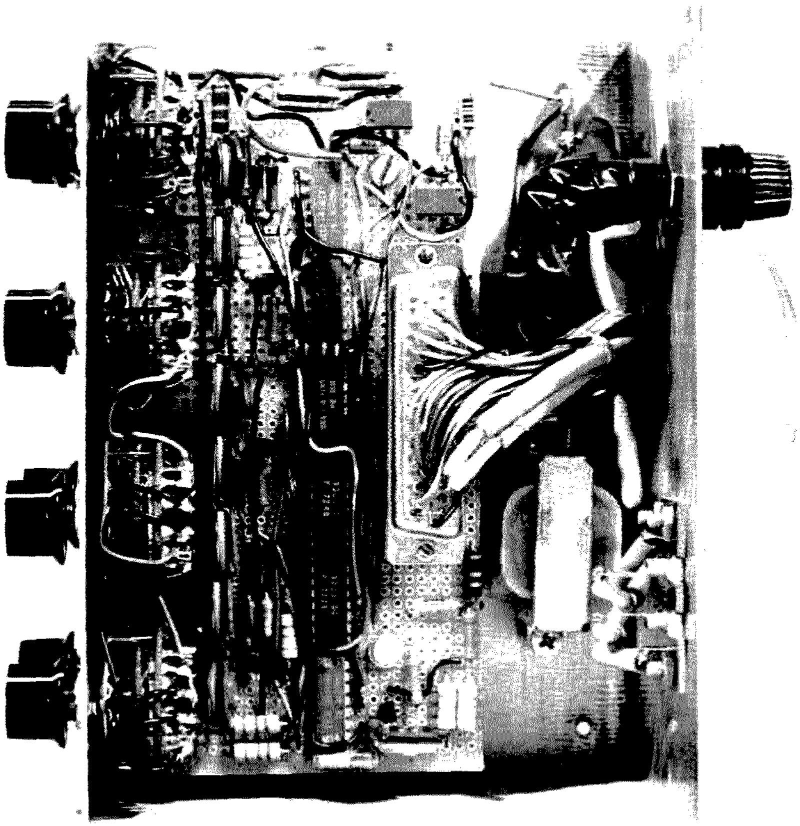
phenolic. Each hole has two contacts in it, which are shorted together when a conductive programming pin is inserted. The main advantage of this scheme is that the pattern of pins in the phenolic gives a quick visual readout of the program set up. The main disadvantages are, first, that one must be careful not to insert two or more pins in the same horizontal line in the matrix switch (as this will short two or more shift register



Closeup of the circuit board. The trimming potentiometers provide adjustment for the pitch of each note and the output level for each channel.



Inside the RMG: The circuit board is mounted on stand-offs and connects to the power supply and front panel wiring via the cable at the rear.

outputs together, and second, that the assembly of such a matrix switch requires that connections to 288 contacts be made in a very small area. One can achieve the same versatility by using twelve single-pole twelve-position rotary switches (at $2.00 each!) with only 156 connections to be made, or by using two twelve terminal barrier strips and some jumper wires. The terminal strips can be mounted on the front panel, or (more esthetically) on the rear of the RMG. A reasonable compromise between versatility and cost can be realized by "hard-wiring" some choices in the selection matrix and using rotary switches to select others, as was done in the version photographed. The mechanical layout of the front panel is, of course, determined by which selection scheme you choose.

The power supply subassembly can be constructed on a terminal strip, with the exception of the LM-309K, which should be mounted on the chassis itself for heat sinking purposes. This is simplified by the fact that the "309" is so constructed as to make the device's case a ground terminal – thus no insulation is required when mounting it to the chassis. A half amp fuse is recommended for safety.

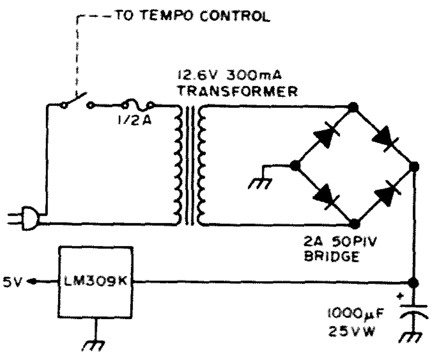


Fig. 3. Power supply. Unless otherwise noted, resistors are ¼ Watt and capacitors are 10 WV.

Q4	28
Q5	819
Q6	18
Q7	819
Q8	28
Q9	45
Q10	126
Q11	3255
Q12	not possible

The audio outputs are terminated in jacks which match the cables of the hi-fi you intend to use with the RMG. My prototype used RCA phono jacks. The outputs are low impedance (approximately 1000 Ohms) high level (about 1 volt peak-to-peak), so use compatible hi-fi inputs for best results.

Tuning

Tuning the RMG should be done with care, as the "listenability" of the instrument suffers if it continuously plays sour notes. A pitch pipe or a musical instrument known to be in tune may be used as a reference. Unless you have a frequency counter which reads to .01 Hz (a rare bird indeed!), you must use a zero-beat tuning method. A counter which reads to 1 Hz is not accurate enough for tuning. To tune the instrument, hold the reset button in and program one note at a time to any shift register output. Start with the highest note (C above middle C) and descend the musical scale, adjusting R1 through R8 for zero beat with the reference instrument.

Table 1 gives the frequencies of the eight musical notes. You may tune to scientific or concert pitch, as you please.

Programming

Programming the RMG is mostly a matter of taste. However, a couple of points can be made. First, very short sequences tend to become monotonous very quickly, but very long sequences can become so involved with permutations as to be hard to follow. Second, if you wish to listen to a sequence, pick a long one; if you play an instrument and wish to improvise around a sequence that the RMG plays, pick a short one.

Table 2 indicates the number of 12-bit "words" produced by the RMG for each sequence it is possible to program.[2] ■

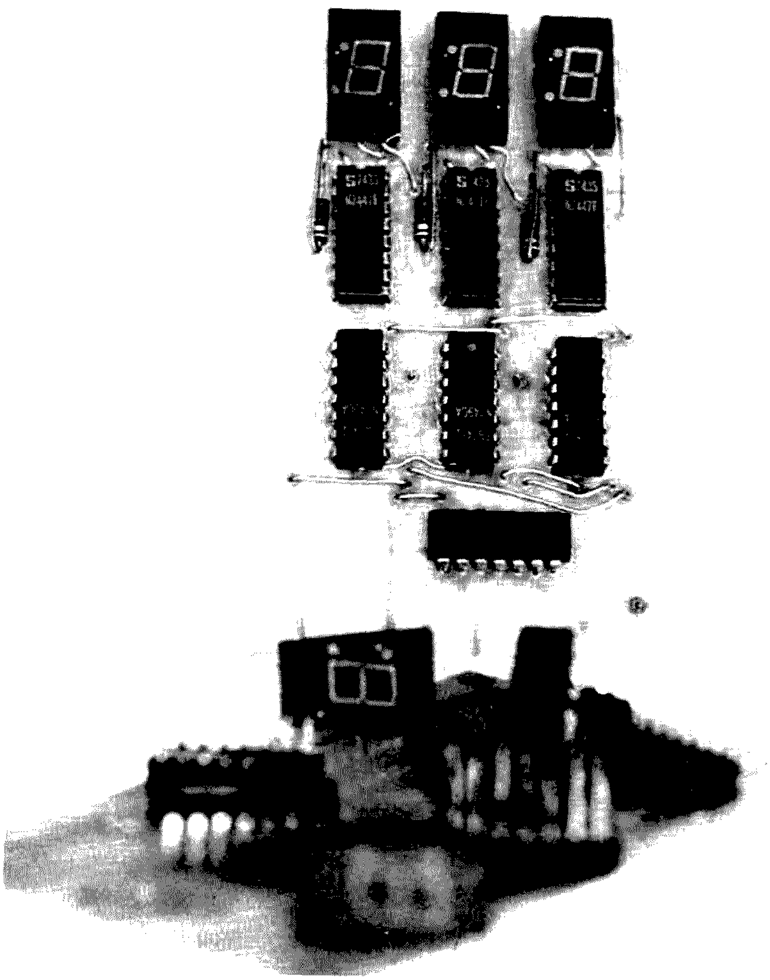
What Do You Want To Count?

by
Jim Huffman WA7SCB
PO Box 357
Provo UT 84601

This is a digital world we live in today. Digital readouts are flashing on everything from FM tuners and wristwatches to "meter-less" VU meters. Ham equipment is going digital, too. Readouts are more accurate, readings are easier to interpret, and



All the 3 DCU parts mount on one circuit board.

bent pointers, non-linear dials, and other mechanical problems are eliminated. New, nearly burnout-proof LED readouts with no parallax and ±1 digit accuracy are becoming available at a price that is allowing more and more workbenches to be fitted up with flashing lights where once stood taught-band, multi-scale meters. Since all this digital equipment is obviously here to stay, this article gives you the basics, so you can understand how that new DVM or digital wristwatch works. And, if you already have the savvy on the digital scene, you'll be interested in the 3 DCU. It's three digits of Decimal Counting Unit. It makes a great counter display, DVM display, etc. And you get three digits for what you would expect to pay for only two digits – less than $18.00!

Digital devices are simple, and most operate on the same very simple principles. Digits are counts, and there are any number of counting systems. The most familiar system is based on counting with the ten fingers ("digit" is derived from the Latin word for finger). Since there are ten fingers the system is called decimal (deci = 10). You could use base 20 (fingers and toes) or anything between. Of course, if you use decimal numbers to represent the figures in another system you will have to use some additional symbols, because there are only ten numbers. The hexadecimal system (base 16) uses letters and numbers. A hexadecimal count goes 0, 1, 2, 3 and so on to 9. For 10 and higher you substitute ABCs, like this: 7, 8, 9, A, B, C, D, E, F. Therefore, a hexadecimal C is the same as a decimal 12. Because of the vast number of digital systems, there had to be a place to start in electronic digital equipment and that was two. Simply "on" and "off." The binary system is a "base two" counting system (bi for 2). While being able to make only a maximum count of two might seem like a shortcoming, it is no problem for an electronic circuit to switch on and off a million times a second. That's pretty fast counting!

Okay, so we use binary, count some pulses, then show 'em to the operator. The problem is, it's tricky for a mere human to see those digits flash past a million times per second. The logical answer: Store the count. This is where the binary counter comes into action. We feed it a group of microsecond pulses and then take some time to look at how many pulses were there. The binary counter operates on both the principle of frequency division and storage.

The basic circuit that makes up a counter is the flip flop. A flip flop does just that. First it flips, then it flops. With a little pulse steering it "flips" on a negative pulse in, then "flops" on the next negative pulse. A

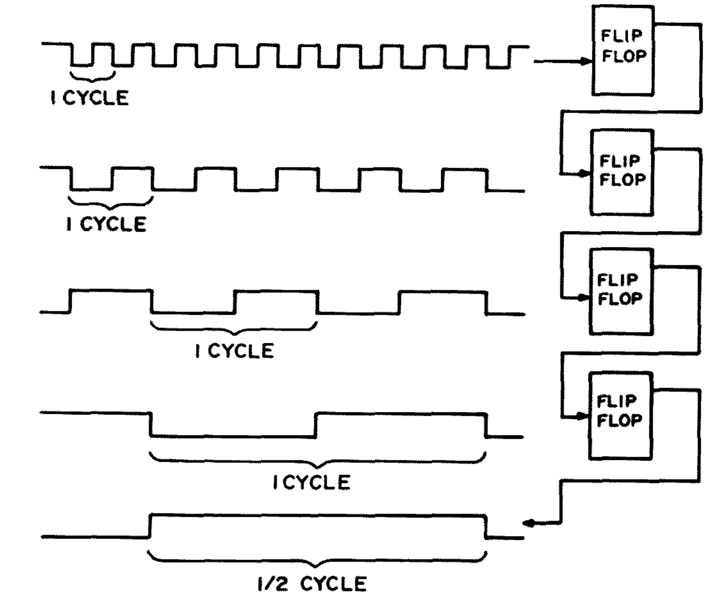


Fig. 1. Flip flops divide frequency.

square wave input has a negative transition every cycle (Fig. 1). It takes two of these negative transitions, or two cycles, to get a flip flop back to the way it started. Thus,

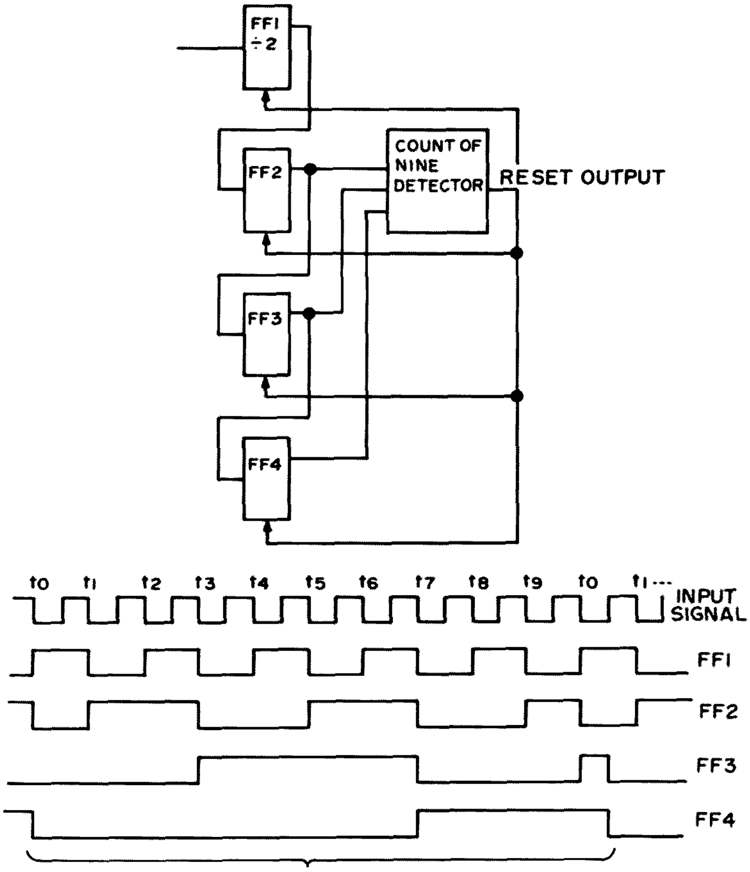

Fig. 2. Counter modified to divide by ten.

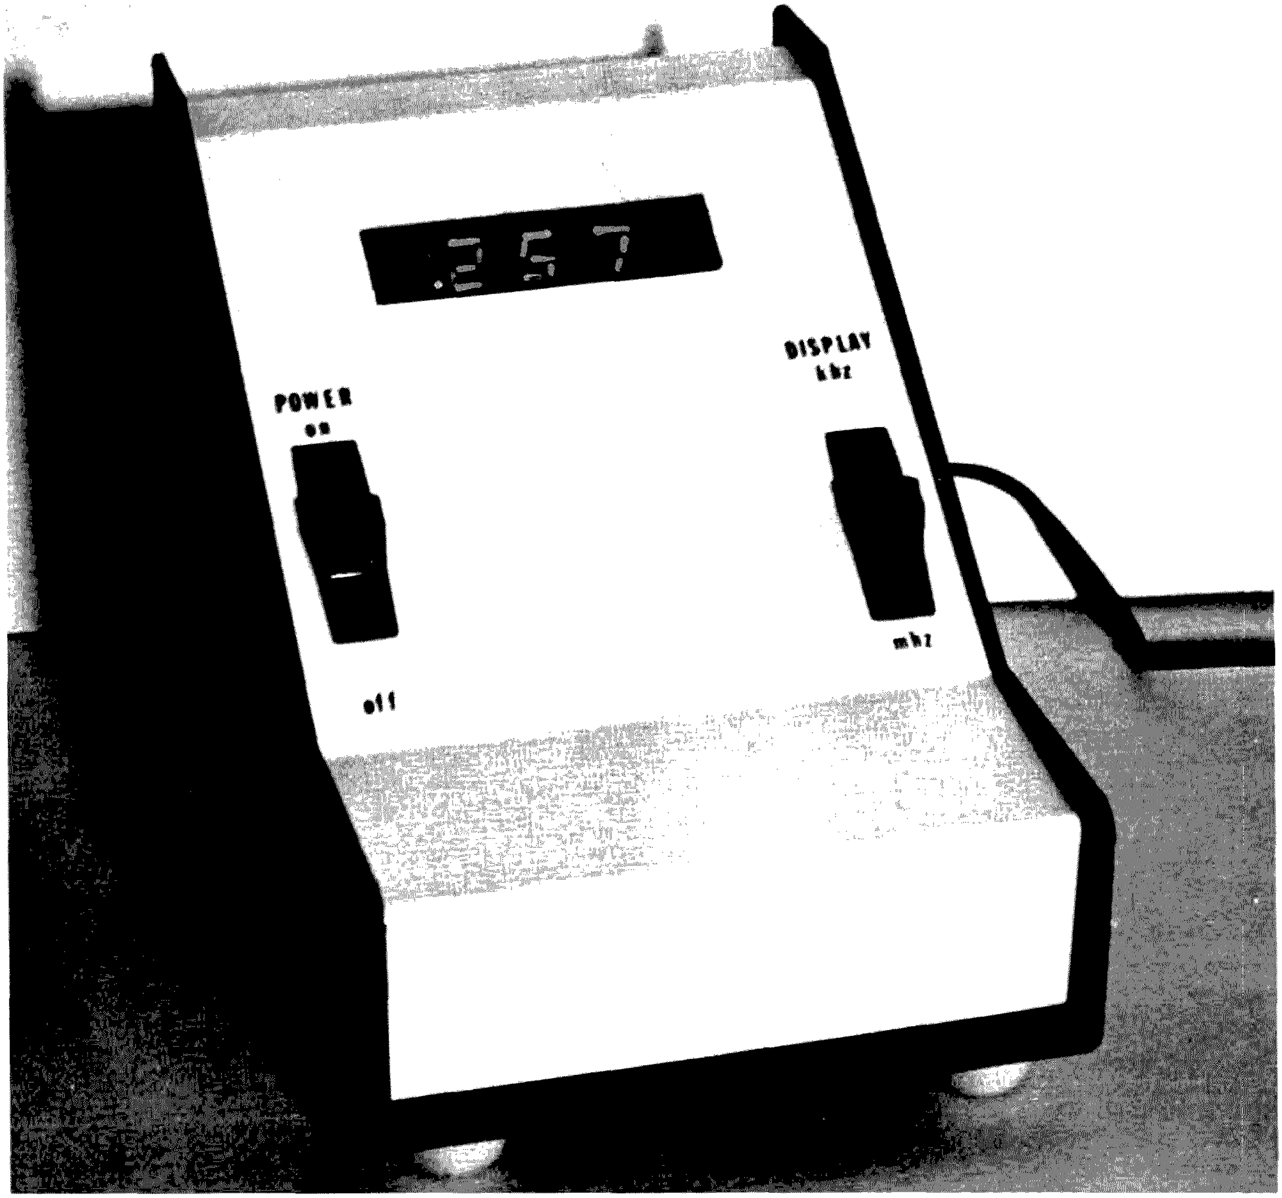

Put a 3 DCU in a cabinet with a timing circuit board, and you have an instant 3-digit counter, great for reading out the frequency of your rig.

the flip flop divides the input frequency by two. If the output of that flip flop is divided by two by another flip flop, we have a simple divide-by-four counter. One more stage yields divide by eight. The number of stages is the same as the power of 2. For instance, the 3-stage counter yields 2^3 or divide by 8. A 2-stage counter (2^2) gives a four count. It is also possible to make the counter short itself by a count to allow counting to any base.

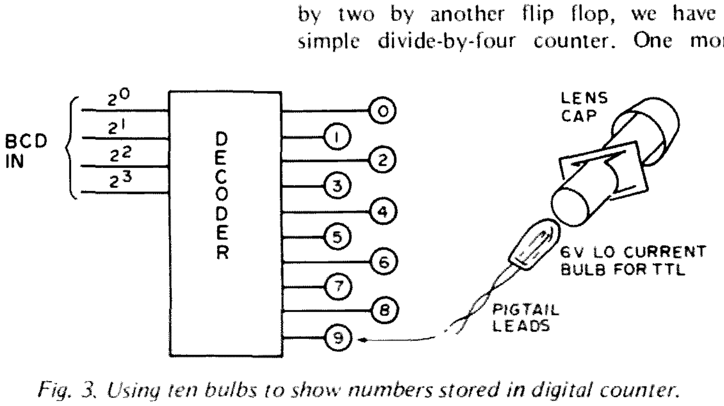

Fig. 3. Using ten bulbs to show numbers stored in digital counter.

Fig. 2 shows one way to modify the count. The four stage counter would normally divide by 16 (2^4 = 16). Notice that at time t_0 the output of the counter is reset by the combination of outputs from the stages. The counter will count from t_0 to t_9, then reset and start all over at t_0. This gives divide by ten action. In fact, this counter is called bi-quinary, since the first stage divides by two, and the last three stages divide by five.

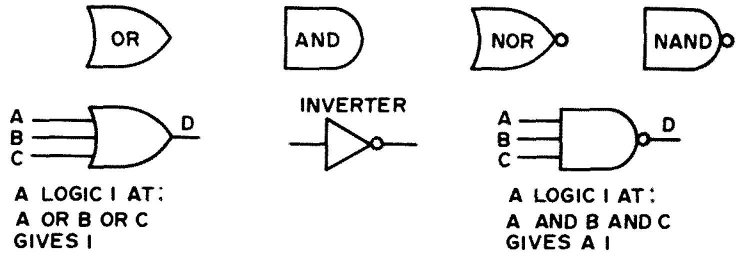
This is the same basic logic used in the popular 7490 divide by ten IC. The output of the counter is not only divided by ten but is BCD. BCD means "Binary Coded Decimal."

That's where the storage capability of the flip flop enters the picture. A lone negative pulse in will flip it (or flop it, if it were already flipped). If no other pulses come along, the flip flops will remain the same and the number of pulses will be stored in a counter. In fact, because of the BCD action, a seven pulse in would give an output from the four stages of 0111 (binary for decimal 7). If the counter is reset and we let in say, thirteen pulses, the stages will flip flop along until they count to ten and then start over again. The three remaining pulses would cause the counter to sit at 0011 (BCD for 3). What happened to the 1 in front of the 3? Simple: It spilled over to the next decade counter if there was one. So, the first counter counts units, and the next one counts tens. With 27 pulses, two decade counters would store 7 (units) and 2 (tens). So putting the first decade on the right and the second on the left would give 2 – 7 or 27. With readouts connected to our counters, we would be able to read our numbers just like the numbers on a written page. Just hook up a light bulb to the stages in each decade for an instant readout.

Of course the readout would be BCD. For 27 that would be 0010 and 0111. That's not too hard to read, if you remember in binary you have only a two digit base – 0 and 1. And think of the action of the decade counter. The counter on the right counts digits and the one on the left, tens. Well, in the BCD system the digit on the right counts units just like in the decade counters. Remember that there are only two counts, not ten, so the next digit to the left counts twos. The next one can count up to two twos (that's four). The last digit is eights. So the BCD 0110 is (from the right) no units, one two, one four, and no eights. Add them up. That's four plus two, or six, so 0110 BCD is 6 decimal. Now it is easy to read the lights and tell what is in the decade counters.

With all the miracles of electronics, it's pretty easy to build something that lights up to ten lights with little 0 through 9's stenciled on. You just look and see a display in decimal as shown in Fig. 3. Decoding the BCD and converting to decimal to light up the digits is accomplished by using a decoder made up of a system of gates.

Just as flip flops store and divide, gates decode and control. There are two basic gate functions and all others are variations of these functions. The two basic functions are AND and OR. The AND gate has to have its inputs applied together to have an output



A	B	C	D
I	I	I	I
I	I	O	I
I	O	O	I
O	O	O	O

A	B	C	D
I	I	I	I
I	I	O	O
I	O	O	O
O	O	O	O

Fig. 4. Logic symbols with truth tables for OR and AND.

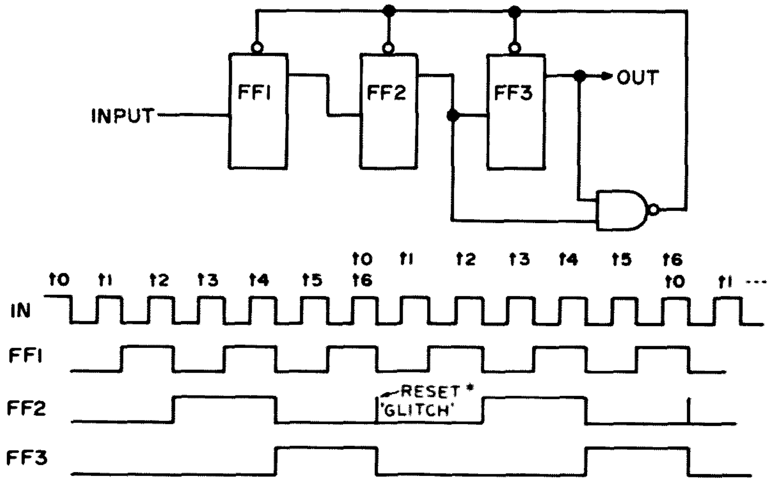


*Fig. 5. Divide by six counter. *Because of the "glitch" at FF2 and fast switching times of some flip flops, you may get FF3 flipping again. You may suppress the glitch or divide by a non-reset flip flop at the end of the counter. One of these, followed by a decade (÷10), gives a one second output from the 60 cycle ac line.*

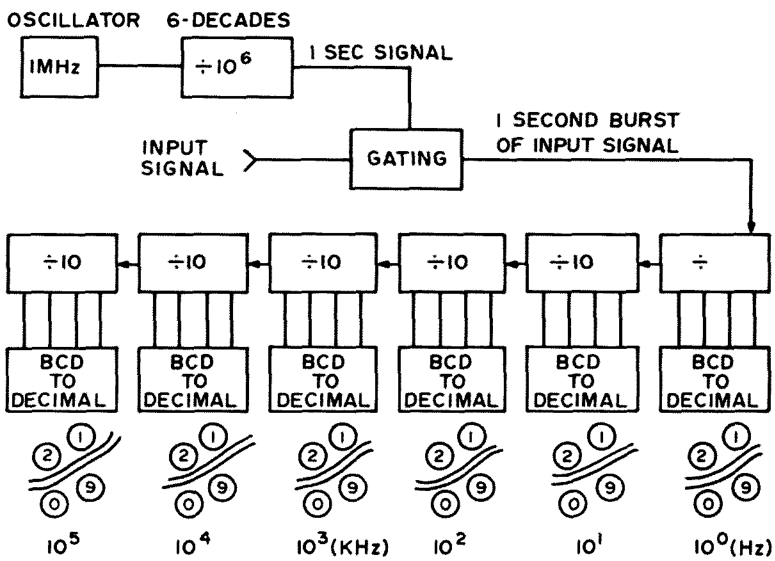

Fig. 6. Basic counter block diagram. Frequency readout in Hertz.

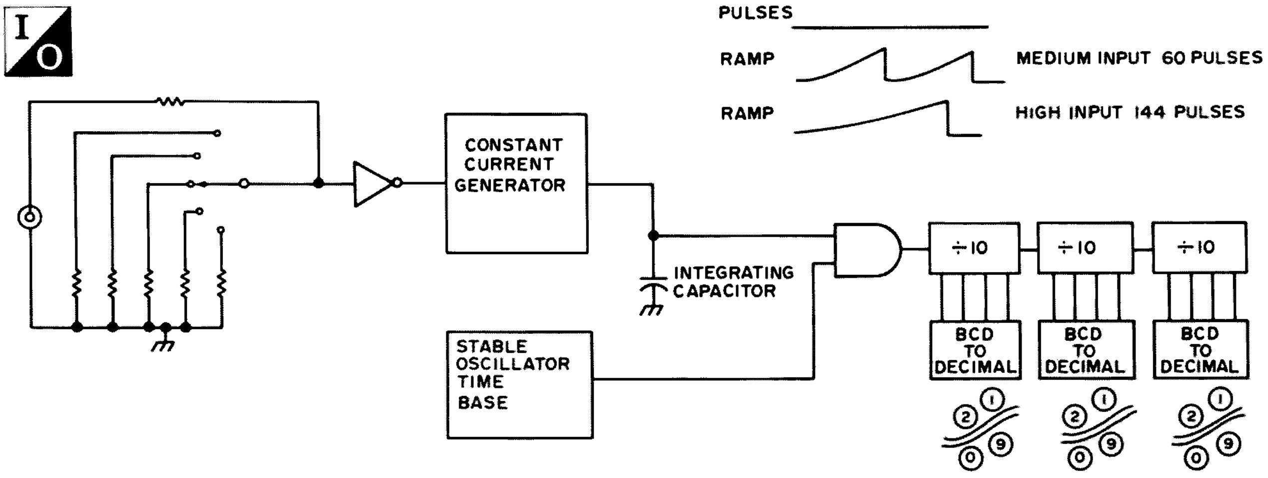

Fig. 7. Basic slope integrating DVM, showing some relationships between the slope wave forms and the timing pulses.

(an "output" and "input" are considered a logic 1, or positive voltage). The OR gate takes one input "or" another "or" any other to get an output. An inverter (common emitter amp) following either of these gates inverts it and you get NOT AND or NAND and NOT OR or NOR. That means a one AND a one give a zero and a one OR a one give a zero. It's upside down logic but it comes in handy. To abbreviate the circuit you use the logic symbols shown in Fig. 4.

Now let's take a three stage (divide by eight counter) and do some fancy counting. To divide by six we need a count of 101 (binary equivalent of five) maximum – then when the count hits 110, six, we want to reset the counter to zero. So, simply use a two input NAND gate (it takes a zero to reset our counter stages). You end up with Fig. 5. That's a good beginning for a clock. Just divide by six, then divide by ten for one second outputs from the 60 Hz ac line. Just hook up the decade displays and you can count the seconds. If you modify the decade displays so the second one from the right counts to six and then resets, and the fourth one from the right does the same, you will count up to 60 seconds and spill over the next two digits to the next counter pair (in which the far left digit only counts to 2). At 11 hours 59 minutes and 59 seconds, your clock reads noon (or midnight) and one second later all the counters go to 00:00:00. You can eliminate the seconds readouts in a practical clock, but you have to keep the divide by ten and divide by six counters to feed the minutes counter.

The digital clock is obviously pretty simple. How about a counter? That's somewhat more complicated, but only because of

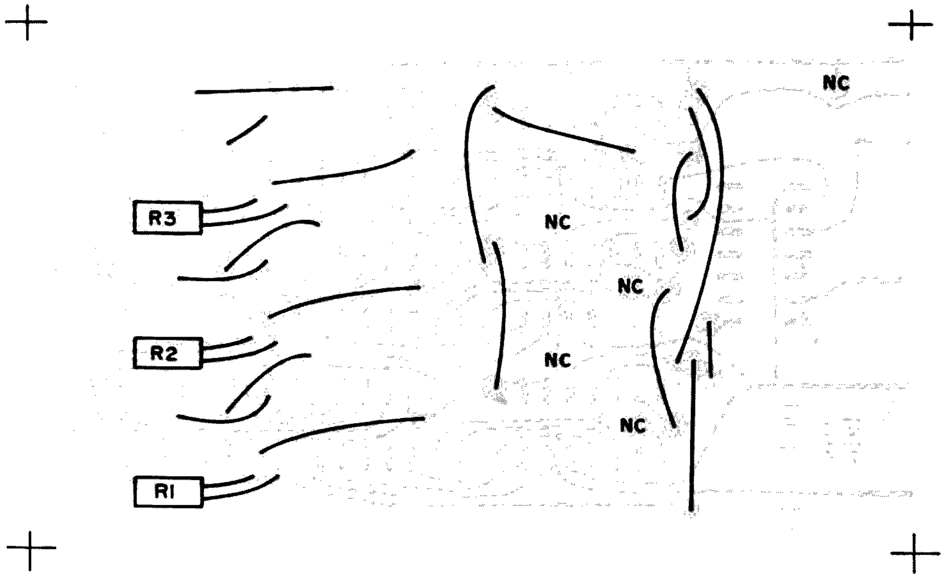

Fig. 8. Jumpers and IC alignment diagram.

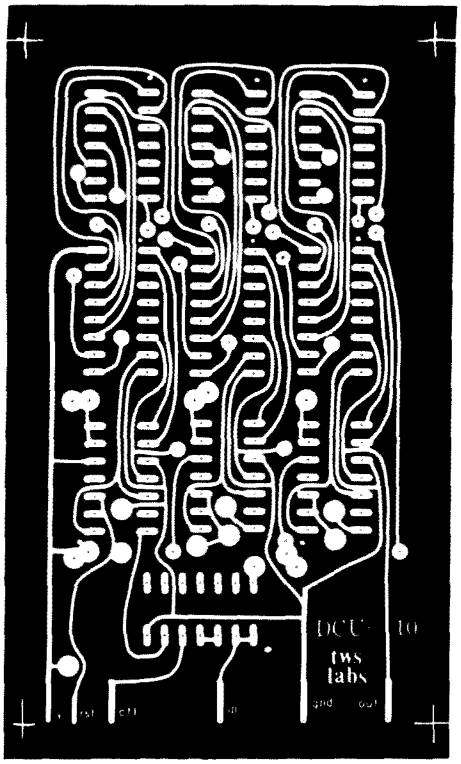

Fig. 9. Foil side, PC board (full size).

the gating. This time we will consider the gate controlling function as well as its decoding function. Fig. 6 shows very simply how a counter works. For one second the gate is "open" or enabled, and the decade counter stages divide away. At the end of that second the gate gets closed and the decade counter stages sit and hold whatever count came in. If the input was, say, 7174 Hz, those are the numbers that will show up on the display – because in one second there were seven thousand one hundred and seventy-four negative transitions counted. Obviously, the accuracy of the one second gating signal is important; that's why you are likely to use a 1 MHz crystal oscillator, divided by a million (6 decades), so any errors are divided by a million, too. You must also reset all the display counters just before you start counting. Otherwise, the first time the counter will show 7174 Hz and the next time 7174 more, so the display will show 14348 Hz (unless you run out of digits). You can see, too, that the gating signal could be 10 Hz; now you can count to a tenth of a cycle for super accuracy. The gating signal can be faster than one second, too. A 1 ms signal will display kHz. Selecting the length of timing signal (and where to put the decimal) depends on how many readouts you have and the maximum operating speed of the gates and counters. A basic counter contains a timing circuit, gating circuit, gating, and displays.

How do you get a DVM? There are a couple of methods. One is simply controlling

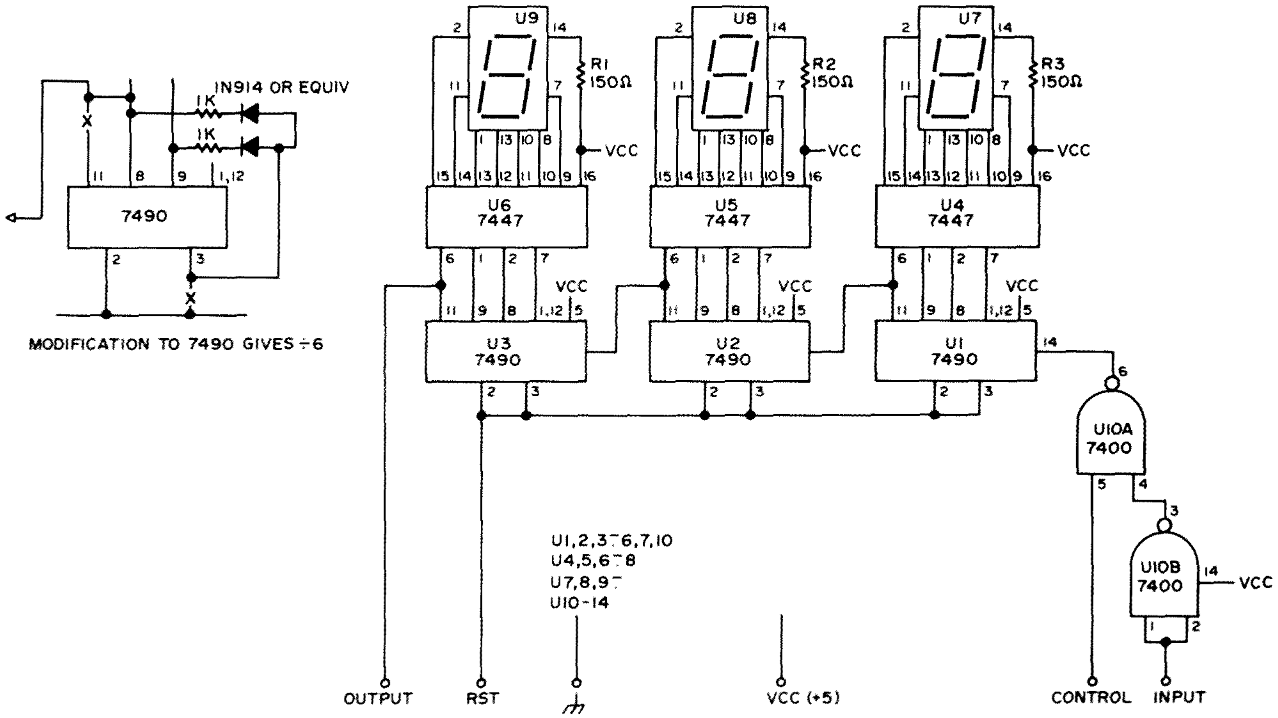

Fig. 10. Schematic diagram with modifications for clock and counter applications. Note: Link all pin 3s on 7447s and ground, for blanking readouts during count in counter if desired.

1. Insert wires through top of board (Fig. 8) for top 1/3 of board.
2. Check to insure no two wires cross and no wires cover or cross IC pin holes.
3. Stick in readouts and 7447s to hold wires in place while you turn board over and solder wires in place.
4. Solder in only 7447 ICs and trim wire leads. DO NOT SOLDER READOUTS IN YET. Make sure 7447s are in right-side-up before soldering.
5. Insert and trim the three wires in the middle of the board.
6. Insure wires do not touch, and solder and trim.
7. Insert wires in the lower third of board; make sure there are no wires touching or crossing IC pin holes.
8. Solder, trim, recheck for wires touching.
9. Insert 7490s and 7400 gate; observe markings to keep from putting ICs in upside down.
10. Solder in ICs and prepare to mount readouts.
11. Insert readouts.
12. Put board against flat surface foil side up and push readout pins down until readouts are aligned and are even with tallest ICs on board.
13. Solder only pin 1 and pin 8 on each readout.
14. Turn board over and readjust readouts as necessary to make the surfaces line up with each other.
15. Carefully turn over and solder the remaining readout pins.
16. Run jumpers on foil side of board from pin 14 on one IC to pin 11 on the other. Allow one side of the wire to stick roughly 1/8" through front of board – this will become a test point.
17. Make sure jumpers clear all pins on foil side of board. Solder jumpers.
18. Run two approximately 2" long insulated wires from the guide hole and pad near the board + 5 input terminal.
19. Connect each wire to the pad that connects the bottom of R2 and R3 (Fig. 8) to pin 16 of their respective 7447s.

Table 1. Step-by-step construction.

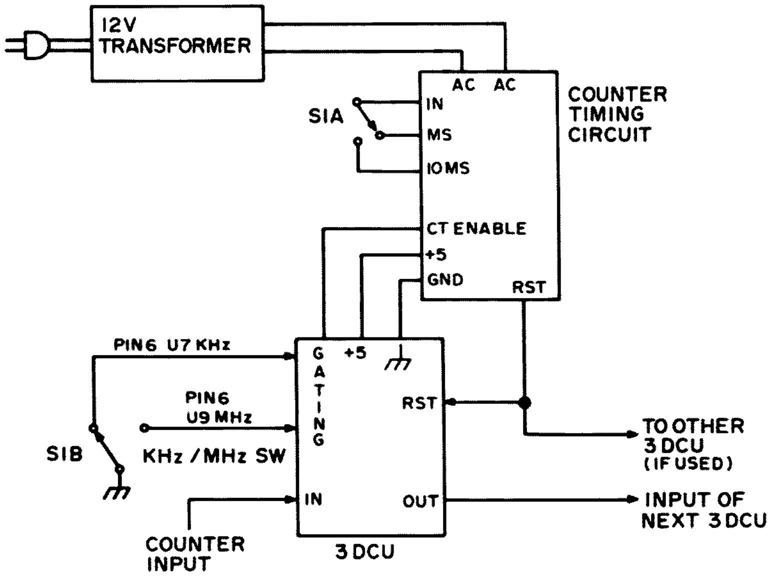

Fig. 11. Connecting a 3 DCU for a nearly 30 MHz 3-digit counter that can read out a transmitted frequency to 100 Hz. Adding the other DCU makes a 6-digit counter that will indicate to 200 MHz with a preselector.

the frequency of an oscillator with a voltage – a VCO. The better method, one you've probably heard of, is the slope integration method. You merely control the output of a constant current generator with the input voltage. The constant current generator feeds a relatively large capacitor. The capacitor either charges in a hurry (large input voltage) or trickles (low input voltage). The charging of the capacitor generates a ramp voltage. The ramp turns on a gate and the gate stays open as long as the capacitor charges. While the gate is open, a timing signal puts pulses through it and the decade counters count and display the pulses. Fig. 7 shows the basic circuit and wave forms for a "slope integrating" DVM.

Well, by now you're probably ready to try your luck at some digital beauty. You may not be too excited about the ten light bulbs for a readout, so just use the popular seven bar types. The seven bars are decoded to shape the forms of numbers 0 through 9. A decoder is available for them and even contains drivers for the LEDs in the 7 segment readout. The decoder is appropriately called a BCD to 7 segment decoder/driver.

The 3 DCU project uses 7 segment readouts and IC decade counters for compactness. The entire three digits fit on a 2" x 4" PC board. A single sided board was used to allow versatility. You will have to run a few jumpers (or use the diagram showing the jumpers for the standard DCU to lay out a pattern for the other side of your board, if you don't want a special application). You can etch your own cards or buy one already etched and drilled. In fact, you can get a complete kit of parts from TWS Labs, PO Box 357, Provo UT 84601.

Begin construction by putting in the jumpers as shown in Fig. 8. Step-by-step assembly instructions are given in Table 1 for a foolproof assembly. Fig. 9 shows the PC layout (foil side). Fig. 10 is the schematic.

After assembling your 3 DCU, check out operation by connecting +5 and ground. Run a ground to RST, and then touch a ground on and off the input terminal of the card. The digits should flash away. If you could actually touch only once, you would be able to count the times you touch the ground. The decades will count up to 30 MHz and, though you may think you touch only once, chances are you will touch the ground many times and the decades will tick away. As long as they count pulses, you will know the 3 DCU is working. Test reset by removing its ground – the 3 digits should go to zero.

Applications

The applications for 3 DCUs are nearly

unlimited: For example, they will work to 200 MHz with a preselector. A pair of 3 DCUs side by side gives a 6-digit counter. An FET, UJT, and time base, along with a 3 DCU, will make a great DVM.

Counter

Currently, there is a timebase and power supply kit available from TWS Labs that makes a great counter for ham rigs when used with a 3 DCU. Fig. 11 shows how to hook up the timebase. With two 3 DCUs and the timebase, you can have a 6-digit 20 MHz counter.

Timer

Obviously, 3 digits are perfect for a 10 minute timer for ID purposes. You modify the middle digit to divide by six instead of ten (see Fig. 10). Now merely feed the DCU with one second pulses. This can be ÷6 and ÷10 the ac line or ÷ million a 1 MHz crystal. Just use an n/c push-button switch to keep the reset line grounded. Thus, when you want to reset the clock to 0:00, you just momentarily depress the switch. As soon as you let up, you remove the reset and the 3 DCU starts ticking off the seconds again. Fig. 12 shows a 10 minute ID timer set up using 3 DCU. A kit to make a 10 minute timer with power supply and warning lamp is also available from TWS Labs. All you add is a 3 DCU.

Clock

Add one more 3 DCU (modified for 6 count as mentioned before) to the 10 minute timer circuit, and you have a digital clock. Fig. 13 should give you some ideas on how to hook it up for 12 or 24 hour operation. For a clock you must have a way to set the time, so a fast advance and a hold position are used. You merely advance the clock slightly past the desired time and then hold the count until WWV beeps, or whatever; when you let up, the clock starts ticking away the seconds. A clock addition is also available from TWS Labs.

DVM

This one will take a little experimenting on your part because the only kit available is for converting a frequency counter to a DVM. If you are using the timebase kit with your 3 DCU, it may work. It is available for $9.50 from R. S. Stein, 1849 Middleton Ave., Los Altos CA 94022. (Note that this is a PC board for the DVM only.) If you want to experiment, you might try Fig. 14 for ideas. If you allow your 3 DCU to trigger an external flip flop and drive an LED, you will have the makings of a 3½ digit DVM. Once you are measuring volts, it

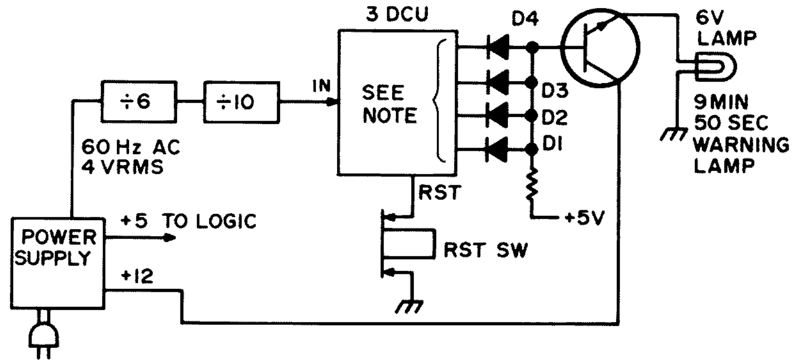

Fig. 12. Hook up 3 DCU as a 10 minute ID reminder. Warning lamp goes on at 9 min 50 sec, for 10 seconds. Note: D1 = pin 8 U1; D2 = pin 9 U1; D3 = pin 1 U3; D4 = pin 11 U3. U2 modified to ÷6 (see Fig. 9).

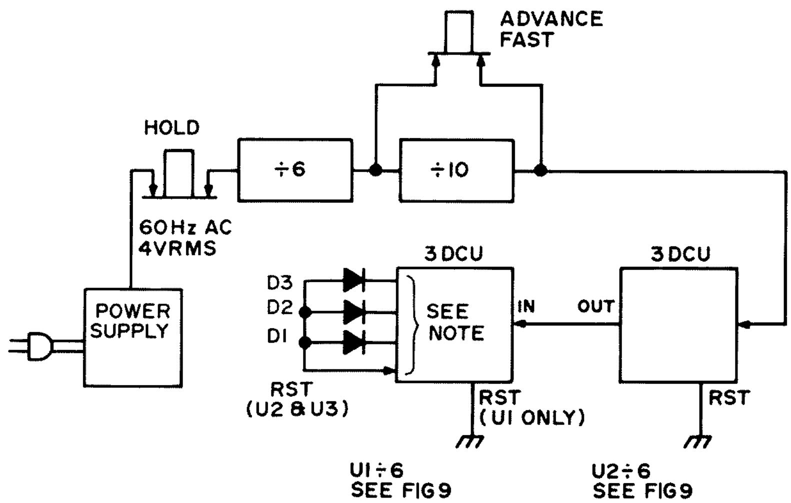

Fig. 13. 12 and 24 hour 6-digit clocks using 3 DCUs and simple fast advance and hold switching. Note: For 12 hour clock, D1 cathode = pin 1 U3; D2 cathode = pin 8 U2; D3 cathode = pin 1 U2. For 24 hour clock, D1 cathode = pin 8 U3; D2 cathode = pin 9 U2; D3 not used.

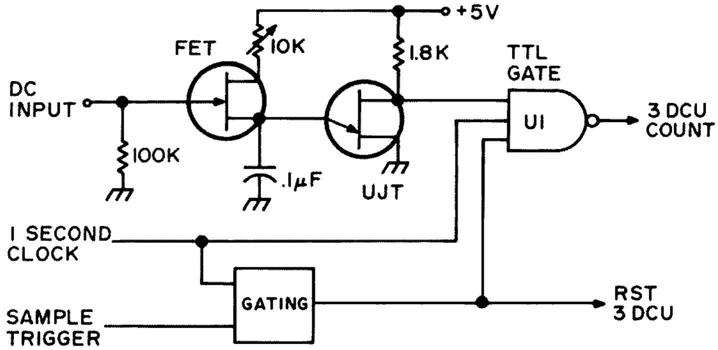

Fig. 14. Here is a place to start. For a simple DVM, the FET current charges the capacitor in the UJT relaxation oscillator. Then gating allows the 1 sec clock to enable gate U1. Then, depending on the frequency of the UJT, pulses will pass through gate U1 and be counted in the 3 DCU. Make it so 1 volt equals 100 pulses into the DCU.

will be easy to measure current (voltage dropped across a standard resistor), Ohms (standard current through the unknown resistor), ac (using a rectifier system), etc.

Well, I'm sure you found one or many ideal projects for your ham shack using a 3 DCU or two. I have several units around the shack and they are all as handy as can be. Although we've only scratched the surface, some of you will probably add preselectors to your counters for 200 MHz operation. Use 3 DCUs for counting dial pulses – only you and your imagination know for sure. For whatever the use, you'll enjoy entering the fascinating world of blinking digits. ■

Parts List (refer to Fig. 10)

R1,2,3	150Ω ¼ resistor
U1,2,3	7490 decade counter-TTL
U4,5,6	7447 BCD to seven bar decoder/driver
U7,8,9	Seven bar readout Opcoa SLA 1 or equivalent common anode
U10A,B	7400 quad, 2 input NAND gates (only two used)
PC board	PC board for 3 DCU available for $2.50 ppd. (See below for address.)
*Kit	Complete kit of all parts, including PC board, all ICs, instructions, and readouts, as well as applications for 10 minute ID timer, stop watch, digital counter, 6-digit clock, etc., is available for $17.99 plus postage from TWS Labs, PO Box 357, Provo UT 84601.

like 2 meter ham gear. I bought a 45 and now want a 65. Bought a Multi-2000 and now they have a Multi-5000. Ah, well – guess that is the price one pays for not waiting to see what the market will offer in the future.

Keep up the good work with the magazine.

Don't Forget Our Gals

This is my first subscription to *73 Magazine*. This is truly a fantastic book. I am not a ham operator, although I would like to become one. I just enjoy electronics and hobby work. I am not that advanced in electronics, but I enjoy very much reading and learning about ICs and how they operate. Keep up the good work fellows – you have a good thing going.

Lumberton NC

Walk on Water?

The reason that I'm writing to you is that the November issue of *73* has just arrived and I have this tremendous pressure to congratulate you. It's been a long time since 1960, Wayne. So – my most sincere admiration and best wishes! I think you are ready to walk on water – barefoot. And thanks from my Novice friends for your books, tapes and the magazine.

Ken Cole W7IDF
Vashon WA

African Report

I thought I would drop you a line to say I have really enjoyed your *73 Magazine* since finding it in the BX. I had a Novice ticket a couple of years back. Since I have started to read your magazine, my interest in amateur radio has been reawakened. I have taken the Conditional test and now I am waiting on the FCC to reply. I would like to see some articles on the new Heathkit HW- and SB-104s, in addition to more on the HW-7. My only other point is, how would you like to be in Addis Ababa, Ethiopia, at 9000 feet with excellent signal reception, and not be able to operate due to government restrictions? Anyway, I do listen to all those rare African stations – and wish.

Carl L. Moss
Addis Ababa
Ethiopia

P.S. Saw *73 Mag* on sale in Athens, Greece in August at various newsstands.

Denver Oining – Etc.

I think it would be nice if you would sponsor a US-wide ham meeting and luncheon directory.

Denver has two open clubs and two weekly open luncheon groups, and many other cities have the same. Many hams would work their travel itineraries around in order to attend some of these groups if they could know where and when in advance.

I would appreciate it if you could put a small notice in your magazine of the "Hams East" and "Hams West" luncheon groups in Denver.

Both meet in cafeterias, start at 11 am and continue until the last ham leaves. No programs, no formality. Just lots of good rag chews. Wives are welcome and many attend.

"Hams East" – Tuesdays, 11 am, Wyatt's Cafeteria, 2466 S. Colorado Blvd., Denver CO;
"Hams West" – Thursdays, 11 am, Wyatt's Cafeteria, Alameda Ave. and Wadsworth (Villa Italia Shopping Center), Lakewood CO (Denver's largest suburb).

Big plans are being made for the 1976 convention, and since everyone seems to get to Denver sooner or later and we really believe in welcoming strangers, don't overlook our two weekly ham luncheon opportunities. The 146.07 T – 146.67 R Castle Rock Repeater Group repeater exists for the sole purpose of rag chewing. All breakers are recognized; traffic information, road and street directions, phone patches, traffic, and what have you is handled and never a discouraging word. We do not put up with smart aleck guys who object to what type conversation or use (it must be legal) our repeater is used for. Our only insistence is that all breakers be recognized and rag chews cease until the breaker's inquiry or needs are met.

Remember – pass the word – 146.07 T-146.67 R is an open repeater with a 3 minute timer and visitors and their needs are at the top of our priority list. Above all, don't be afraid to "break." We expect you to, and, should anyone experience any discourtesy, the matter will be positively dealt with by the group members. I am glad to say that this situation occurs so rarely on this repeater that I can't even recall the last time, and we all hope the last time was truly the last.

Howard A. Moore K0HPF
Lakewood CO

HP-45 Fun (Cont.) (Cont.)

I have been reading *73s* for several years and this is my first attempt to write and say just how pleased I have been with the magazine. It's just plain fine. Keep it up.

In regards to the article that appeared in Letters (October 1975 issue) entitled "HP-45 FUN," the gentleman tells how to call out the timer mode on the HP-45. Well, this is all fine and dandy, BUT it has one major problem in that the timer runs slow (not 60 counts of the timer = 1 minute in real time). I've made several checks with the HP-45 vs. WWV and a counter, and found the HP to run about 14% slow. I've also checked other HP-45s and they seem to be the same way.

Just thought this info may be of interest to the readers, and users of the HP-45.

RTTY Autocall - the Digital Way

by
L. W. Sanders VE6BV
2404 37 St. S.W.
Calgary
Alberta T3A A39

As earlier versions of a character recognition device were called "Selcal," it would only follow that newer versions would be called "New Selcal." However, I will stand on the name character recognition device, for that is the only correct way to describe the following unit.

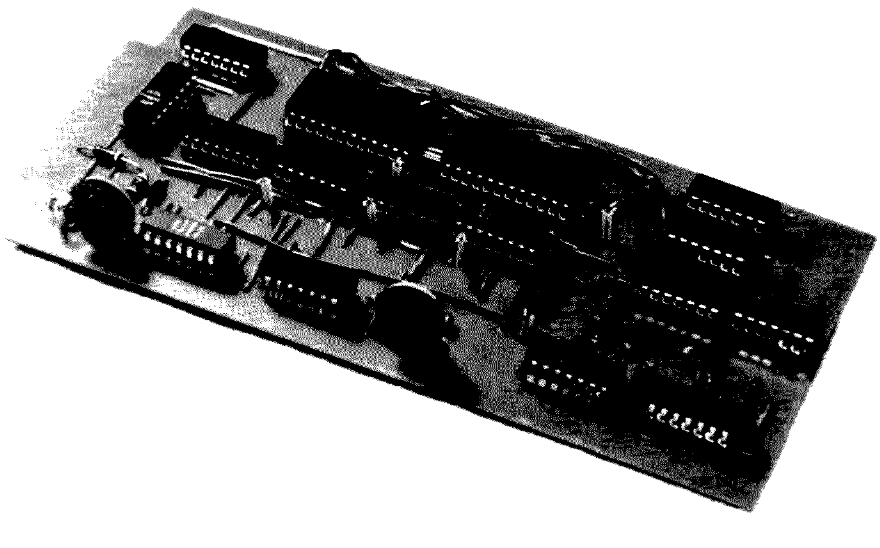
Most previous Selcals had long and detailed methods to decode one character at a time, then another character, and so on, by means of gates, inverters and such. This unit decodes all letters of the alphabet as well as all machine commands, by means of its inherent design. All that is required to change a decode structure is to move 4 wires. Decode can be changed in less than 3 minutes and without paper, pencil, or decode charts, etc.

Again, earlier Selcals used transistors, diodes, KCs and many resistors and condensers. This unit uses ICs, 4 resistors, 2 condensers, and 1 diode. Size again was something else. Some boards that I have seen were 12" x 12" = 144 sq. inches, others, 8" x 8" = 64 sq. inches. The newest CRD (3" x 7" = 21 sq. inches), is fitted with a 12 pin edge connector and will fit inside a Hal ST6 teletype demodulator nicely.

This new CRD includes (as do the Selcal units) such features as the $\overline{\text{NNNN}}$ shut down, force on/off, and four character decode.

A second feature has been added, with which I will now blow some minds.

For most amateurs the acquisition of a model 28 teletype unit and its stunt box is just a dream, but take heart, for with the STUNT BOX CRD unit, the lowly model 12, 14, 15 or 19 can now have the stunt box features of the 28.



Mother board, top view.

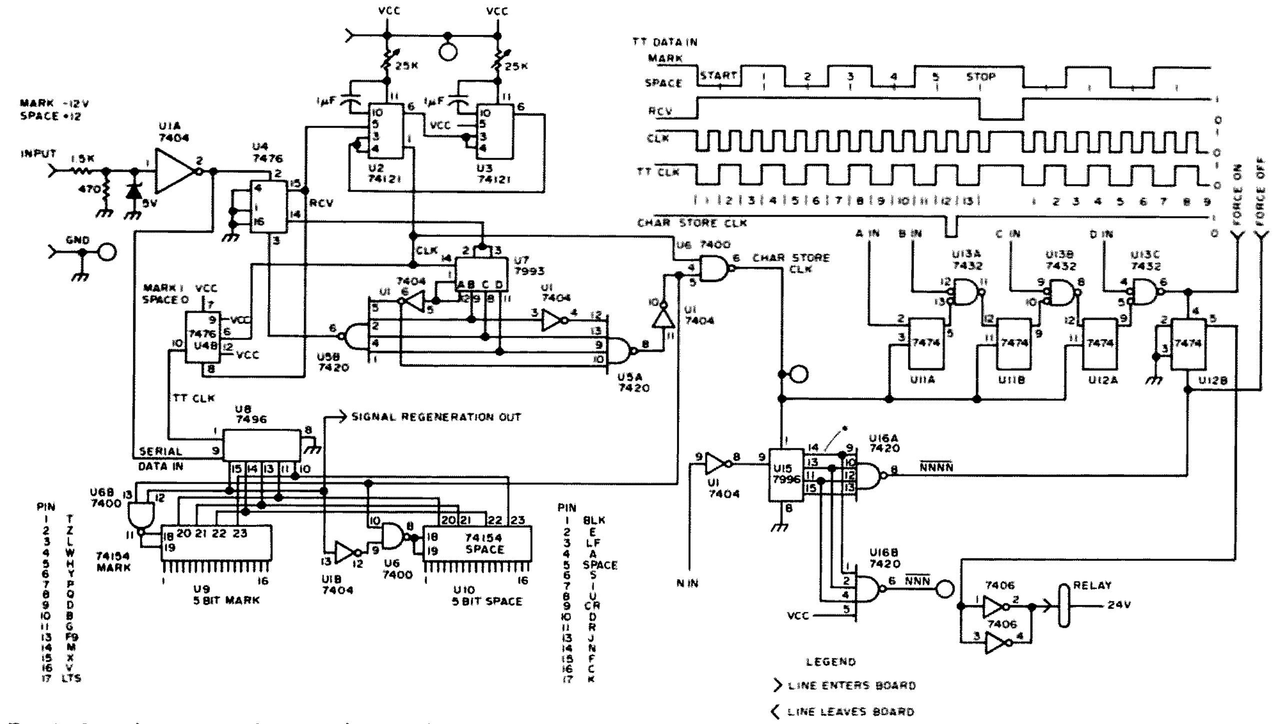


Fig. 1. Complete circuit diagram along with a timing chart.

The model 15 that I own is just about as loaded as I could make it, but I still needed more functions, for station accessories such as keyboard-operated perforated turn on/off and T.D. turn on/off transmitter control.

When a 100 wpm machine becomes available, I will use an electronic speed converter and the CRD to allow incoming signals to change speeds for me.

Also in this area, hams may have the opportunity this winter to access a minicomputer via a 2 meter transmitter to a terminal station, then again via RTTY to the computer, thus needing auto transmit, shut down and ID on the terminal station. The CRD stunt box will do it for us. 'Nuff said.

All this, remember, is in a 3" x 2" x 7" cube still inside an ST6 cabinet.

As an active autostart frequency exists in the western area of Canada and the northwestern United States, and there is a lot of traveling in my work, I would find, upon returning home, a large amount of paper to be inspected and possible queries to be answered.

A selective calling device had to be installed. After looking at many different designs I made an attempt to build one. A RTTY Selcal with TTL logic only met with dissatisfaction and an unstable decode system. After approaching Cal W9ZTK, he suggested a new approach to the decode trouble; a CRD with TTL logic was begun. This unit further reduces the number of integrated circuits required, plus it appears to have several most desirable features as well.

As to the ease of changing decode structure, having just received a new station call, I timed myself. It required 3 minutes to set up a total new decode structure.

In the photos a hand wired board is shown as well as a finished mother board. The hand wired unit was made up to test a stacked board concept and still only have one edge connector. It worked, and this opens up a new idea. How about a stunt box as well as a CRD? Herein lies an article.

A complete circuit diagram along with a timing chart is given in Fig. 1. When going through the theory of operation, check Fig. 1 or the individual circuit drawings, which will assist in understanding the operation of this unit. Some logic levels are given, in particular, on the shift register, character recognizing drawing.

The following approach to a selective calling device is unique. First, all 32 keyboard signals can be detected and used in the decode sequence. There is no need for charts, truth tables or what have you. One wire from a character output to decode input is all there is needed.

Liberal use of TTL logic circuits has all but eliminated any chance of the unit not operating, as well as keeping the cost down. In fact, there are only four resistors, two condensers, and one zener diode on the board; of these, two resistors and the zener are interface components.

The CRD is usable as a selective calling

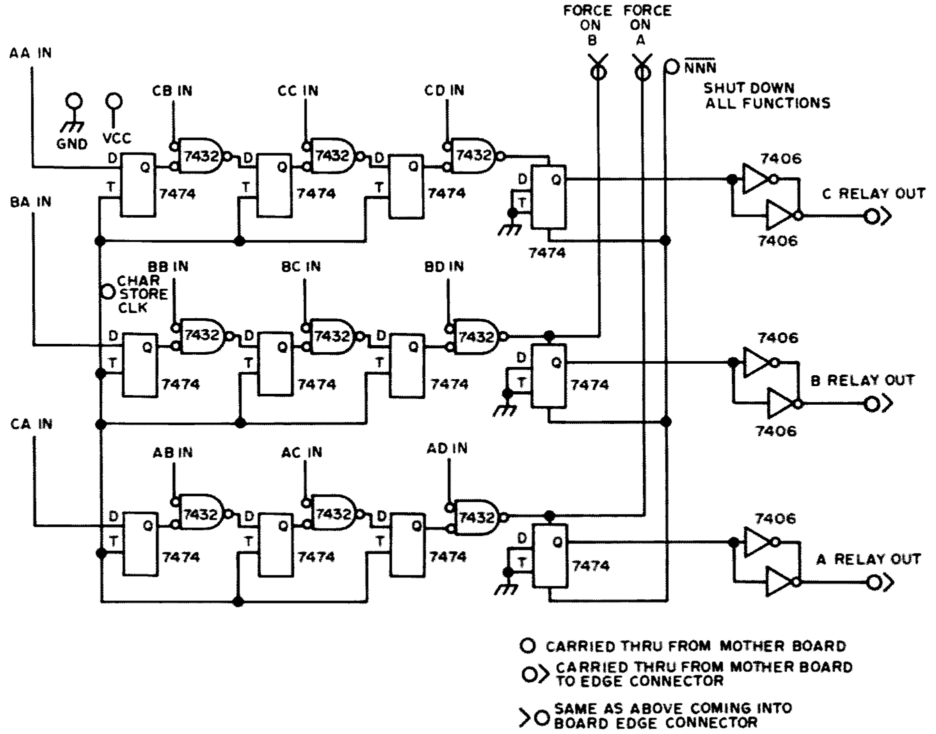

Fig. 2. Stunt box board.

device as well as a local stunt box at the *same time.* This itself is new. In fact, the whole thing is new.

Theory of Operation

The incoming TTY signal (data) is the standard FSK line. This line is going from 12 volts minus (mark) to 12 volts plus (space). This voltage is applied to a voltage divider comprised of a 1.5k and a 470 Ohm resistor. A 5 volt zener diode is placed in shunt with the 470 Ohm resistor. This limits any input signal that is greater then the proper TTL input level. Output of the inverter is fed to a 5 bit shift register, as well as a control flip flop.

Control Flip Flop

This half of the flip flop controls the start or stop of a stable clock. As the space data comes in, it is inverted in U1a putting a low on pin 2 (set) which causes pin 15 to go high where it will stay until a clear pulse comes along, to change the state of the flip flop. The high on Q pin 15 is fed to the enable pin of a monostable multivibrator or clock.

The **CRD** is usable as a selective calling device as well as a local stunt box at the same time . . .

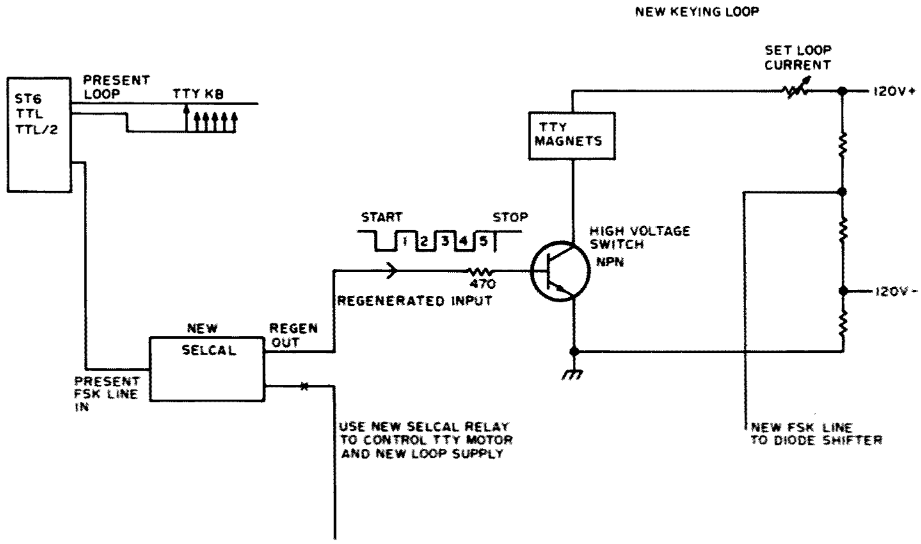

Fig. 3. Station interface.

NOTE 5th BIT SELECT

Fig. 4. 74154 truth table.

Clock

This clock is very stable; temperature and supply voltage changes appear to have little effect on its frequency. As the control signal is applied to the Schmitt trigger input (pin 5) pulse, triggering occurs at a certain level of rising voltage on this pin. When the monostable fires, the output pulse width is independent of the input pulse signal. The output pulse width is controlled only by external timing components, in this case the 25k variable resistor and the 1 uF condenser. The output pulse from U2 (pin 6) is fed to U3 (pins 3 and 4). As the Schmitt trigger input is tied to Vcc the second monostable is fired as soon as it gets a negative going pulse from U2 (pin 6); here again output pulse width is independent of input pulse width, being again controlled by the 25k variable resistor and the 1 uF condenser. The output pulse of U3 (pin 6) is fed back to pins 3 and 4 of U2. Hence a train of pulses are generated and will run on forever or until U2 (pin 5) enable is taken to ground or low. *Notice:* There are two timing pots on this clock. One pot sets the pulse width or time on and the other sets the pulse repetition rate or off time. The clock signal is 5.5 ms on and 5.5 ms off for 60 wpm. The output clock signal is fed to a divide by 16 counter, a divide by two, as well as a gate.

Divide by 16 Counter

When the control flip flop U4 starts the clock, Q pin 15 is high; therefore, pin 14 is low. This signal is applied to pins 2 and 3 of the divide by 16. This enables (pin 1, U2) allowing the clock pulses coming in to be counted. When the count twelve is reached, gate U5a changes to a low which is inverted by U1b and applied to one input of NAND gate U6a. As the other input to NAND gate U6a is coming high at this time, a negative going pulse is formed. This pulse is used to clock the character store. As the clock U2 (pin 1) is still running, at this point U7 continues to count. At clock pulse 14, gate U5b detects all highs at its input, which makes pin 6, U5b low (which in turn is fed back to pin 3 of U4). This low makes U4 change state; pin 15 of U4 goes low – stopping the clock. U4 (pin 14) then goes high, resetting the divide by 16 counter to zero.

TT Clock

While the clock pulses (U2, pin 1) are going to the divide by 16 U7 and U6a, it is also being fed to U4b, pin 6; here it is divided by 2 and the (pin 10) U4b not Q output is now 11 ms wide. This signal is used to clock data into the shift register U8, pin 1. When a TTY signal is received, inverter U1a sends a signal to U8, pin 9, where it sits until a clock pulse comes to shift it into the first register. It sits there, waiting as well as the new information on pin 9, which is also waiting to be clocked into the first register, with the information in the first, moving on to the second. This action continues until all seven bits of data are entered into the register. But I do not need all the seven bits; just the middle five contain printing

Mother board with stunt box board, top view.

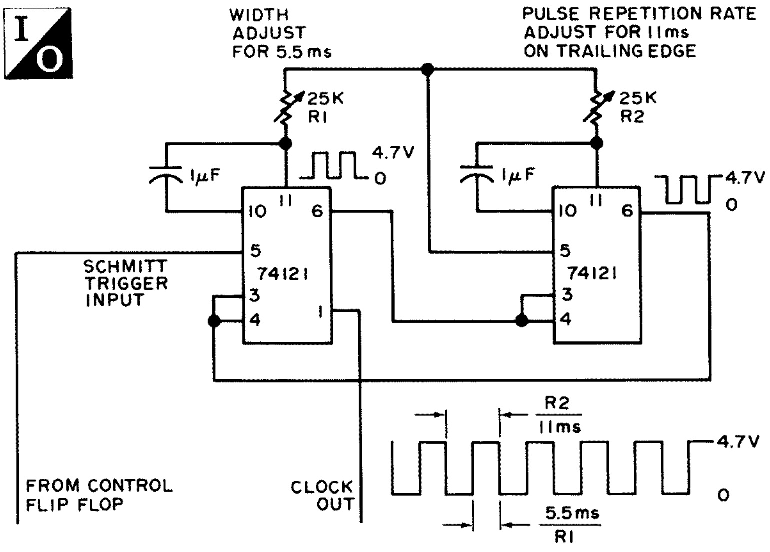

Fig. 5. One shot clock.

information, so at the time the first bit is shifted out of the register, the five needed bits of printing information are in the register. At this time the outputs are inspected and information contained in the register is passed to a four line to sixteen line decoder. By the way, the inspection takes place on the last part of count 12. (See TTL clock timing chart.)

Character Inspection and Decode

At count 12 gate U5a goes low, inverter U1b is high. This signal is fed to U6b input one as well as U6c. The output of U8 contains printing information in its 5 registers at this time, using only the four outputs to address a four line to sixteen line decode 74154. As this chip is addressed in binary, I can say that the output of U8 is a binary word msb (most significant bit) 01101 lsb (least significant bit). Forget for just a short time the msb 0. Let's look at 1101; this is binary number 13. When I check the truth table for a 74154 chip, I find a low on output 13 with all other outputs remaining high. If binary number 0001 were addressed to this chip, what output would be low? Correct, it is output one. Now you can see how by taking a 4 bit binary signal and applying it to a four line to sixteen line decoder I will get only one low output for any binary number, input from 1 to 16. Serial baudot information is five bits long, so now take the 0 that I set aside a few moments ago and feed that 0 to a gate U6b and an inverter U1d, which in turn feeds second input U6c. A high and a low on U6b inputs will not allow U6b's output to go low; thus U9 pins 18 and 19 are inhibited, and all outputs from U9 will be high. But a low on inverter U1d gives a high out to U6c. A high on second input of U6c gives a low at its output, which enables U10, allowing output 13 to go low, where all other output pins remain high. Hence, I have decoded one out of thirty-two possible TTY combinations. One note U9 decodes all characters with the 5th TTY bit a mark, and U10 decodes ones with the 5th bit a space. The job is just about done now.

Sequence Character Recognition

As I decode only one combination of TTY binary at a time, I must store them so that a series of characters allows a turn on or turn off. This is done by feeding a selected character into a type D flip flop. If information is fed into the D input of the chip, it is passed on to the Q output at the time of the clock pulse; Q will stay in this state until the next clock pulse.

The Q output is now low (pin 5, U11a). When we place a second input low on U13a (taken from selected 74154 output), the output of U13a remains low. This low is fed to the D input pin 12, U11b. At the next clock pulse this low is transferred over to the Q output of this chip, and so on until the four selected inputs or turn on has been received. If a wrong character is received, the whole chain must be started again. For A in, B in, C in and D in must go low, each in turn for the correct turn on to be made. When the fourth character has been received, output pin 6, U13 goes low which sets U12b and makes Q pin 5 high. This high is fed to an open collector inverter which in turn goes to ground pulling in the motor control relay.

$\overline{\text{NNNN}}$ Shut Down

Because the N signal is low when selected from 5th bit space 74154, an inverter is used to get correct sense on data input to another 5 bit shift register U15. When four Ns are received in order, the output of the shift register is high. When fed to a four input NAND gate, output goes low (U16a). This signal is sent to the clear input of the relay control flip flop U12b making its Q output go low and the open collector inverter's output high, turning off the relay. A second four input gate U16b is set up to give an

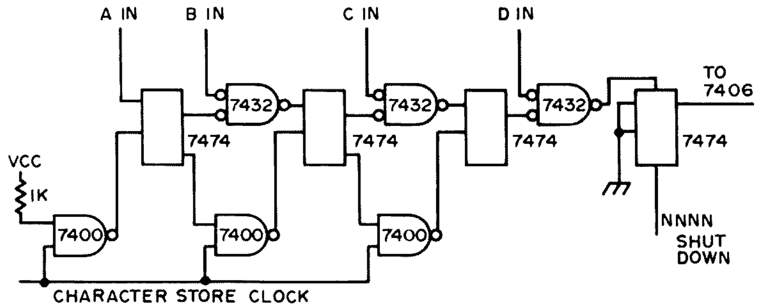

Fig. 6.

output on $\overline{NNN}$; this second shut down is used for a stunt box control.

Stunt Box

I have used a new approach even here. The stunt box version is really just a second printed circuit board that is tacked on top of the CRD. On the stunt box board there are three new and separate character store flip flops. Each "channel" can be programmed completely apart from the others; hence decoded TAPE can turn on a tape perforator, CW ID could start an auto ID unit, etc. With any of the stunt box controls $\overline{NNN}$ shuts down all stunt relays but will leave the printer still going.

Power Supply

Power supply requirements are very low – 5 volts at about 500 mA regulated and 24 volts unregulated are just about all that need be said. An LM309 5 volt regulator is a good bet for the 5 volt line.

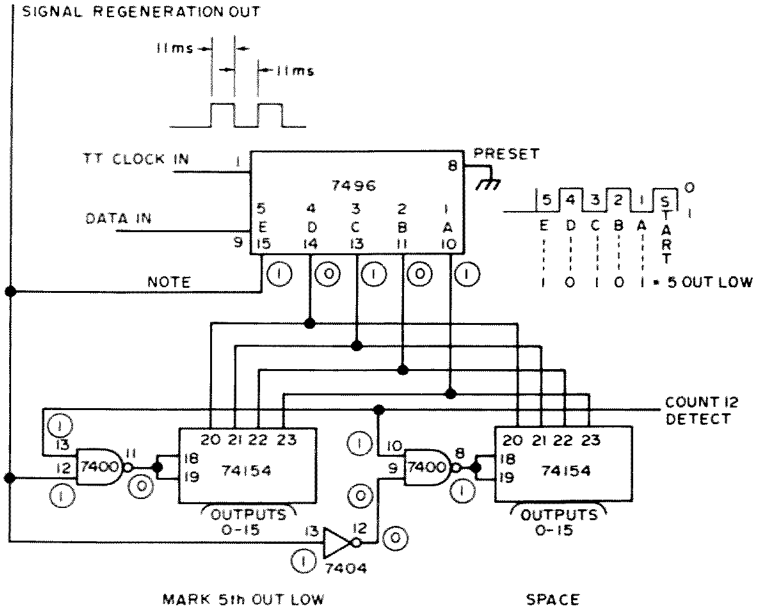

Fig. 7. Regenerative repeater.

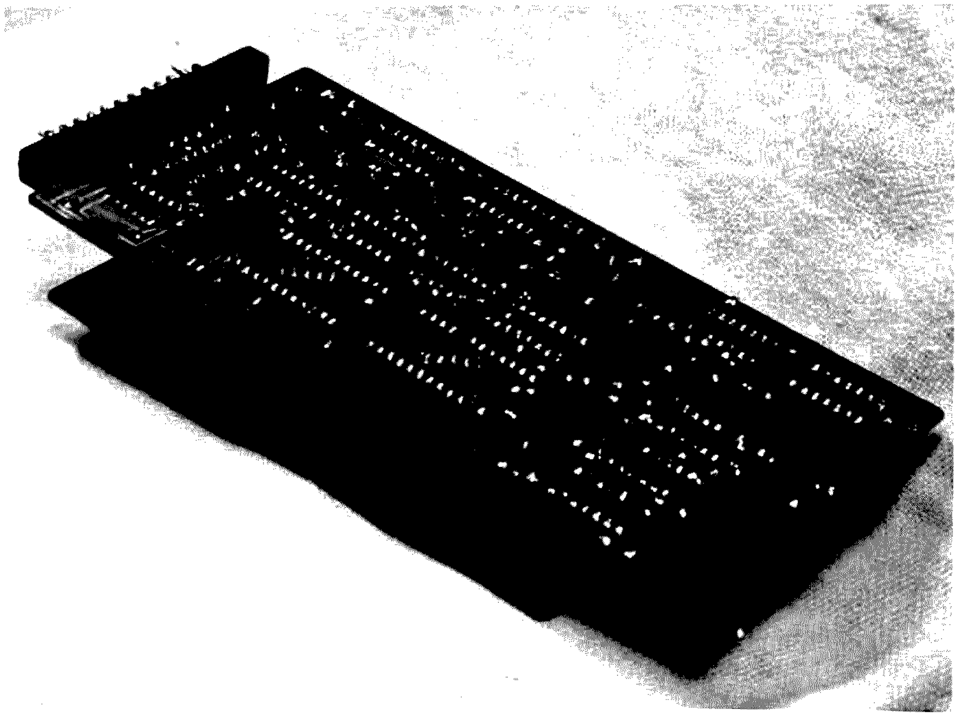
Station Integration

Operation and interfacing into a modern or not so modern RTTY station is best described as easy. Fig. 3 is a suggested hookup. The most desirable results will be found in the stations using one of Hoff's demodulators, ST6 TTL, TTL/2. These demodulators have an auto print section in them that turns on before the Selcal will receive any TTY data in. This makes for greater immunity to unwanted turn ons. One feature not talked about too much is signal regeneration. This is something that all amateur operators should make full use of, as our keyboards are often somewhat less than perfect. Signal regeneration is built into the CRD; by bringing a lead out from pin 15, U8, a correctly timed signal is available for transmission. As information is shifted through the shift register U8 by a local clock which is running at a pulse repetition rate of

Operation and interfacing into a modern or not so modern RTTY station is best described as easy . . .



Mother board with stunt box board, bottom view.

22 ms, a bias-free signal is present at this pin. The station hookup shows how to use this regenerated output to the best advantage.

Uses

This CRD could be teamed with a simple phase locked loop demodulator for a real good 2 meter repeater control system. First thing that crosses my mind is to turn heat on in the winter and off in the summer. You think of a few more.

Conclusion

Printed circuit boards and board layouts are available from the author for those who might need them.

The printed circuit boards that I have are about 3¼" x 7". This is the mother board; it has an edge connector on it for a 12 pin connector.

The stunt box board is just a bit smaller; its size is 3" x 6", and it fits nicely into an ST6 (Hal type); you just might remove the wide shift boards and place the CRD in there.

One thing that just might happen is, your call may contain two identical letters, e.g., 6AII. Normally you would decode letters A, I, I; however, you would find that your CRD would trip on the first I. This could be fixed by moving decode to Y or 6 letters A, I. This would give you a four character decode once again, but if others in your area have calls Y or 6, letters A, I (A through Z), your machine would trip off when that combination came along (most unwanted). So a change in clock signals is needed. One way, as yet untried, is shown in Fig. 6.

This circuit will clock the 7474 flip flops in sequence and should eliminate the problem of a turn on with I, I.

I would like at this time to thank Cal W9ZTK for an idea and the rest of the fellows that are on the WestCan Autostart frequency of 3632.50 MHz. ■

Parts Needed for the CRD

1.5k Ohms ½ Watt	1 only
470 Ohms ½ Watt	1 only
25k potentiometers	2 only
5 volt zener diode	1 only

I/O

Believe Me - I'm No Expert!

by
Wayne Green W2NSD/1
Peterborough NH 03458

Just in case any *73* readers are laboring under the impression that I know a whole lot about computers, minicomputers, or even microcomputers, let me put that delusion to rest. I know more about Arabian horses than I do microprocessors (uPs), and I am not a known expert on Arabians.

Before writing about microprocessors I wanted to clear the air and make sure that in this field, at least for the time being, I am a reporter, not an expert. Hell, I'm not even an advanced amateur yet, but give me time . . . I'll get there.

After talking with the Sphere, MITS and Southwest Tech people during a hurried excursion out west, I got the distinct impression that, from the viewpoint of the user, the differences between the various microprocessors are mostly academic and that from an application view one will do pretty much what another will. Thus, whether you settle on a 6800 system, an 8080 system, a PACE, or whatever, most of your computer time will be spent waiting for the operator, not for the machinery.

Prototype of the Sphere 6800 system.

Until my visit to the manufacturers, I hadn't realized how very early we really are in the history of personal computers . . . and particularly in microcomputers. Sphere had, in early August, one breadboard system running – but still with some glitches to be worked out. They had some program material worked out which they would then adapt to their system, eventually to be available in a 1K PROM.

MITS had their 8800 up and running, but the floppy disk system was still in development, and I gathered that the only bulk storage in use at the time was from cassette tape. Any computer system for business or for much game playing will need at least a floppy disk system.

Southwest Tech had a breadboard system going too, perhaps just a little bit further along than Sphere. I suspect that these systems have had a lot of help from Motorola.

The Sphere group is working diligently on many areas of development, with most of the work being done by a couple of the fellows. They were setting up their production facility, getting the glitches out of the prototype, getting the loader PROM ready, working on another PROM for BASIC, getting started on a floppy disk system complete with an assembler, editor and operating system called FDOS.

They also were working on a system which they claimed would be faster than a floppy, a quarter inch tape using eight tracks at 1600 bpi in a self-loading cartridge. One tape would have as much memory as 120 disks . . . about 30 megabytes . . . and the system would hopefully cost around $3000 including the controller and software. Next they had in mind a jig which would automate the plugging in of the cartridges. A set of five in one system would then permit 1500 megabytes of storage! That's

Mike Wise, President of Sphere, showing the complete microprocessor system.

1.5 gigabytes (pronounced jigabytes). This would run under $7000 for the basic system. It's exciting to think about. The maximum access time for a cartridge would be 20 seconds, which would put the average time at 10 seconds for random access.

Mike Wise at Sphere put me onto a firm that makes cassette drives which are ideal for computer use . . . solenoid controlled . . . and at a very reasonable price. A small system using a couple of these could be set up to run mailing lists and other indexed data. This would be great for the hobbyist who wants to make a little money on the side keeping small mailing lists . . . club membership records, etc. Or

it would be fine for the hobbyist who would like to get into business in a small way selling relatively inexpensive computer systems for small businesses. I have a feeling that we will see a lot of program development for systems like this when the hardware is available.

I suspect that the whole field of programming is going to change significantly with the introduction of relatively low cost computer systems. Where before only large businesses could afford systems, now they will be everywhere and there will be thousands of people working up programs, not dozens.

Small systems will grow as rapidly as we are able to get them running with I/O devices and memory storage devices. *73* wants to hear all it can on these developments so they can be fed back to everyone in the field. Let's have user information on interconnecting the television typewriters to the Altair 8800, the Altair 680, the Sphere, the SWTPC 6800, the Godbout PACE, etc. Ditto Teletypewriters, used tape drives, used line printers, surplus keyboards, cassette recorders, floppy disk systems, etc.

There are some exciting developments coming along in mag tape systems which are a bit high for the hobbyist, yet are great for the small business ... let's be sure to write about these ... how to look them up ... operating systems, etc.

The idea of using a PROM systems software is a good one. I suspect that this will take hold. The Sphere idea of a PROM containing an executive, I/O driver, I/O for cassette, and I/O for a video terminal may take hold too. Sphere was talking about converting source language to machine language with a PROM, converting serial to parallel ditto, etc.

MITS

My talk with Ed Roberts, prexy of MITS, was most interesting. Rather than go it verbatim, I'll engistify it for you.

I asked Ed how MITS got into the microprocessor biz and this got him going in good shape. It seems that the term microcomputer was probably originated by the editor of EDN and the micro part of it has no relationship to the power, word size or the speed of the computer involved, just the large scale integration (LSI) of the IC involved.

Before getting into the 8080 based system, MITS looked over the market to see what was available. The IMP-16, a 16-bit machine, benchmarked a couple orders of magnitude slower than the 8-bit machines, so they decided not to go that route. Actually, according to Roberts, the 8080 is not an 8-bit machine, but a 24-bit variable word length machine that has an 8-bit arithmetic logic unit (ALU) and can directly address 65,000 bytes.

At the time of the decision to go 8080 there were only four other serious possibilities ... the 8008, the 4004, the IMP-8 and the IMP-16. Since the IMPs seemed very complicated and to need a lot of external hardware, it came down to the Intel chips. They almost went for the 8008, but the nod went to the 8080 after they added up the figures ... the 8080 is about 10 times as fast as the 8008 and only costs twice as much, leaving a 5X benefit. MITS spent about eight months evaluating the systems.

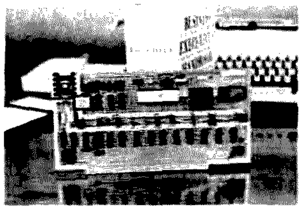
The M6800 came along later and seems to have some advantages for smaller systems – according to Roberts, the I/O structure of the 8080 is better for bigger systems. The PACE seemed to be slower than the 6800 or the 8080 and it is limited to seven or nine subroutines. MITS felt that a 16-bit machine would have a difficult time competing with a 24-bit machine. If the PACE had been significantly lower in cost, that might have been a factor.

Whither Time Sharing?

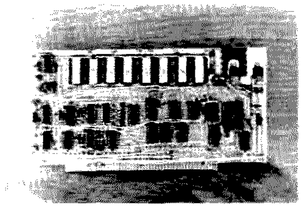
Ed opined that time sharing is going to die. The data transfer rate is just too slow ... limited to about 30 characters per second (cps). And when you consider the cost of time sharing, with rates running from $5 to $7 per hour (MITS charges $2 per hour), you probably can buy a complete micro system cheaper than several months of that. Once ROM program chips are available you won't need any experts – when the power is turned on the ROM will provide the program to have the computer go to track zero on the floppy disk and load the operating program.

One problem is that as more microprocessor chips are developed this will result in the need for more hardware to be developed and, worse, more software. If the field settles in with the 6800 and the 8080 we may get a chance to develop a large number of sophisticated programs for use with these machines. If more and more microprocessor designs proliferate it could split the field so that much less is developed. The second sourcing of the 8080 by Texas Instrument and Advanced Micro Devices (third sourcing?), and the AMI second sourcing of the 6800, as well as the MOS Technology 6501, mean that these multisourced microprocessors will have a big head start over other uPs. The 8080 got a good lead by virtue of the head start of microprocessor innovator Intel.

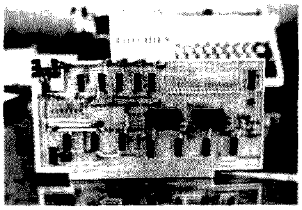
MITS had no serious problem in deciding to



MITS 8080 CPU board.

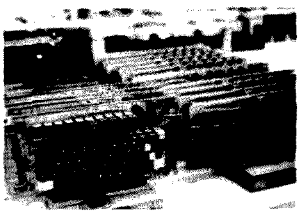


Altair 4K dynamic memory board.



Altair serial I/O board for cassettes.

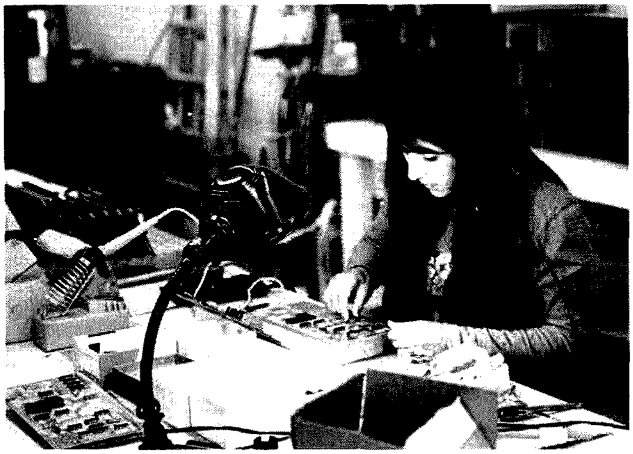
MITS work area with Altairs abuilding.



Production run of MITS keyboards.

accommodate the 6800 ... the Altair 680 backplane is exactly the same as the 8800 except for the CPU card ... and it plugs into the Altair bus.

The 6800 has two accumulators, an index register, and a stack pointer on the chip, but no general purpose registers. There is a short instruction format to access the first 256 bytes of



Wiring an Altair board.

memory conveniently as a general purpose scratch data area. With the 8080, there is one accumulator, a stack pointer and six registers which are paired for use as pointer registers. These are often used as if they were general purpose registers, which is handy since the 8080 cannot reference memory addresses directly for most instructions.

What major problems has MITS had? Delivery has been about the only problem, but it has been a big one. At the time they started making deliveries of the 8800 they had 24 people . . . now they have 85 . . . and it takes time to find and integrate new people into a company. No department can handle more than one or at the most two new people at a time and function well, so this severely limits the speed with which a firm can safely grow.

The Altair clicked none too soon. MITS had been heavily dedicated to the calculator field and joined all the others in taking a terrible bath when calculator prices dropped off the end of the dock. The firm lost about $200,000 in 1974 and things looked very bleak by the time the Altair was announced. It was a tremendous gamble for no one knew for sure whether there even was a market for a microcomputer . . . particularly one in kit form. It turned out that there was indeed a market and well over 5000 8800s have been shipped so far . . . about 60% of them kits, and about 50% to hobbyists and 50% to OEMS.

Ed had some glowing things to say about Altair BASIC. The Altair BASIC interpreter was developed jointly by MITS's software wizards Bill Gates, Paul Allen and Monte Davidoff – who are now busily working on an extended BASIC and other packages. (It turns out that most systems software packages such as Altair BASIC are designed by individuals and implemented by at most two or three people as was the case here.) The 8K Altair BASIC, claims Ed, outperforms just about any other BASIC going. A week spent with BASIC and you will be in shape to write some pretty good programs. The nicest thing about BASIC is that there are many programs in print in the innumerable books on this language.

I asked about the possibilities of hobbyists using some of the cast off computer peripherals which are around fairly reasonably from used computer firms. Ed blanched. If a big disk drive is inexpensive you can look for big troubles . . . big expensive troubles . . . then there is the matter of working up an operating system, a detail which could take an enormous amount of time. This might be practical for someone with a lot of experience and all the time in the world. The larger tape drives could back you into the same corner.

Stuff which is RS-232 oriented would be fine, such as line printers, Teletypes and video display units. The chances are that you won't be finding all that many VDTs on the bargain counters. Paper tape readers might be a good deal.

This brought us down to some discussion of larger memories . . . the soon to be released MITS floppy disk system . . . and some other memory storage schemes that are in the works. For instance, there is a new ¼" eight track tape cartridge that may be as fast as a floppy. It will search at 240 inches per second. It will also read and write at this speed, but the inter-record gaps are wasteful and they figure to read and write at 62½ ips since the read and write time is trivial to the search time . . . you search by counting the gaps between records. One cartridge can hold 14 megabytes unformatted and about 8 megabytes formatted.

Games

The discussion got around to computer games and Ed mentioned the lunar landing game wherein you have to try to land on the moon with zero downward speed . . . it took him the best part of a night to get the hang of the very non-linear problem involved. Star Trek is another game which fascinates just about everyone who gets involved with it . . . it is quite sophisticated and intricate. I asked about chess . . . he said he would try to get a copy of the Data General chess game . . . supposed to be the second best computer chess program available . . . but not much of a challenge for any serious intermediate or higher level chess player.

In all it was a most interesting visit . . . I learned a lot . . . and let there be no mistake that I still have a great deal to learn before I will know enough to even read the computer literature and understand it. I would like to let any readers who might be feeling a bit edgy about the more technically oriented articles in *73* know that in time you and I will understand what is going on . . . we may even be able to talk computers with both hardware and software pros.

SWT

The third stop on my microprocessor tour was Southwest Technical Products in San Antonio. Actually this was just a very lucky coincidence, for I went there to see them in regard to their television typewriter unit which is a natural to go with computer systems as well as amateur teletype.

Dan Meyer, the president, and Gary Kay, the chief engineer, spent the day showing me their new

Dan Meyer, President of Southwest Technical Products Company.

6800-based microcomputer system which is due to be released soon in kit form. They had a prototype system set up and working and it certainly was impressive. I asked a lot of questions, trying not to make my abysmal ignorance of microprocessors too evident.

For instance, I asked how come they went with the 6800 chip for their system instead of the several others available.

8080 vs 6800

While I figure it will be quite a while before the proponents of each chip will be cool enough to sit down and work out a comparative evaluation of the situation, this has not stopped me from asking the participants to give me their reasons for going one route or the other.

Gary Kay, the computer engineering brains at Southwest Tech, tried to explain the differences between the two chips to me and why he decided to go with the Motorola 6800. I understood things here and there, aware of a need for a better interface for dealing with people who speak in computerese.

Well, it seems that Gary looked into everything available . . . went to courses provided by the chip manufacturers . . . read a lot . . . and it all came down to the 6800 for him. It was much easier to interface than the 8080 . . . required fewer external parts since much of the work is done by software instead of hardware. This need for fewer parts would seem to be demonstrated by the substantially lower cost of 6800 based units vs. 8080 units (the MITS 6800 based unit is $293 vs. $439 for the 8080 kit).

With the 6800 you can set up any of the 16 lines for input or output and change anytime you want just by programming instructions . . . even in the middle of a program. You can program the system to give any priority for a particular input device. You can do a lot of things with programming that have to be done by switching with the 8080. You can even program whether it will work on a positive or negative strobe (if you are). The handshake line . . . lets it be known when data has been received . . . is all right there on the chip. The 6800 was designed as a system and thus takes less outside equipment to get it working.

Another plus is the Motorola supplied MIKBUG, a small operating system which is available on a ROM chip. This is a nice feature which can be appreciated by 8080 users who find they have to start out by hand switching in about twenty steps before the system will be able to accept programming from tape or cassettes . . . or even a keyboard. Thus, with the 6800 systems you can just flick on the power switch and the initial programming is all done by the built-in read only memory and you find a snowflake blinking at you on your screen indicating the system is ready for use.

This elimination for the necessity of hand switching in the loading program has made it possible to do away with the usual computer front panel and its row of switches and rows of LEDs. Further instructions to the system can be put in by means of a keyboard using octal or hexadecimal notation, whichever has been programmed in by the ROM . . . hexadecimal in the case of MIKBUG.

As time passes we will see whether the 8080 or the 6800 systems have more for the users . . . and that is the bottom line.

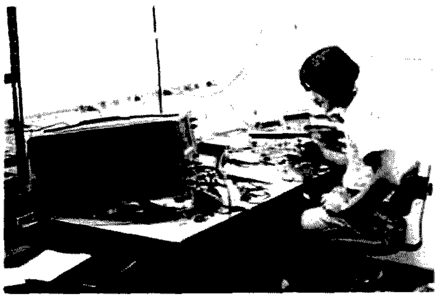
The Southwest Tech 6800 kit sells for $450 and includes some handy items. There is

Sumptuous SWTPC front office.

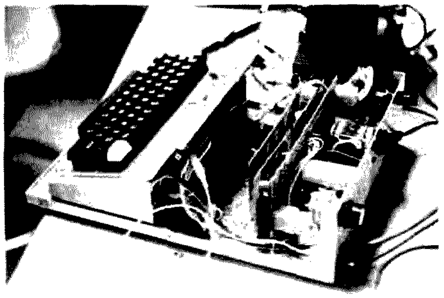
Silk screening front panels for SWTPC kits.

Kit assembly area at SWT.

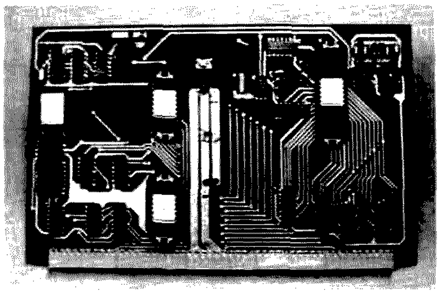
Parts picking for SWT hi-fi kits.



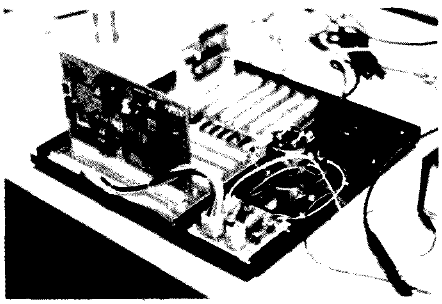
Service area – when the kit builder needs help.



SWT television typewriter . . . being used an an I/O for their new computer kit.



M6800 CPU board, part of the SWT kit.



Prototype of the SWT 6800 computer kit.

Gary Kay, the chief engineer of the computer project.

the mother board into which the processor, memory and I/O boards plug, a chassis and cover, power supply, the processor board with the 6800 chip, ROM MIKBUG, 128 bytes of RAM and a clock for the system, and a board with a serial input/output for teletype or RS-232 such as the CT-1204 terminal. A 4K memory board is also included which has 2K on it and space for plugging in 2K more to fill out the 4K . . . the extra 2K is available for only $45. The result is that you have a complete computer system for $450.

In addition to the 6800 kit you'll need to have some sort of I/O device, probably either a teletype with ASCII output or a TV video system such as the CT-1024 kit and a TV set. You'll need more memory for any practical computer operating system . . . certainly the extra 2K and more probably a total of 8K. You will need some sort of bulk memory system such as a cassette recorder and an I/O board which will interface it to the system. Floppy disk systems are nice, but they are still too expensive for most hobby systems and the programs to operate them have yet to be written.

The Southwest Technical operation is a beauty to behold. They are using a Datapoint computer system to run the whole works. The sales are 100% mail order and each order is entered in the computer as it is received. A label and packing slip is printed out for each order and an acknowledgement sent out automatically. Each week all orders are processed by the system and inventory records updated to account for every resistor and part used in the kits. Delivery schedules are in the system too, so when parts in stock get below a quantity which might cause them to run out the computer initiates an order for the parts. Since this system was set up there have been no delays in filling orders due to out of stock parts!

Questions on orders can be quickly resolved by searching the computer memory for the name, zip, or even the ordered kit. Everything is right there at hand.

Dan Meyer, the president of Southwest Tech, took me for a tour of the plant . . . it was enormous. The printing department is bigger than the *73* printery which turns out the many *73* books . . . acres of space filled with shelves of parts, people putting kits together, and more cartons that you would believe. The company has built up a good name in the hi-fi field where it is one of the largest of the kit manufacturers and known for the high quality of their units.

The first excursion into ham territory was with their television typewriter kit . . . a natural for RTTY operators. The CT-1024 terminal system, first made known in a nice article in *Popular Electronics*, consisted of a character generator, sync and timing circuits, cursor, 1024 byte memory . . . all you need to put a 16 line message on the screen of a television set with a video jack on it. The 1024 byte memory is enough for two pages on the screen and the unit automatically switches from one page to the next when the bottom of a page is reached. This kit sells for $175 and is very simple to put together. My twelve year old daughter helped with a good deal of the assembly and soldering of my kit.

A power supply for the unit is available for $15.50 more, as is a keyboard for about $40 and an output interface to feed ASCII to your RTTY system or to a computer ($40). Thus, for about $275 you have a complete system, requiring only an old black and white TV set for a display and an RTTY system geared to ASCII input (RS-232). Compared to today's teletype machine prices, that has to be one of the best bargains going. Compared to commercial video display keyboards it also was an outstanding buy.

The SWTPC 6800 computer kit looks like a winner, too. Priced at $450, it includes a 714 page applications manual, the 6800 chip, the MIKBUG ROM operating system, a serial interface which will operate a 20 mA teletype or work with their TV typewriter system. ■

Poughkeepsie NY 12603

Night DXing on 10 and 15

Talk about a rat race. If the 40 and 80 meter bands aren't a rat race after 9 PM, then what is? If you're like me, tired of foreign AM broadcasts on 40, or 80 with its 50 kHz of pileups, read on. The closest comparison to 80 at night is a Martian ham station calling CQ DX on 20 on a Saturday morning, only more so.

Getting back to 10 and 15 night DXing: It isn't really DX, but it has all of its rewards. It sounds like DX, is just as thrilling (for me anyway) and boy it's a big band or two and nice and quiet. Talk about QRM free, here it is.

Working a fellow novice, or anyone who happens to be "slumming" on 10 or 15 at night is just great. There's the QSB of DX as the ground waves fades. There's that low lonely signal to pull out of the mud; who cares if he's only 50 miles away? It's just as hard, if not harder than any DX you ever work. And I mean pulling him out of the mud, for he's as subterranean as you can get. But that's where the thrills come in. The accomplishment of the above feat is equal to working any DX. He sounds like he's in Asia, so who cares if he's fifty miles away?

I've been a Novice for about nine months now, and have worked my share of DX. For the most part, when it's in, it's in, but when it's out, forget it. There's rarely any sweat working G's, I's, ON's, etc. when they're 469 or so. Compare these sigs to the guy 229 fifty miles away and you're getting the idea.

Living within Metropolitan New York City, I'm sure that more than a few hams can CQ on 10 or 15 at 10 PM nightly. Just think, a total of 200 kHz of quiet to work with.

I guess for the most part a great many Novices tune 10 and 15 for a few minutes at night, they hear nothing, and go to war on 80. However, I'm almost certain that if a bunch of Novices start calling CQ on that virtually dead band, something will start.

By the way, I've listened to 15 meters from 9-11 PM EST at times, and lo and behold out of nowhere, on a seemingly dead band, "CQ CQ CQ DE ZL1A ..." So, my fellow hams, if you've got those PM blues like me, let's get with it. Anyone within 100 miles of my QTH drop me a line and we'll try and sked. All you others try some 10 and 15 meter Nocturnal DX. You'll be just as excited as when working a real one. If not, there's always girls. ■

60 Hurts Per Second

I sometimes wonder about the history of hams — everybody knows that amateurs have been responsible for technical advances in radio. But I can't put this into perspective when I think of my own work. Like the first project I ever built. It was a 30-watt peanut whistle from the Handbook. I thought I was doing something just barely removed from basic research — at least until I got to the parts supply house.

The guy behind the counter had the gall to tell me that the 5U4 could be replaced by this new tube — it was a 5AR4 — and it was smaller, more efficient, and cheaper, too! So I dropped my self-esteem a tiny bit and took it home to start work. My high school radio club advisor suggested I scrap it for a few silicon diodes. Well, he was a physics teacher, and everybody knows that they know all about these modern techniques. I used the tube — but I started to play with them "solid state" devices that were suddenly everywhere in radio.

I was pretty sure of how to use silicon and the old-fashioned seleniums when I took that junior college course called "Tubes and Transistors 109." I signed up thinking that we would be used as consultants to the guys at RCA when they needed some help. But that course ... I showed up for lectures that sounded more like a karate demonstration in a Greek restaurant. Imagine walking into a room and hearing "Hfe Hie Beta Fco Alpha." What the heck was he talking about?

I got through the course. I can't say that I got an A, but I was finally up on the latest. So there I was — I knew the latest terminology from the industry and could do real up-to-date work. So who asked for help from ARRL-FCC? Why couldn't they leave well enough alone? HERTZ, indeed! No offence, Heinrich, but I still say cycles per second. At least until I get my fingers across the a.c. line, at which time I get 60 hurts per second.

So our hero (that's me, ace wizard-experimenter-researcher) strives to help the world move ahead by applying this wonderful knowledge of up-to-date electronics. I was thinking of something along the line of miniaturization. I stopped at the familiar

parts house to get some reference works ... and saw books about the new integrated circuits. One fellow must have thought like me, though. His electronic device was dubbed the ICKEY. My feeling, exactly.

I was not stopped by the move to "small," though. Even though my head was turned by stone-crushers running 3-phase 208 through the primaries more than it was by those tiny transceivers Al Kahn was making, I thought about trying QRP. I did, and it worked fairly well. I used a borrowed HW-7 and made one contact on 40. He was about 4 miles away, and still insists that he did hear me that day. We used 2m FM for liaison. The antenna, of course, wasn't the best — hookup wire wrapped around the copper heating pipe for about twenty feet before it led outside where it paralleled the gutter. But I had heard that these little rigs didn't need much of an antenna, and anyway, I was using a transmatch. I could set the thing, though, since my SWR bridge would work with that ridiculously small amount of power, but I did arrange the taps so that they looked pretty, and that should have been enough...

QRP having proved nothing, I went back to my plans for giving RF burns to all within miles of the main lobe. I went through my usual process of modernization, going from the old glass 4-400A to a couple of 4X150's to the ceramic 4CX250A to the ultimate — a 4CX1000A with only about 15,000 hours on it. The engineer from the local FM station said it had been taken out of service as regular maintenance — not for any defects in operation, although it wasn't quite as perky as when it was new. After scraping the corrosion and smoke from the tube I settled down to build. I even secured that one thing that *NO* high-power rig can go without — a forty horsepower wind generator from Hollywood. I figured that would provide my state of the art amplifier with sufficient cooling air to take care of all possible eventualities.

Apologies for the little break, but I just got the mail, and I took a break to read the ham magazine that came. I see a high-power amplifier is shown inside. That just might be what I needed — a chance to compare notes with the author, and maybe give him a hand with design modification. Funny looking circuit, though. I don't see the fan to cool the final. Hey! What's CONDUCTION COOLING? ■

Catch Big Ones - Fishpole Mobile

by
Joe Rice W4RHZ
916 Western Ave
Covington KY 41011

After investigating the available "store-bought" mobile antennas and looking at their prices, I came away more than chagrined. Not only were the prices high, but equally important the swr was poor, indicating a sort of compromise in design.

I decided to build my own. Having already done reasonable experimenting on other bands, I decided I would like to try mobile CW on 20. On lower bands, such as 80 and 40 and even on 160, the efficiency of mobile antennas falls off sharply. 80 meters still had an appeal for me but I decided 20 was better because of the skip conditions. Incidentally the whole rig was built using an old 1625 tube driven by two type 6F6s as buffer and driver. The vfo was home built using three transistors operating on 40 meters and mounted in the front of the car.

As no one has really resolved whether center loading or base loading is the best, I decided to use a little of both. The general philosophy was to make the center loading less than optimum and augment this with the correct amount of inductance in the base to bring the system into resonance.

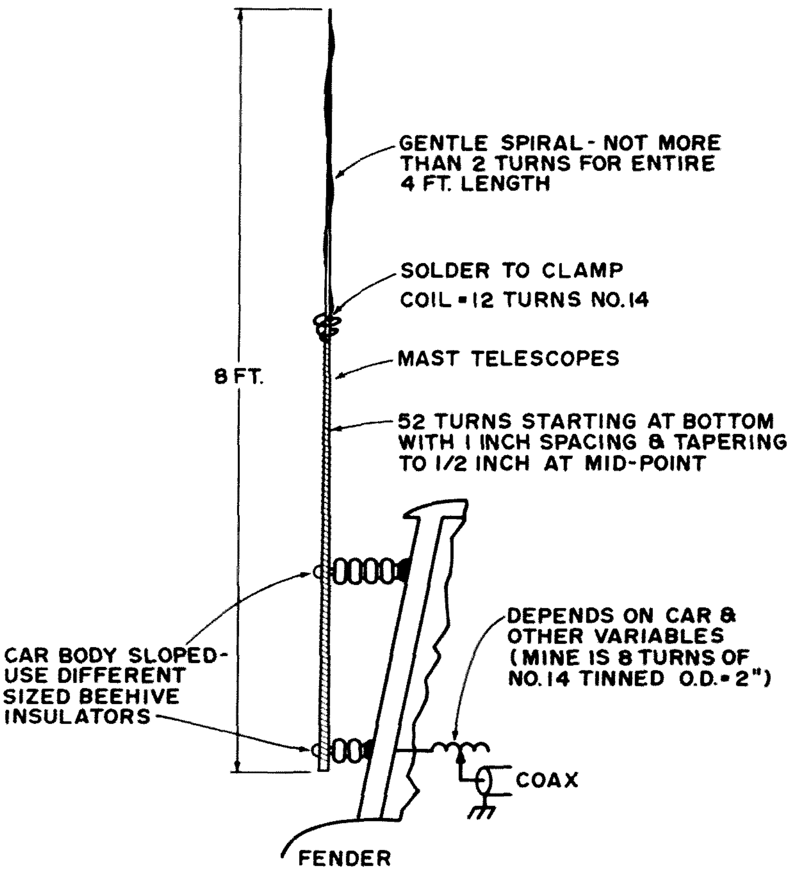
Bamboo is hard to obtain these days, for some reason, but I did find a three-section fishing pole at the nearest hardware store which was small in diameter and had a lot of give to it. I decided to use the old-fashioned beehive standoff insulators to hold the antenna away from the car body. I had some compunction in using the ceramic as I first thought it was far too fragile for mobile use. It has proven to be very durable. I even whacked a few tree limbs on purpose at a reasonable speed of 30 mph with no ill effects.

The fishing pole comes in three sections, each fitted with a brass fitting so as to telescope into the mating section. I only used two sections making an overall height of 8 feet. To obtain greater efficiency, I wrapped number 16 wire around the bottom section to get the inductance up. The center coil was mounted on two aluminum clamps bolted around the bamboo. I used a soldering lug in order to solder the coil directly to the pole. The top section of bamboo has another piece of number 16 stretched to the top with just a gentle curl around the pole. This is done so that the wire will not break if you should hit a tree limb. If the wire was stretched out straight, it would bend in such a manner as to break.

When I first grid-dipped the whole affair it dipped in the 27 MHz band! It would seem that the grid dip meter only sees the overall height of the antenna, sans any coil at all. Another dip was found nearer the 14 MHz region.

The insulators were mounted using self-tapping steel screws and a piece of cork gasket material between the car body and the insulator to take up the shock. I put varnish around the whole thing later to keep moisture out.

The photo and diagram tell the whole tale. What is not shown is the feed system. I tried every system in the mobile handbook to no avail. In desperation I used a piece of coax cut to the right length so as to look like a quarter-wave transformer. Like most amateur radio operators I do not have the facilities to measure the radiation resistance presented at the base of an antenna. An educated guess told me it was in the general neighborhood of about 20 Ohms. Using a piece of RG 58U cut to a length of 10½ feet, it yielded an swr of about 2:1. Anyway, it works! Since the center loading coil is mounted on the top section, I can easily change it to operate on each band. The entire 12 foot, 3-section pole only costs $1.39 and is apparently tougher than any man-made material. ■



Glitchgate

by
George M. Ewing WA8WTE
510 Sheridan Drive
Sault Ste. Marie MI 49783

We had been out at John Gregory's house for several hours, working on an old Russian samovar that his mother had brought back from the Turkish highlands near Adana while on a DXpedition in the Middle East. We couldn't seem to keep the charcoal lighted and were thinking of forgetting the tea and using the silver hot water tank for a coaxial tank filter for the backup receiver on VE3SSM. Suddenly we realized that it was after eleven, and that there was no beer in the house. It was definitely time for a break anyway, so John and I fired up Supertruck and trundled on down to the Antlers Bar & Grill.

When we got there, our usual seat under the Chippewa war canoe had been taken by some boisterous hockey fans, so we settled for a corner table between the stuffed boa constrictor with the snowmobile helmet and the Eire flag. The snake is a regular patron of the Antlers, and on St. Patrick's Day has been known to slither down the bar and drink green beer from the customers' glasses if they aren't too alert to snatch them away.

At any rate, after John and I had ordered our Paul Bunyan Burgers and drafts, we resumed a previous discussion, something about Middle East Politics and Long Delay Echoes. Some of the people from Harvey's basement came in, swiped some chairs from the table on the left of the stuffed moose's ass, and joined the group. This perforce changed the thrust of the discussion to such technical niceties as the superiority of non-volatile ferroelectric memories over ECL and the advantages of sapphire as a substrate material.

Frank Ostrander and some of his FAA buddies came in, and took the other adjacent table, under the steam whistles. Frank's a ham, but he's not into semiconductors much, so the conversation gradually shifted to weather and flying stories.

John Gregory started us off by telling the one about Dick White, a VHF nut and pilot who had been stationed at Kincheloe Air Force Base. Dick had been flying a mission out over Lake Superior one spring evening when he got a U.F.O. from the boys at the 753rd AC&W radar station, and was ordered to investigate. When he arrived at the target area, he reported that he saw a 213m (700') long spaceship with rows of lights along its sides. He was tracking the thing so intently that he forgot his instruments, followed the image through a temperature inversion, and found himself in a screaming Kamikaze dive at the Wilfred Sykes, a lake freighter on Whitefish Bay. He pulled out in time, and after an embarrassing hour's debriefing, went home, fired up the 432 rig, and got three more states and Manitoba before the opening died.

He was tracking the thing so intently that he forgot his instruments and found himself in a screaming Kamikaze dive . . .

Drawing by Neal Kandel

Bill Rennamaki and Mike Daniels came in about then and joined the group. They swiped two more chairs from over by the Fokker Triplane propeller with a stuffed dog on it, and ordered another round. Mike's a radio astronomer for NASA out at North Liberty IA, and told several solar flare and LDE jokes.

John Michael retaliated with another U.F.O. story, this time about one that WE launched. This particular one had been 30m (100') plastic film hot air balloon supported by a peanut butter pail full of burning gasoline. It had been a real beauty, with tuned radar reflectors, strobe lights, and a scrounge TACAN transponder on it to confuse the Air Force. John Michael had burned his fingers lighting the gas, and henceforth claimed that he was one of the few verifiable U.F.O. casualties.

After a few more flying stories and a halfway serious proposal for a high altitude balloon repeater for emergency coverage during disaster that was shouted down, at least for the U.S. side of the river because of licensing problems, we saw an old friend come in: Frankie Leitenen, the tool and parts king of the Northern Michigan hamfest flea markets. Frankie had started to take a

table 'way in the back, under the nude autographed portrait of the 1948 Detroit Red Wings in Toivo Crimin's Sauna Bath. We hollered and motioned, and finally he sauntered over, dictating his hamburg order over his shoulder to the waitress.

Everybody was glad to see Frankie. He hadn't been around the Antlers for a couple of years, or at a hamfest for longer than that. We'd missed him, too. He'd always had the best deals on tools, tubes and small components at all the swapshops. I'd bought stuff from him from time to time: an obsolete tube, a roll of Teflon tape, or a handful of ICs that I needed for the latest project. You just couldn't beat his prices, and at least at first, he had always been willing to take your junk in trade, even some pretty unlikely stuff. We had always wondered where he'd gotten all that junk, and when he sort of disappeared, there had been a good deal of speculation that he'd gotten in trouble with the military for scrounging too handily at surplus disposal depots, or been the subject of an IRS witch hunt.

He seemed cheerful enough now, though, and if he'd had a run in with the Mafia or Uncle Sam it hadn't left any outward scars. He did seem to be looking over his shoulder a lot, though. As soon as Trixie, the waitress, had brought his Paul Bunyan and tied the bib with the shamrocks on it around his neck, he was bombarded with questions. He was non-committal at first, but then the question was put more bluntly:

"Why the hell aren't you at the swap-and-shops any more, Frankie, you been in jail or something?"

He made the old familiar empty pockets gesture, from the horse-trading days, and said something to the effect that he'd love to buy a couple of pitchers of beer for the gang and tell us all about it, but that he had payments to make on his new triggered-sweep scope. Also, he was low on beer money and, anyway, we'd scoff and wouldn't believe him.

Well, this was a pretty obvious come-on, but I reckoned that a good story was worth the price of a couple of 807s. Several others agreed. A small but impressive pile of bills and change appeared on the table, and we were giving Trixie our orders when some fool hockey fan down by the Samurai swords ordered a steak.

Perhaps I'd better insert a parenthetical note at this point. All the gongs whistles, bagpipes, air raid sirens and other junk on the walls of the Antlers are functional, and *loud* to boot. When a steak order comes in from the teletype terminal by the meat case, two or three demented bartenders run up and down the bar, pushing buttons, stomping pedals and swinging bung-starters. All hell breaks loose.

When one of my buddies was back in the world from Tay Ninh a couple of years ago, he heard the steak siren for the first time in over a year. He dropped his beer on the floor, made a running dive hollering "INCOMING!" at the top of his lungs, and slithered around under the tables, looking for a bunker.

After the brouhaha had died down, and the steam from the whistles had cleared out so that you could see, Frankie continued as if nothing had happened.

"As I was saying, it all began soon after I bought that old yellow farmhouse out on the Pickford Road. The old couple that lived there thought that the place was haunted, or something, and I got it at a really bargain price. I tried to get some information from them before they piled into their camper and scrammed for Florida, but all I got was a few incoherent mutterings from the wife about 'varmits' and 'toady-frogs.' I moved

Mike interrupted, asking what the glitches were supposed to look like. I told him they were long-nosed, pointy-eared creatures . . .

Frankie went on, describing the battle he had reeling in the recalcitrant little beastie, as big a fish story as any steelhead angler ever told . . .

in the same day, set the workbench up and strung up some antennas."

There was an interruption for a couple of minutes. Somebody at the next table had left a silver dollar as a tip for Trixie and it had disappeared before he had even left the table. He stalked angrily around the room, peering under tables and chairs. His buddy tried to console him, telling him that it wasn't really silver anyway, only an Eisenhower slug. But he was still angry when he finally walked out.

Frankie continued, "I spent the next few days sorting my junk, which didn't really amount to a lot in those days. I kept my eyes peeled for the varmits the old lady had mentioned, but without success. I did glimpse something scurrying around out of the corner of my eye a couple of times.

"After a while though, things started to disappear: small tools, hardware, transistors, that sort of thing. At first, I thought I was just being careless, but one night an expensive UHF power transistor vanished from the middle of a perfectly clean bench. I spent about an hour going over the floor, table, the works with a Tensor lamp and a magnifying glass – nothing.

"I took a few minutes break, and got a Coke out of the cooler upstairs. When I returned, the transistor was still gone, but there were several lockwashers and an unmarked TO-5 case with six leads lying on the same spot on the bench."

"Packrats," said somebody at the next table.

"No, gentlemen," said Frank. "I had been convinced that I was dealing with glitches."

Well, this got a good laugh, and several members of the group, taking this to be the punch line of Frankie's story, started to tell about *their* adventures with the glitches. Frankie was far from finished, however, and he tore into the scoffers with an almost missionary zeal. I was skeptical, of course, but not so much as you might think. I had mislaid tools and parts over the years, sometimes returning to find them in plain sight, sometimes not. Then there was the scissors hole at Gregory's house. Over the years, dozens of scissors, tinsnips and wire cutters had disappeared. Only a few of them had turned up, and those had been badly corroded.

Mike interrupted, asking what the glitches were supposed to look like. I told him that they were undoubtedly descendants of the original World War 2 gremlins, and were, therefore, long-nosed, pointy-eared creatures, like the AMC emblem or a cartoon Martian.

Frankie was downright contemptuous. He said that showed how much we knew about glitches, namely zilch. Ostrander, scribbling notes on his placemat, motioned Trixie to bring a couple more pitchers. An Air Force colonel had come in and was listening to the proceedings with a bemused grin. Two strangers with overcoats had followed him in. They were sipping beer under a picture of John Philip Sousa directing the 1924 Sault High School Marching Band.

Frankie continued. "You guys can laugh all you want, but I've seen them, and I have proof that they exist. Once I realized what I was up against, it was only a matter of time before I had a real, tangible glitch. The first thing I did was set up a Polaroid camera and a photocell focused on the spot on the bench. I left some shiny hardware and a handful of 2N706s on the table as bait. Over the next few days, I used up several packs of film, but with disappointing results; they were too fast. Even with 2000 speed film and a one millisecond flash, the pictures were blurry, but there was definitely something there."

Frankie went on, ignoring the hooh-hahs and jeers arising from the last. "I got a few pictures, showing a long, lizard-shaped thing, but nothing that would serve as proof. I lulled their sense of security for a while, feeding them copious amounts of hardware and shorted diodes and zip-tops. Once in a while I'd get something in return. After a while, they hardly paid any attention to me. I discovered that they weren't running across the bench, as I had first imagined, but rather were materializing and vanishing again, all within a meter or so of the center of the workbench. They were completely silent, never making a bang of displaced air, or any of the funny noises that are supposed to accompany poltergeists or supernatural creatures. Finally, I decided to set a trap for them.

"I took a particularly shiny IC case and put a few drops of Eastman 910 on it and bonded on the eyelet from a fishhook. I got a fancy spinning reel, and wound about 91m (100 yards) of Corbollon macromolecule filament, with hundreds of pounds of tensile strength, and nearly invisible. I bonded some scraps of ruby rod from a busted laser onto the reel bail as bearings. Then I hooked up an alarm, sat back and waited.

"I didn't have to wait very long before the alarm rang. The IC vanished, trailing line from a screaming reel. I half expected the line to be bitten off, or to be cut by the edge of the hole, or gate, or discontinuity, or whatever, but it wasn't. I had caught myself a real live glitch; now all I had to do was reel him in."

The colonel had pulled his chair up as close as he could. I recognized him now, an operations officer from Kincheloe. He was

listening intently, every bit as hooked as Frankie's glitch. The Overcoat Boys were squinting their ears so hard they were nearly falling out of their chairs.

Frankie went on, describing the battle he had reeling in the recalcitrant little beastie, as big a fish story as any steelhead angler ever told.

"I finally had him back through the gate and held him down on the bench top. He (I discovered later that he was an adult male) flopped and wiggled a bit, and then calmed down. Pretty soon I could hold him in my hands. He was about 32.8cm (1') long, shaped like a Gila monster or salamander, and surprisingly heavy, like he was made of metal. He was a mottled brown and olive color, with a red place on his throat which he puffed out at me. The IC case was firmly glued to his lower jaw."

There was another interruption for a steak alarm, this time with a couple of blasts on a hockey fan's Freon air horn, and a couple of gunshots, which sent the strangers in the trench coats scurrying for cover behind the meat case in the corner. One of the bleary-eyed snowmobilers started out singing a verse of the engineer's song. A couple of the guys in our group started to join in, but they were promptly shushed. The rest of us were interested in the story and it was getting dangerously close to closing time. I didn't want to get stuck with a cliff-hanger.

"From there on," Frankie continued, "it was easy. I caught several more of the little buggers in roughly the same way and eventually trained them to retrieve more tools and parts than they stole. Some of it was pretty weird, but enough of it was salable to make a handsome second income for several years. I fitted 'em out with little stainless steel collars, like cormorants. That way, they couldn't swallow anything big, and had to live on the lockwashers and little stuff I fed 'em. I even sent through a Minox camera on one of the collars. Most of the time I didn't get very good pictures, same trouble as before, only the other way around. I did get some wild pictures, though, and this was the beginning of the end of an otherwise sweet setup. I began to get frightened. Remember the Russian transistors?"

Several of us nodded. Frankie had had quite a deal on some "surplus" Soviet computer boards and components.

"Well, that wasn't the half of it. Some of the pictures I got back just had to be secret government stuff, and some of it was just plain ridiculous. It didn't even look like it was made by *humans* if you follow me. Finally Athelstan, he was the one I caught first, you know, brought back this. And right then, ladies and gents, was when I got out of the trained glitch business, and went on a nice, long vacation. If you study it, you'll see why."

With that, he tossed the gadget he'd been holding onto the table, chugged the last of his beer and made for the door. The two guys in the coats got up and followed him out. I picked up the thing and looked at it. It was a kind of key, like those fancy ones that they use in the pick-proof locks on vending machines, only a lot more complicated. It had a nylon cord, like a neck loop, and was covered with serial numbers. It gave the impression that if you asked NASA, or IBM, or somebody to come up with an absolutely foolproof lock and key, cost no object, that this would be it. Oh yes, there was a name in front of one of the numbers: "Sandia Corp."

Right about then I noticed a weird, gargling sound, as if somebody down the bar was trying to strangle a Springer Spaniel and not quite succeeding. It was coming from that SAC colonel. He was turning purple in the face and looked like he was starting on a real conniption fidget. He gasped and motioned to me for the key. I flipped it toward him, but it sort of bounced on the table between us, and just kinda, well, winked out!

He looked kind of befuddled for a second, then got up, sort of shaky-like, and ran over to the phone booth in the other corner. It didn't do him much good, of course, because there's no phone in the Antlers phone booth, just an obscene parrot. Not only that, but the parrot is stuffed, as is cousin Suomi on the third stool down from the snake.

The colonel came to his wits, finally, and ran outside to his car phone. In a few minutes, the place was full of Air Police, the FBI, the CIA and the Mounties, as if they had all come down a rope. They gave us all a hard time, keeping us in the place for an hour after closing for questioning, but they never found the key. They really went over the building, too, with metal detectors, and magnetometers. They looked behind every brick and under every floorboard, but to no avail. I think they're still keeping a pretty close watch on all of us regular customers. My telephone sounds like the click room at a relay factory when I pick up the receiver, and my third grade teacher has been interviewed by six different agencies, and offered two bribes.

We never saw anything more of Frankie or the coatmen, but once in a while, when I'm finishing a beer just before last call at the Antlers, I catch a flicker of motion out of the corner of my eye. I like to think that Athelstan and his friends have found a new home. ■

In a few minutes, the place was full of Air Police, the FBI, the CIA and the Mounties, as if they had all come down a rope . . .

Switch It Off First

John H. Smith VK3IQ
83 Bindi Street
Glenroy 3046
Australia

One of Murphy's Laws must be "He who fiddles with radio is going to get electric shocks." I can't tell how many shocks I have had, and almost every active amateur must have had at least one bad shock sometime. Despite the fact that most amateurs have high voltage power supplies, the greatest number of electric shocks come from the ac power mains. I know that most of mine have been ac, and when I asked my friends about their shocks, they agreed with me. The start of this train of thought about electric shock was the 264 volt wallop that I collected from my son's 24 volt electric train set, but more of that later.

One of the greatest dangers of electric shock is its unexpectedness. One minute you are quietly working on the rig and then "Wham," you get a terrific jolt down the arms and chest, and if you are lucky, you yell like mad and curse a bit. "Damn thing bit me," you say, amongst other things. Of course, if you are unlucky, you don't say anything, anymore, and QST has another entry for its "Silent Keys" column.

Most electric shocks come through sheer carelessness. Ac switches placed at the bottom of a chassis are a good way to collect a jolt through the fingers. If you must place switches there, protect yourself from the terminals by wrapping the switch in a small plastic bag or covering the terminals with electrical insulating tape. Transformer terminals should also be covered with a strip of tape. If you must work on equipment that is live to a hundred volts or more, wear rubber gloves. I have saved myself many a shock by this simple method.

Over the years I have had several severe shocks, mostly through my own carelessness. The most severe shock I ever had was due to neglecting the first rule of safety: "Switch it off first." I had been appointed Radio Operator on a one time U.S. Victory ship, the ex "Norway Victory." She had an RCA 4U Radio Console, where the main transmit-

ter B+ of 1500 volts was supplied by a motor generator. The B+ was fed to the transmitter through a long fuse, mounted by the generator starter panel under the console desk. The fault was quite simple, no B+. The fuse, a long brown bakelised paper tube with brass end caps, was probably blown, so without turning the motor off, I grabbed it. It grabbed me too, all 1500 volts of it, and I got an almighty shock which caused me to leap back, cracking my head on the underside of the desk as I shot past. When I had recovered and turned the motor off, I found that some previous genius had also had fuse trouble, but no spare fuses. He had solved his trouble by repairing the fuse; unfortunately for me he had soldered the fuse wire from brass cap to brass cap OUTSIDE the tube. The fuse was indeed blown, but I had made contact with the part of the fuse wire that was still connected to the B+. Naturally, I cursed the fool who had done this, but in truth I was the fool for trying to change fuses in a 1500 volt line with the power on.

Of late, after eleven years ashore, I have become more safety conscious. I have had an amateur station for ten years, but have not had many shocks from it. The first shock I received when pulling the transmitter panel and chassis from its case. The ac switch is at the bottom corner of the front panel, and to ease the chassis from the cabinet I slid my fingers under the panel. Yeeowww! I have now taped the switch terminals, but for greater safety, all the ac power cords are only long enough to mate with their respective power sockets when each piece of equipment is in its case. To remove any unit in the station, it must first be unplugged. If I need to work on a unit out of its case, it must be deliberately patched with a power extension cord. Another safety feature is that all equipment is encased, and the cases are connected together and to ground. In addition, the station ground system is entirely separate from the waterpipe ground of the house electricity supply. This completely separate ground is a great help in avoiding TVI caused by rectification in electricity supply grounds, which may be fine for ac but are ineffective at rf. In addition, the ac line to the rig is only grounded to the station ground.

As an aid to electrical

safety, our local supply authority requires that all power sockets be of the three pin type, with the third pin grounded. All appliances with a metal case must be connected by 3 core flex and three pin plug. Thus, any appliance that develops a short to case will blow the house fuses and protect the user against shock. Every appliance in my house has been checked for safety and found to be in order. All cords were tidy and properly connected, switches were in the active line where only a single pole switch was used, and I was rather proud of my nice safe house. Pride comes before a fall they say.

A couple of years ago, my son was given an electric train set. It was secondhand, but apparently in good order. It uses the all ac German "Marklin" system, using a third rail of studs between the tracks to provide 16 volts ac for the locomotives, plus a 24 volt ac pulse for operating the locomotive reversing switches. I checked that the transformer case was grounded, and that the 16 and 24 volt supplies were the correct value. What I did not check was that the rails were grounded; I merely checked the voltages from center studs to track. The system worked well and it was regularly used indoors. One day recently my son decided that he wanted to use the train set outside in the garden. The track board was placed on the grass, the transformer connected to the track, and the 240 volt mains connected to the transformer, with an extension cord. As I put the locomotive on the track I received an almighty belt that knocked me off balance. I yelled "Turn it off!" and then sat down to recover. I had no doubt that I had received a full mains shock, but how? It was a safe low voltage train and I had checked it. As I thought about it, I realised that I had been between track and ground as I put the loco on the lines, so I put a voltmeter between track and ground and switched on. The reason for the shock was clear — 264 volts! Again, how come?

After disconnecting everything — boy, was I careful now — I examined the transformer. What I found in the box was not a low voltage transformer at all, but a very old radio transformer which some genius had worked out as a cheap replacement for the original. His wiring certainly provided the voltages required, but by

autotransformer action he had left the track live at 264 volts to ground. By feeding 240 volts into a 210 volt tapping he had increased the 5 volts plus the 2 x 2.5 volt winding outputs to 16 volts, but what a death trap!

Before you have your next QSO, have a look at your house. Is everything electrically safe? If not, fix it fast or call an electrician. Have a look at the rig. Are the cases grounded? Are the cases on a good separate ground? Are there exposed B+ or ac terminals? Can you get across transformer or switch terminals while working on the rig? Think, for a minute, of your family, of your insurance company. ■

Improving the FT-101

Do you feel that your earlier FT-101 could use "just a bit more" receiving selectivity on single sideband? How would you like to accomplish this at a reasonable cost, simply, quickly, and *without* butchering up your pride and joy?

I already had the FT-101 "160 meter model," so I could not see paying the couple of hundred dollars difference to trade for the "B" model. A closer scrutiny of the Yaesu price sheet revealed a "XF-32A, 8-pole, SSB Filter for FT-101B, for $49.00." Now what was that all about? The FT-101 *B* already *has* an 8-pole filter! Yaesu Musen in California explained that this filter is used to upgrade the earlier models of FT-101. They also told me that this filter will not affect the operation of the earlier models, except to give them more receive selectivity and to narrow the speech bandpass when transmitting. They also told me that this filter will *not* change the interstage drive requirements, *nor will there be any retuning of any kind,* within the rig. Well, this is right up my alley!

Splurging and Installing

I sent Yaesu Musen USA, Inc., the money and

received the filter in one week.

This filter is installed in place of the present 6-pole unit, model XF-30A, designated as XF-1 on the schematic. This is on the I.F. UNIT, plugin (held in by screws) circuit board, which is easily accessible, from the top of the rig. The A.F. UNIT has to be removed first, which is also a plugin circuit board, before you can remove the I.F. UNIT board.

Using a little care and working slowly, the time required from unplugging the boards, switching the filters, to replacing the boards can take less than an hour. Don't forget to remove the old filter's two hold-down nuts and lock-washers, prior to unsoldering! The greatest time is spent at unsoldering, and at the same time, working the old filter out of the I.F. UNIT board. Take your time here. When the old filter is finally removed, carefully clean out the filter's printed circuit connections' holes and your new filter will literally drop right in.

Holding the new filter in place, replace the hold-down nuts and lock-washers. Solder the connections. Plug the I.F. UNIT and A.F. UNIT boards back into the transceiver, fasten the holding-screws, and fire up!

Results

The first thing I noticed was the sharper tuning on SSB. With the old filter, the signals used to "plop right in" as I tuned across the phone portions of the bands. Now, I have to tune a bit slower. One quickly gets used to this. The new filter reduces and practically eliminates "monkey chatter" and "growls" caused by adjacent signals. The eight-pole filter certainly performs better than my outboard audio filters! ■

Reference

1. Yaesu Musen USA, Inc., 7625 E. Rosecrans Avenue, Unit #29 Paramount, California 90723. "XF-32A, 8-pole, SSB Filter for FT-101B." $49.00 plus $1.00 postage.

Put Your SB-10 on 160m

by
Arthur Eckman WA2ECI
11 Fort George Hill
New York City NY 10040

Having two Heathkit SB-10 sideband adaptors for use with my Apache, I converted one to 160 meters for use barefoot or with my Apache final. There is at the input of the SB-10 a pair of 45 degree phase shift networks, providing a total of 90 degrees rf phase shift. Each consists of a series of exact value capacitors (one for each band), and a ½ percent 50 Ohm resistor.

I used the 80 meter position of the bandswitch for the 160 meter conversion, as that provides the most inductance in each tank circuit. The value of the 160 meter phase shift capacitors was determined in the following manner: First a graph was made of the provided phase shift capacitor's values versus frequency. Then I extrapolated the graph to get an approximate value for the capacitor for 1.8 MHz. It turned out to be 1200 pF. I then purchased a pair of 383 pF capacitors which when added to the existing 817 pF 80 meter capacitors provided 1200 pF each.

The various tank circuits were padded to 160 meters as follows: 120 pF was added across each section of the dual 50 pF balanced modulator tank variable, 36 pF was placed across the 80 meter coil in the 6CL6 tank, and 150 pF was placed in parallel with the 6BQ5 tank variable.

With the balanced modulators unbalanced, about 2.5W of 160 meter input yielded over 5W of output. Sideband suppression was about 30 dB at a frequency of 1.880 MHz, plus or minus 5 kHz.

Desiring to use the SB-10 at frequencies below 1.850 MHz, I determined a more appropriate value for the 1200 pF phase shift capacitors. Using the slope of the graph at 1.8 MHz, I calculated I would require 1240 pF capacitors. With these capacitors in the circuit maximum suppression was at 1.825 MHz.

Normal operation can be restored on other bands simply by removing all padding capacitors.

I drive my 160 meter SB-10 with a hastily built novice special from the *Handbook*. To use the Apache pi network on 160 meters, place the bandswitch in the 80 meter position, and add the capacitors shown in Fig. 1. Put 730 pF at 2000 volts in parallel with the plate tuning variable capacitor and 3150 pF in parallel with the loading capacitor. The capacitors used for the phase shift network can be obtained for $2 apiece from: Leeds Radio Co., 57 Warren Street, New York NY 10007. ■

Long Beach CA 90802

WH6DBF - K1OXK - W6LZJ

Who can say where it began or how it got started? One just knows that suddenly there was this desire to communicate by amateur radio. I suppose watching my father building that Harkness two tube reflex and later as he assembled the parts to our first Atwater Kent on the "breadboard," the "bug," as it was once called, bit me! I had my turn at winding coils and putting together crystal sets for the boys down the street. (Early 1920s.)

Certainly, I shall never forget the day I completed the "Junk Box Short Wave Receiver" as per the instructions in Radio News Magazine. It had plug-in coils wound on the base of old radio tubes; some of the coils being somewhat longer were wound on toilet paper cores and then glued to the tube bases. Carefully, I hooked up the batteries and turned on the filament switch. It worked! I shall always remember that British accent as the announcer said: "This is GSD, Chelmsford, England....the pride of the British Empire." (Late 1920s.)

My first transmitter was a 20 A operating just in the high end of the broadcast band. I tucked the telephone type carbon mike inside the horn of the Edison phonograph, and cautioning one of my brothers to keep the spring wound and the record playing, I hopped on my bike and off I went to my grandmother's house, about three miles away. Lo and behold I found it on her Atwater Kent Radio. The Dance of the Hours was not loud but to my ears it sounded just great. Wonder if they had an FCC in those days and if they did would they have taken me in? If not, would what I have told you here be a case for a retroactive hustler?

From the day I was able to hear Hersh Calvert and the hams of Pasadena on my junkbox radio, I knew that some day I would be a ham too. A friend of mine at John Marshall Jr. High School by the name of Harry Grace was a ham radio operator and showed me his station. However, he only operated on CW so that as I did not know the code well enough to copy, I was not greatly impressed with Harry's station. Later I was to be permitted to speak into the mike at Dow's Radio Store on Colorado Street in Pasadena. Dow had his big rig just inside the front

window in those days. I joined his ham radio class but I just didn't learn the code fast enough.

The day World War II ended I stopped at a drive-in in San Clemente to get a cup of coffee. There I met a ham whose call I've since forgotten but I caught the bug again from him. Somehow I acquired a beautiful Scott or McMurdo Silver Radio in a chrome or nickel plated cabinet. How that cabinet shone when polished; you could see to run the comb through the locks (in those days I had hair). It was there that I learned to light up a defective flourescent lamp with the rf generated by a low power oscillator.

One of the lads in our Rotary Club High School Youth Group by the name of Ted Casad showed an interest in studying for his ham ticket. So thinking that I too would get mine, I worked with him through the hours of sending and receiving code and studying the theory. When we went to the FCC offices in San Diego, Ted passed the code test, I flunked. Ted became W6AMP. How appropriate after all that study....to get A M P.

When we moved to Honolulu, Hawaii and St. Peter's Parish I purchased an Hallicrafters SX-28 and listened to the hams whose ranks I still longed to join. I became acquainted with KH6BFF "Baker, Fox, Fox." Is there a ham who hasn't worked Smitty? He has handled traffic for and in and out of the Islands before, during and after the war. Whenever Smitty signed his call to end a QSO, there'd be another call waiting, usually requesting a phone patch into the Islands. Smitty is as hospitable in person as he is on the air. You would never know that he has a sight handicap unless you were to visit him.

One day while visiting the Mental Hospital on the windward side of the Island of Oahu, I noticed a fine beam antenna riding high on a tower. I rang the doorbell wondering what I might say as an excuse for stopping. The greeting I received quickly dispelled my misgivings and soon I was looking at a ham radio station shared by Bernie and Kayla Bloom (who later became editor of 73). I learned that since Bernie was a psychiatrist on duty at the hospital most of the day, Kayla was able to take advantage of the band openings which were very good in those days.... 1958 - 1959! Kayla had a contest going with Bernie and the results were depicted on a huge map displayed on one wall of the shack. There were two colors about evenly divided around the world as the

pins represented their DX contacts. I was invited by Kayla to visit the HARC, The Honolulu Amateur Radio Club, which met at one of the U.S. Army Forts out at the end of one of the buslines from town. It was dark there at night and not easy to reach after hours. Later I was to be the instrument by which the board of directors of the club were to be persuaded to move the club meeting place to the parish house of St. Peter's Church.

Fate had finally smiled upon me! One of the clergy stationed out at Wiamanalo Beach, Lamar Speiers, was a ham radio operator. I met Lamar and through his assistance and guidance learned the code, the theory and studied once again for that so elusive ham ticket. Yes, I finally passed the examination! While waiting for the call to arrive, I met a ham who was going to get married and whose fiancee wanted him to give up ham radio, first! He had two Heath Kit rigs for sale. One the DX-35, the other the Apache. I bought both in my enthusiasm. Neither was in working condition so that when my ticket arrived one really gorgeous day in December of 1958, I got that DX-35 out on the floor and compared it with the wiring diagram (yes, fortunately it came with the rig). Ah, there it was, one of the wafers of the band switch had a broken or missing contact. I installed a SPST toggle switch in such a manner that when I reached into the cabinet by sticking a lead pencil (eraser-end-first) through a tiny hole in the rear of the set, I could just throw that switch. It connected an rf bypass condenser to ground...or did it?

By noon of the day my call, WH6DBF, arrived I was on the air calling "CQ, CQ, CQ, de WH6DBF, WH6DBF, WH6DBF k." I was answered immediately by a ham in Pearl City out by Pearl Harbor. 40 meters was working!

I ordered a custom 3 element monoband for 15 meters. It was made for me by an antenna manufacturer in Honolulu. Finally, one Saturday afternoon, one of my congregation, David Chang (also a ham radio operator, though not active at the time), Smitty KH6BFF and other ham radio operators in town converged on St. Peter's Church and helped me install the beam atop a rotor and mat on the roof of the rectory.

I am afraid I spent more hours that first year than I should have in CW QSOs

around the world. My goal: to get that General ticket before the Novice ticket expired.

In August, 1959, I was invited by KH6CUP, the president of Precision Electronics (my favorite ham store in Honolulu) to man a Novice booth at the 1959 ARRL Convention held in the Kaiser Hotel Building. I won only one contest in my life and that was during the convention; I was given a set of crystal earphones as a prize for having the most verified DX QSLs in the Novice class. I still have those lightweight "cans."

The definition for privilege in the American Heritage Dictionary here at my desk is: "...benefit enjoyed by an individual or class." I like that! How better can one describe the thrill that goes with passing on to others the know-how of ham radio? It is definitely my privilege as a radio amateur to give to men and women who are interested the opportunity to become licensed amateurs. Just as soon as I was oriented as a Novice, the station operating, the antenna trimmed and set, my QSL cards printed and the ink scarcely dry...I was organizing a class for Novices and Generals. David Chang of my congregation who did so much to assist me in Honolulu took the class for Generals; I took the Novices.

If you ever get the chance to visit the HARC in Honolulu, do so! I have never seen a more dedicated group of men and women, boys and girls as constituted the Honolulu Radio Club. Hams came from the other islands to make the meetings. Young people sat up front busy taking notes while the speaker for the evening told us of the mysteries of skin effect and the ins and outs of swr. After the serious part of the evening was over, there was a big drawing for the many door prizes, a chance to swap one's "goodies" for someone else's. The refreshments were often homemade and donated by one of the YLs, or are they Female Radio Persons these days? I loved them all.

Suddenly, it was all over! We packed all our earthly goods in a sea van including the ham radio gear. I made a presentation of the 15 meter beam to a friendly young Novice in Honolulu. We sold our Wurlitzer 2-manual spinet to another ham friend, KH6OES, and embarked for Boston, Mass.

The night of December 1959 when my Novice ticket expired, I sat up until midnight wishing

that I had a rig for a last CW 73. I had tried all over Boston to find one ham who had a Novice rig he might let me borrow for that last night. It wasn't to be. Perhaps, however, it became a spur to go on for the General. I learned that one could study for a ham ticket at MIT in Cambridge, Massachusetts. It was there that I met Bill and Marie Welch; it was there that I took the Technician test and then dropped out because of the press of church activities in Boston's South End. I was stationed then at St. Stephen's innercity mission.

When K1OXK came through the mail, I bought a Gonset Communicator 3. I met hams all over the state. I joined the Six Meter Mobileers and the 51.30 Club which met on the air every night to chat and once a week for business at 51.30 MHz (only it was MCs in those days). The social affairs of the fifty-one-thirty club were great. I still miss the contacts I made on six meters. They were gentlemen and ladies all.

It was through a contact on six meters that I met Joel Nichols K1MUE. I was later to be asked to join that confirmed bachelor in Holy Wedlock with the widow of another ham friend of mine. Joel and Gladys were married in the home of K1KQJ, Karl Miles, the friend of every six meter operator within working distance of his hilltop home in Wilton, New Hampshire.

Our first Vicarage in South End Boston was two doors from the New Haven railroad line. If I happened to be on the air when the train came by, I took a bit of ribbing from my friends in the QSO. "Why don't you get off the track and let that train go by?" "Is your shack built over the tracks?" In the second Vicarage we were ensconced in a former hotel for women provided the church by the YWCA. The shack was in a corner room on the fourth floor. Ed, from "the garden spot at Scituate on the south shore" helped me get the six element Hy Gain beam installed. You would have appreciated the stir we caused when Ed decided we didn't have to disassemble the beam when it came down from the roof of the small four story tenement by the New Haven tracks. Tied to a rope and dangled over the edge of the roof, the antenna was lowered slowly to the front walk. Ed took one end and I the other and with 20' of boom and all the elements intact we began walking the ¾

of a mile that led to the new QTH. Traffic, both mobile and pedestrian stopped to gander at this contraption with many arms and four legs maneuvering down the walk. "What is it?"

It seemed appropriate at the time to respond with: "It's a TV antenna for getting stations from out of state!" I'm sure many thought that that was just what it was.

One hears a great deal of conversation about hams who stay on six and two meters, content to operate with Technician class licenses. Certainly there is much to be said for doing so; I enjoyed those years beyond anything I can now tell you. Friendly QSOs every evening I was free to operate. Volunteers when needed to help install another new beam or to repair an old one were available as close as the microphone on my rig. DX was just as thrilling on six meter skip and when working the aurora as it had even been on the low bands.

You might wonder then why it was that I even bothered to go for the General ticket. I remembered Bill Welsh's admonition: "Don't get stuck on six meters...go for your General!"

I had only tried once to pass that insurmountable hurdle and that had been in Honolulu. I was at that time more concerned about passing the theory than I was about the CW test. After all, I was in CW QSOs at some time of every day — working actually around the world. For every DX contact I would answer requests for contacts from California and every other state in the Union. You know what happened, of course! I flunked the code test! All the numerals sounded like Js and Zs!

In 1964 we moved to Andover and took a parish in Lawrence, Massachusetts. Here I had the use of a rectory, a ranch style house with a full basement. One corner of the basement had been partitioned off as a den. It was here that I set up the six and two meter rigs. By this time we had disposed of the Gonset 3, purchased and used for some time a Gonset G-50, and now owned a Clegg Zeus and Interceptor for six and two meters. Shortly after moving to Andover I arranged to spend a few hours each day copying the code tape on a government surplus machine. Finally, with new confidence in my code speed and accuracy I thought I was ready to go before the FCC examiner.

I made arrangements to take the General examination at the New England Hamfest in the New Ocean House Hotel in Swampscott. My friends cautioned me that it would be harder there due to the confusion and noise. I was the last one to be allowed to "send" the code after passing the receiving test. Thus, as I recall, among the last to enter the other room where the test for the theory was being administered. I finished so soon that I thought I must have missed something, and took another look before turning in my test. You know what a thrill it was...when I came back and read my name up near the top of the list of those who had passed!

Now, it was a whole new ball game; only a ham who has been on six meters or two with no hope of working the low bands can know how difficult it is to get into a good CW contact on a regular basis. I had missed those CW QSOs in the Novice portion of 15 meters...a window wide open to all the world with a vast view of all the continents and many ships and islands in the seven seas.

One half of my shack now became a low band station with "my poor man's Collins: the SX 117 and the HT 44, matching units by Hallicrafters." The rectory yard on the west side now became a small antenna farm. Inverted Vees for 80 and 40 meters, a 2 element Hy Gain beam for 10, 15 and 20 meters, and stacked six and two meter beams. I've never had it so good since!

Here in Long Beach, California, we live in an apartment, and while our landlord is a former ham, there really isn't much room for a satisfactory antenna installation. I live in hope; if any K or W6 reads this sad tale, and wants to make a fellow ham happy in his "old age," please drop by and let's see if we can't put up an antenna that will at least work Honolulu. I hate to think that I will have to move back to New England to get on the air again. Still it wouldn't be such a bad idea; I'd like to see and talk to my many friends back there once again. One more reason for having an antenna that works at my present QTH!

By the very nature of my profession I meet many people of all ages and races. But if I had to choose a hobby to take the place of ham radio, I'd be lost. Nothing I can think of takes the place of amateur

radio; I sincerely hope that in the years to come every generation of young people will be encouraged to become amateur radio operators and to use their talents to communicate across the seas and perhaps some day throughout our solar system or beyond.

Once a year in the early fall when the resort rates fall to levels a ham could afford to take advantage of, a group of six and two meter hams used to get together for a weekend of food, fun and fellowship. A fine supper around a large table, a speaker or just table conversation during the evening and then the next morning after early coffee together we'd go somewhere for breakfast. Our genial host for those Friday night affairs was Jim K1VPE of Moody Beach, Maine. His XYL Betty would have everything all set and ready for us when we arrived. Jim would open up his private den (like a small night club with tables and spectacular paper on the wall...and a dandy bar) to our small group. One of the rare treats that were a bonus of those weekend retreats was to awaken early and walking upon the beach see a Canadian goose land on the sand nearby. What a proud bird they are. No prouder bird than that ham who for the first time opens the envelope and removes his FCC ticket to the airways. No prouder member of the human species than that ham who having built his first rig, turns it on and it works! No happier ham in all the world than the operator who having called his first CQ... hears his call coming back from another station... down the street or from across the world it's all the same!

I know I could write a book about the fun and people I've met in ham radio. There just isn't room in *73 Magazine* for it; but I am pleased that I had this opportunity to share some of it with you. If any of those fellows I've had the pleasure of helping to get their tickets should read this, I certainly would like to hear from them. Where they are living, what sort of a rig they're running and what's new with them since we last talked.

If you are not a ham and are looking for a way to make lasting friendships and a hobby that's enduing, write me or visit with your nearest ham and go with him to a ham radio club. You'll be glad you did! ■

Maintenance Musts

Paul Schuett WA6CPP
14472 Davis Rd
Lodi CA 95240

Anyone who holds an amateur license of Technician or higher, or a first or second class radiotelephone license, should be capable of performing repairs and maintenance to his own, or almost any, equipment. The FCC, by issuing the license, has certified the holder as being competent. The licensee should be able to prove it.

In fifteen years of commercial broadcast experience, I have only needed to ask outside help two or three times. Of course, in a number of situations, there was another engineer working with me on a project, and two heads are better than one; but more often than not the broadcast engineer, as well as the amateur, is on his own. Using common sense and remembering his theory will solve almost any problem that comes up.

Most troubles that happen can be listed in six categories. Arranged from the simple to the complex:

1. Tube troubles.
2. Power supply troubles.
   a. Plug it in
   b. Blown fuse
3. Misadjusted circuits or controls.
4. Dirty contacts or controls.
5. Loose or broken connections or wires.
6. Deteriorated components.

Tube troubles happen most often and are relatively easy to correct. First, look to see if all the filaments are on. Simple as this sounds, there are many people who don't do it. Find out which circuit doesn't work and substitute tubes in it; or better yet, check them all in the tube tester. One of the first things I bought when I established my amateur station was a reputable tube tester. The Eico 667 comes in kit form, is priced right, gives a valid test, and has instructions on how to set up for new tube types. An adaptor is available for testing older tubes in case you run across an 83 or something; a magnoval and ten-pin adaptor are also available.

This unit comes with a pilot light checker in the novar socket. I replaced the socket (30 cents or so) because many novars have the air seal at the bottom, and this prevented the tube from being inserted in the socket. (Pilot lights can be checked from the grid cap to ground.)

It is a wise practice to throw away weak or burned-out tubes. It is also wise practice to keep a spare or two around just in case you lose a tube at 5:10 pm Friday and your friendly parts house won't be open until 9:00 am Monday. I keep at least one spare for every tube type, or if more than six are in use, at least two spares. For finals, I keep two so that they will be both of the same approximate age in case of being changed. Tubes don't cost so much that the smaller receiving-types can't be kept on hand. The popular 6146 is relatively inexpensive, although a 4-1000A is a different story.

From experience, most power supply troubles are caused by something not plugged in, like the ac cord, or a more exotic example, the rectifier plate cap is not connected. Look for dirt on the plate cap. It goes without saying to look at the fuse early in the game; I learned this one the hard way once.

Most amateurs should be able to locate misadjusted circuits or controls. Tanks may not be at resonance. Neutralization may not be correct. Bias or drive may not be proper. A good VTVM and VOM are worth their weight in Extra Class licenses at this point. I have one of each. Eico and Heath make excellent kits, or you can go full blast and get a Hickok or Triplett. After building my kit, I sent it to the repair station for calibration since I also use it in broadcast work. Not having a voltage standard available, and not relying on the power company's 105-130 volt source, the $5 was well spent. With these units standardized, you can calibrate other equipment against them.

At one broadcast station, the FCC required the power to be reduced at local sunset. This was easily done by operating a switch marked "1000-250" on the transmitter. One operator somehow got confused and operated the control marked "Buffer Tuning." This took out two 807s and a fuse.

Dirty contacts are responsible for many things misfunctioning but can be difficult to find. A regular program of squirting contact cleaner (don't use carbon tet) into all rotary and lever switches and into all relay contacts will make troubleshooting ex-

peditions as rare as a contact with Tibet. A contact burnishing tool is quite useful, but please don't use a nail file. One way I have used to locate the more exotic problems of this nature is to put an audio tone (I like 400 Hz) on the line in question and trace the signal with a scope. With a scope you can tell the frequency of the signal, whether any attenuation has acted on it, or amplification; you can see extreme distortion, and if there is no signal where there should be, you know the circuit is open.

One broadcast station had several clip leads connecting various parts of the audio console. When rewiring the control room, I removed the leads and found one of the output channels didn't work. Using the signal generator-and-scope method, working back from the output, I found the signal was blocked by DIRTY SWITCH CONTACTS. Somebody had used these leads to bypass the switch instead of squirting the cleaner into the contacts.

Loose or broken connections can be braincrackers, especially the intermittent type. After disconnecting the ac and grounding all filter capacitors and high voltage points, pull and shake every wire you can find. Using an ohmmeter can show high resistance connections that shouldn't exist. After using the equipment, and removing all voltages, look for warm places (current thru high resistance means heat). Of course, if smoke comes out, you can find it right away. Check all connections against the diagram; check all socket voltages and resistances. In one commercial transmitter I found a missing ground wire on a meter switch rendering two positions inoperative. My own scope stopped working once; a filament lead rubbed where it went around a corner, shorting to ground, hence no filament voltage. Find out which sections work OK and which don't. Modern plug-in transistorized modular construction is wonderful. Pull out the defective board and plug in one that works, then do the maintenance at your leisure.

The operators at a broadcast station once told me the transmitter would turn itself off and they'd have trouble getting it back on. I figured they were running it wrong since I never had the trouble. One night, during routine maintenance, I couldn't get it to go on either. After three hours of pulling, pushing, kicking, tapping, etc., I saw an arc in the output section. The trouble was in a variable inductor —

the contact wheel was not making good contact and opening, and the overload relay turned the transmitter off. A very simple situation that took a long time, and a lot of luck, to find.

After any equipment gets old enough, components will deteriorate. Capacitors and resistors will change values, insulation will crack and peel, phenolic switches and circuit boards become brittle and crack, screws and bolts become loose and fall out, and all sorts of other mysterious things can happen. Often it is easier and cheaper to replace the whole unit than to repair it piecemeal. These printed circuit boards, if cracked, will in effect break the printed connections. Even a microscopic crack will open a lead. A bead of solder down the conductor will repair the break. For transformers and chokes, replacement will be necessary if the voltages deviate excessively from original values. Likewise, resistors and capacitors will have to be replaced if they no longer do the proper job. The enemy of components is primarily heat and dirt. If you keep both at a minimum, you will have minimum troubles in later years.

Place everything so that proper ventilation is assured — this keeps the heat down. Generally, commercially-made equipment and kits are well designed to remove heat properly. Leave lots of room for circulation of air.

Make dust covers for your equipment. At WA6CPP, the XYL is quite accomplished on the sewing machine, and made some plastic dust covers that exactly fit the various components, including the power supply-speaker units. When not in use, these are protected from the ever-present dust filtering in. At one commercial station, nobody dusted or vacuumed for three years before I got there, and the dust had turned to mud. Nobody will get mad if you use the vacuum cleaner to blow the dust out of things once a month or so.

Perhaps some of these suggestions reflect my work in commercial broadcast, but I don't think any of them are impractical for the average amateur. After all, when we have spent many hundreds of dollars and countless hours on our stations, we should take care of them properly. When, from time to time, something goes wrong, the license holder should be able to fix it. In some cases, you may have to use the land line to call your friend across town to give an assist, but it would be

CORRECTION

In the article, "Updating the Heathkit IB-1101," in the Nov/Dec issue, there are a couple of mistakes.

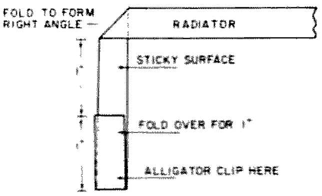
In Fig. 2, front wafer, V2 pin 14 and V3 pin 14 are reversed. V3 should be the top lead shown.

The printed circuit board in Fig. 3 has a mistake. The ground connection of the 7490 should be pin 10, not pin 9 as shown. Pin 9 is not utilized by this circuit.

OUR APOLOGIES to WA2APJ and WB2AQM, for transposing their photos on page 11 of the January issue.

embarrassing to me to send something to the manufacturer or repair station to have a broken wire fixed.

One evening I was trying to get an auxiliary transmitter to work. Having just started to work at the station, I was getting everything in A-1 condition, but it was impossible to get high voltage to that auxiliary. The tubes lighted up OK, and the meter showed crystal current and buffer grid drive, but that was ALL. I was about ready to check for bias voltage when I thought I'd check the primary supply. Well, this rig had two primary supplies — 110 volt single phase and 220 volt three phase. Somebody pulled the breaker on the 220. After that, it worked great. Let's see, that's reason 2, Power Supply Troubles, Plug It In. ■



Alarm Foil Antennas

Larry Kahaner WB2NEL
4259 Bedford Ave.
Brooklyn NY 11229

While in my neighbor's house one day explaining how I can phone patch her brother in Germany, I spied a newly installed alarm system. It was the usual type in which thin foil is taped around the window to form a closed circuit. When the window is broken, the foil circuit opens and the alarm sounds. The foil looked so pleasant and neat on her huge picture window. Since I am always looking for new types of radiators (and what ham isn't?), I wondered about alarm foil. Indoor antennas are not new to me. I had some indoor dipoles in my old apartment but they always looked so ugly and had to be removed when guests came. Perhaps foil was the cosmetic answer.

Window foil is not as easy to obtain as one might expect. It seems that the alarm installers want to keep business to themselves and frown on home brewing interlopers. I called a few places and they refused to sell it to me. This is odd because both Lafayette and Radio Shack have it in their catalogs. I finally got a roll from the man who installed my neighbor's alarm. A 200 foot roll cost about three dollars. The tape I bought has a paper backing which is peeled away exposing a sticky foil. I made several tests and found that the tape could be applied to a painted wall and later removed without leaving

a mess. I advise against placing it on wallpaper.

My house has a crown molding on the top perimeter of the room and I applied the tape in dipole fashion starting from the center. At the feedpoint I folded the tape on itself for about one inch. The tape exhibits great strength to pulling apart but will tear easily if twisted. Fold the tape at right angles to prevent the coax weight from tearing it. If you make a mistake or tear the tape, another piece overlapped will make a tight contact despite the adhesive. Check with an ohmmeter if you feel insecure. I thought of different methods of feeding and decided that the simplest was also the best. I used alligator clips from my coax. This would allow me to remove the coax without taking down the antenna. Coax climbing a white wall leaves much to be desired.

With everything in place, I loaded up the rig. My match box was waiting in the wings. My transceiver loaded up easily with an swr of 1.7 to 1. Since my calculations were for the center of 20 meters, I peeled and cut a little off each end until it was perfectly matched for the center of the phone portion. I tuned and heard a very strong CQ from the Midwest. I answered pessimistically and he responded with a 57 report. Other reports from that area were also encouraging.

I added some tape to the ends and pruned it for the low end of the CW segment. That afternoon I worked 2 Gs, 1 I and 1 DK. All were better than 459 reports. Input power was 180 Watts. It is not necessary to add and subtract tape for each segment of the band. It is as broadband as any other dipole but I felt that any extra push was helpful.

The configurations of foil antennas are limitless. If your apartment is the right size you might try putting a reflector or director on an opposing wall in another room. With a matching network you should be able to work the low bands with a shortened antenna. It would also make a great "long wire" for the SWL who is apartment bound. Even though the adage "the higher the better" still applies, if you live on the 29th floor of a 30 story apartment house, the working difference between crown molding and baseboard mounting will be minimal. And, it will be better hidden on the baseboard. Window foil is especially good for sealing rf leaks in home brew chassis. And I have found that a folded dipole of foil hidden on the back of a dresser makes a fantastic antenna for commercial FM reception.

Dipoles can never compete with 4 element quads up 75 feet, and indoor dipoles even less. But for the ham living in the canyons of the big city an indoor foil antenna can be the answer to never getting on at all. ■

Alarm! Alarm! Alarm!

The simple alarm circuit described here may be built for about $5.00, and unlike most systems which merely turn on a light or sound a horn, may be set to intermittently energize a horn, lights or other signaling device, on and off at any speed you desire. This intermittent alarm will be easily recognized by you and not mistaken for just another stuck horn.

Once activated, the system cannot be shut off without disconnecting the primary source of power. In the standby or arm mode, the circuit draws no power until triggered. The unit may be operated on any dc voltage between 6 and 15 volts. The relay

chosen should be compatible with the supply voltage; however, the ON/OFF timing will be independent of this voltage.

Applications of this alarm are varied and limited only by your imagination:

Automotive: hood, trunk, doors.

Motorcycle: mount under the seat — any attempt to move the cycle off its stand will trigger the alarm.

Equipment: mount inside or on the back of the rig — attempts to physically move the equipment will trigger the circuit.

Pool or Sump Pump: Replace the mercury switch with a pair of sensor leads mounted just above the desired water level. Water touching the leads will trigger the alarm.

Touch Switch: Sensor leads or a grid board will activate the circuit when touched by hand.

The circuit is simply an SCR switch activated by a mercury switch or sensor lead. Once triggered the SCR remains ON supplying operating voltage to the 555 timing IC. If the alarm device uses 200 mA or less, the relay is not needed. If the load however, uses more than 200 mA a relay should be incorporated and have a coil rating for the operating voltage used.

Due to the limited number of parts in this project, assembly on a small piece of perf board or plastic may be used. The use of a small relay will allow you to build this alarm on a 1X2 inch square board or if a smaller unit is required, the relay may be outboarded.

All components are available through your local Radio Shack stores. ■

EDITORIAL BY WAYNE GREEN

from page 17

The general rejoicing was cut short when we started to come back to a W9 which had been calling, only to see the Bird wattmeter drop off rapidly to zilch . . . followed by a little curl of smoke from the TPL amplifier. Well, thank heavens we'd made one contact before Murphy took over, zapping the most expensive and hard to replace part of the system.

Oscarites . . . we shall return.

OH PIONEER!

Many of us reflect, as we drive along listening to the idle chatter coming through the repeater, that radio amateurs have been outstanding in their pioneering work . . . and we wonder how we might be able to do something of value. It's a little depressing to think of being up against a professional laboratory or a well-funded government grant project, but the fact is that there are many areas where we have a decided advantage.

An article in the December issue of *Modern Photography* pointed out how much work there is to be done in the field of Kirlian photography . . . a sort of electronic photography discovered by Semyon and Valentina Kirlian in the Soviet Union. There was quite a bit about this in the pocket book *Psychic Discoveries Behind the Iron Curtain.* The pictures are made by using a low current supply, around 10,000 volts, and putting the film and subject between two plates with this voltage on them . . . exposure around two to six seconds. What results appears to be tied in somewhat with the human aura, plus some other impossible-to-explain effects.

A Kirlian photograph of a leaf, part of which had been cut away, still showed the complete leaf! Bright points of light appear on photos of hands and these appear to be concentrated at the same points used by acupuncture!

This is a new field to research, is relatively inexpensive, and would seem ideally suited to many radio amateurs who have the needed combination of electronic and photographic experience.

Another area ripe for the lone individual, and not requiring a lot of lab equipment, is the development of computer programs for the new microprocessors . . . the major weak link in the growth of computers today. The writing of complex computer programs is necessarily the work of an individual, and the time required is of an order that greatly restricts commercial companies from just paying someone to do the job.

While an amateur radio set is ready to use when you plug it in and turn it on, like just about every other electronic device with which we are familiar . . . not so the computer. Your not inexpensive microcomputer will just sit there and not do a dammed thing when you plug it in and turn it on . . . unless you have some programming to get it going. Newer systems such as the 6800 series computers have a ROM included which has the programs on it to get the system up and running, but the 8080-based systems don't . . . as yet.

As of this date, to the best of my knowledge, none of the microprocessors have anything much more than Basic language ready to use. The Altair Extended Basic is being worked on and should be ready before long, but it's taken a lot longer than anyone thought it would to get the bugs out of it. Also, as far as I know, none of the systems are yet ready to use floppy disks, mag tape, or even cassette tape for much more than program entry. All of these things call for programs to be written . . . and that means a lot of time and work. This also means that there is a very wide open opportunity for some people to contribute substantially to the progress of microcomputers.

READER SERVICE

Now look here, good buddies, I don't want to come off as a scold, but the reader service department has been griping something fierce to me that there are several readers who have not been holding up their end of things . . . that they haven't been sending in their reader service requests. Mary, who takes care of that department, has those great big liquid brown eyes and if you could see the tears well up in them when she runs out of labels to send our advertisers you would run, not walk to your mail box and send in for some of her loving care.

Yes, I know you don't want to rip up the magazine, and you don't have to . . . if you don't have a copier handy then just make a note of the advertisers or the numbers of them on a card or shred of paper and send it in to Mary . . . she's a lovely person. Please don't be callous and cruel and forget our Mary.

Look, just because you ask for information doesn't mean you *have* to buy something . . . at least not from every advertiser.

Well, anyway . . . get busy and mark the heck out of that coupon . . . okay? ■

EDITORIAL BY WAYNE GREEN

SUE THE BASTARDS

Though we try to put as good a face on it as we can, the fact is that every now and then we have our little trouble spots within Amateur Radio. Alas. When we run up against someone who is being unreasonable (defined frequently as not agreeing with me), we get mad and try to get someone else to do something. We may try to bring the FCC into our problem . . . or even lawyers . . .

May I remind those who are caught up in a repeater war, fighting a pirate repeater, or trying to keep an organized net going through deliberate interference, that though it is difficult not to lose perspective, that these are the times when you should reference the amateur regulations . . . the part where it says that we are largely self-regulating. You are now in a spot where self-regulating is called for and you haven't figured out how to regulate the SOB who is making life miserable for you.

Further reminder . . . this is the time when you will find out who has the most brains. You are in a fix and you need to be able to outsmart someone . . . the FCC is no answer to anything . . . neither is a lawsuit. If you bring the Candy Company in you could easily end up with a bunch of rules which you and several generations of hams will hate. And if you bring in the lawyers you could end up with laws you won't like. Remember that when cases get tried in court they form legal precedents, and once set, they are very difficult to upset.

What I'm saying is that there are a lot of very good reasons for Amateur Radio to stay self-policing. Any time we can't seem to make it stick by ordinary peer pressure, we ought to call a council of amateurs and see if someone can come up with a good proposal. It may mean a mass visit to an offending amateur to try and reason with him. If that doesn't work, then either sterner measures or else more brainstorms are needed . . . but, please . . . keep the lawyers and FCC out of our problems.

CB GROWTH

All those beautiful stories in the newspapers about CB have had an impact, as is obvious by even more articles appearing in the papers. The FCC reports that while it took sixteen years for the first million CB licenses to be issued, the second million took eight months, the third million three months . . . got the picture?

Now let's suppose that our national organization of Radio Amateurs got busy and set up a PR firm to start getting articles on ham activities in the papers and magazines. The media is the message these days, as all of us know, and newspaper articles obviously make an enormous difference. We wouldn't get millions of hams, but we certainly would see a big upswing in interest . . . clubs would find people clamoring to get into their license study classes and we would start having enough amateurs to get activity on some of our presently vacant bands such as 50 and 220 MHz. Let's put 28 MHz in there too.

What would such a PR effort cost these days? Maybe $100,000 a year . . . about 35¢ per amateur . . . about 5% of said national organization's annual budget . . . and, if they really have the 100,000 members they claim, that would be one buck per, cheap enough. If I mention it to them they'll just get mad, so it's up to you to bring it up. Don't mention me.

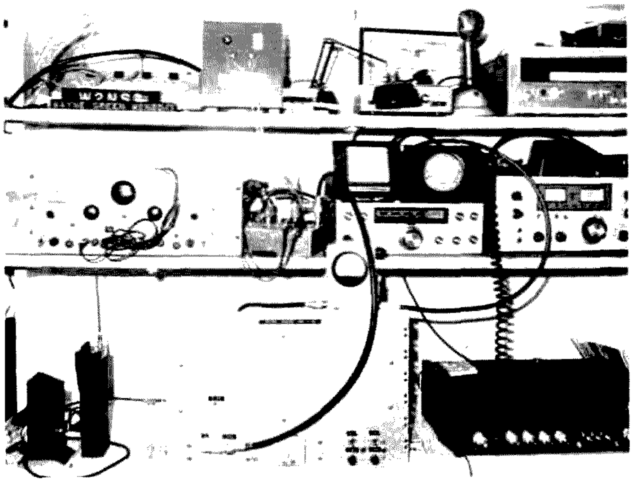
OSCARING

Even though I'm only getting about 20 Watts or so into the 432 MHz antenna, I've been getting a lot of 5x9 reports, so it definitely works. The main frustration about working mode B of Oscar 7 is that there are so few American stations active. Some satellite passes see the 50 kHz segment virtually empty with me in there loud and clear calling CQ, plus maybe one or two CW stations doing the same. W2BLV and W2BXA, should they shut down, would just about empty Oscar on many runs.

On the European passes it is a different story . . . QRM all over the place. I suspect there are more French stations on Oscar than U.S. I've worked 15 countries as of now and have several more to go that I've heard coming through.

Here is my setup . . . it doesn't look like much. It starts out on transmit with the little Ten Tec Argonaut. That feeds on 28 MHz into a Carmichael upconverter with output on 432 MHz. That feeds into a home made 4CX250 amplifier with about 60 Watts emerging . . . that big thing on the bottom shelf . . . used to be the amplifier for WR1ABV on 450 MHz . . . and probably will again one of these days. That goes by coaxial resistor up to an 11 element circularly polarized antenna which stops working when it rains. The antenna controls are on top of the Argonaut, azimuth and elevation. A Vanguard converter is mounted up at the two meter circularly polarized antenna and that feeds down to the Yaesu FTDx-560. A little Sony tape recorder catches the results. The great big power supply on the left is for the upconverter, a tube affair, and feeds it a mundane 250 volts at about 75 mA. The VHF Engineering power supply on the top shelf runs the Argonaut and the Vanguard converter.

I recommend that you do a little work and get active on Oscar . . . it is a ball and we could use another few dozen good signals on it. Some of the



chaps are working out fine with as little as two and three Watts. It isn't easy to get on mode B, but then being difficult is one of the things that makes it fun.

Amsat has announced that G3IOR has earned the Oscar ten district award, having worked all ten U.S. call districts via Oscar. One other interesting news event via Oscar . . . VE2BYG and WB4BWK have linked their microprocessors up via Oscar! Several fellows are working on this project so we can look for a lot more of that to come.

MODE B PROBLEM

Amsat has passed the word that a few of the mode B users of Oscar 7 have been running too much power and it has been draining the batteries. Listening to some of the stations coming through leaves little doubt as to which ops are doing the damage . . . a few signals stand out with rock crushing clarity and you know those fellows are not running any 100 Watts.

When it isn't raining I find that I have a fine signal through Oscar, with most reports running 5x8, and I'm pushing about 20 Watts into the antenna. I can barely hear my CW signal when the antenna is wet.

Amsat suggests you tactfully suggest some lowering of power when you contact one of the superpower boys.

ELIMINATE A HURDLE

Considering the excessive delays in getting license applications processed, an additional hurdle just isn't all that needed. In this case, it is the failure of many applicants through no real fault of their own . . . but due to their study guides being behind the times or not complete enough.

A nice letter from WN5OIC claims that he and his 14 year old son failed the General Class exams because only about two-thirds of the exam material had been covered in their study guides . . . one put out by the ARRL and the other by another well known publisher (not *73*). They now have the *73* General Class Study Guide and they should have no further problems.

If you know of anyone working for a ham ticket, you really should acquaint them with the *73* series of books which are, as far as I know, the *only* study guides which cover all of the technical material you'll find in the exams. Some of the other books are so far out of date that it is incredible. One was written by a ham who has been dead for many years, and even though it is hopelessly outdated the publisher continues to push it. One, written in the 50's, was reprinted again in 1975 and is being sold today through a ham magazine that deserves to remain nameless.

Look up the license study series in the Radio Bookshop ad. Clubs can order in quantity and get a nice little discount if they write to the Bookshop. Orders should be for at least 10 books in any assortment. This helps anyone who is taking a club-given study course to get the books he really needs . . . and the code tapes.

MOBILE ALL BANDS?

Chuck Martin WA1KPS, the chap who runs Tufts Radio . . . New England's largest ham distributor . . . stopped by *73* the other day to see how the Oscar mode B work was coming (we're using his 432 MHz amplifier). He had brought along a long two meter beam to take to the top of the nearby mountain and run checks on how much extra Oscar time and distance operating from another thousand or so feet would give.

The Tufts truck is a car thief's delight, bristling with antennas. But when Chuck calls out "Breaker One Nine" he means the 19-79 pirate repeater, not CB. Chuck is mobile on all ham bands from 1.8 MHz up through 450 MHz. Can anyone beat that?

The Oscar tests? It turns out that Oscar can be heard over two minutes earlier from the mountain top toward Europe than down in Peterborough. There wasn't as much difference to the west, where the mountain was not blocking reception.

RFI BRAINSTORM

While a few amateurs have been pushing hard to get the RFI bill into law, a letter from Ted Chernin KH6GI on the subject made a lot of sense to me. He suggests that here we go again trying to get the government to do something that we could do ourselves . . . without fighting for any bills or waiting for the government to set up a $500 million agency to look into RFI cases.

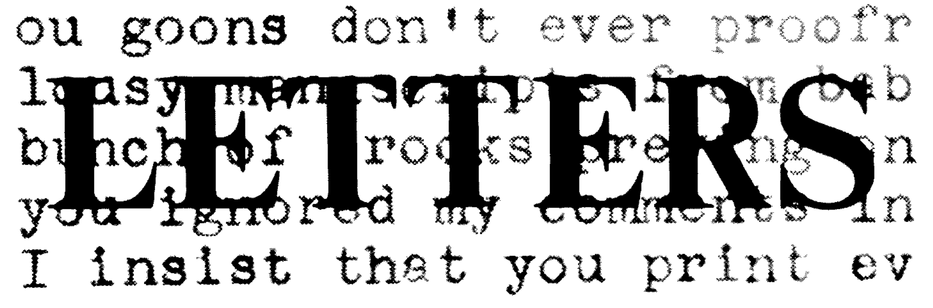
Ted says why not get busy right now and either instead of or in addition to letters to your congressmen, write to the consumer magazines and ask that they include RFI susceptibility as one of their measurements on new electronic equipment such as television, hi-fi, and such.

Further, when you run into an RFI problem, drop a note to your favorite ham rag and ask them to pass the word. If you are able to cure said misery, pass the word (same route) on how you did it. Also, write to the manufacturer.

You might just make sure that dealers are not ignorant about RFI. You'll find that most of them will try real hard to blame the amateur or the CBer if there is interference, not the hi-fi set. He'll tell you just to write to the FCC and get the ham put off the air. Instead of hitting the guy, grit your teeth and explain about how these things are.

Consumer Reports, Box 1111, Mt.Vernon NY 10550, if you feel like

Continued on page 12



UP THE CREEK

Boy are you guys up the creek! Me an' my good buddy the Duster were mobiling easy up I-75 when we saw the biggest cotton-pickin' mobile antenna ahead ever seen! Well, we tried to modulate with him on 19 but he wouldn't copy.

Then Duster noticed a decal on his bumper that said, "Hang it up, CB! – Be a ham!!!"

Well we-all got rightly upset at him so we followed him into a diner along the way. We confronted him and he explained what a mess CB is and how he started reading *73* and before he knew it he had sold all his CB stuff to some trucker from Ohio and bought all kinds of amateur equipment. Duster an' I went over to a radio store and asked about classes at the local high school . . . and what do you know??? Now we're selling all of our CB things!!!

Amateur radio is really easy; I can't remember when I *didn't* know most of the questions on the Novice test! The code's a bit tricky but no real problem there.

What I would really like to know, is, how come I don't talk funny anymore?

HEARTBREAKER?

I have a problem which *73* may be able to help me with.

October 23, 1975 I had a Kordis heart pacemaker installed or implanted. The doctors told me that I could not use a power lawnmower, electric razor or any power tools which have a magnetic field revolving.

Since the pacemaker can be controlled magnetically and also electronically, it becomes evident that the antenna which runs into my heart could pick up harmonic frequencies which would put the pacemaker in a passive mode.

I have written the Kordis Company and a spokesman for the company called me on the phone from North Carolina and gave me some of the things I could not use, but he had some reservations about harmonic frequencies.

What I need to know is whether *73 Magazine* could ask its readers if any of the amateurs who read it could give me the names of active amateurs who have pacemakers and whether they have any deleterious effects from radio.

One of the things which the Kordis people told me that would deactivate the pacemaker was a pulsed signal.

Since I work mostly CW, I am not

active at the present time. I do not expect any person to stick his neck out, but would appreciate the names of persons I can contact by phone who qualify as recipients of pacemakers and are amateur operators now active.

UNBELIEVABLY GOOD

The service from S.D. Sales is unbelievably good!!!

A clock kit ordered on 22 November 1975 arrived here on the 28th, and was operating that evening. Further, when I wrote S.D. Sales that one segment of one of the 7-segment displays was weak, they sent me three (I) FND-70 LED replacements. Free!

Amateurs have always demanded high quality components and fast service. What is unusual today, however, is to find a company which provides both. S.D. Sales is such a company!

GRAND OPENING

I would like to report to you guys on the 2 meter opening which came through this area on the weekend of Dec. 6 and Dec. 7.

This opening lasted about 48 hours, working through the Mena, Arkansas Repeater, which is on .19-.79. The repeater's call is WR5AEM. It is located at the top of Rich Mountain at an altitude of about 3000 feet above sea level. It has an operating output power of about 25 Watts.

On this weekend there were 14 states working through this repeater. They were the following: Arkansas, Louisiana, Mississippi, Alabama, Kentucky, Tennessee, Indiana, Illinois, Iowa, Missouri, Kansas, Nebraska, Oklahoma and Texas.

We would appreciate you making the public aware of this opening.

Howard Holmes WB5NWV
De Queen AR

NO

I propose a standard color-coding system for mobile antennas so that one mobiler could quickly visually tell what band another mobiler was operating at that given time: 80 – grey/black; 40 – yellow/black; 20 – red/black; 15 – brown/green; 28 – red/grey (standard color codes).

The two colors could be colored tape (or paint) around a loading coil, could be put on a small "flag" at the top of the whip, or could be just 2 tape strips on a bumper.

How about it? Will you suggest it?

Ray Day WB6JFD
Palos Verdes CA

No – Wayne.

MAYDAY!

Enclosed is a memorandum from my log of a mayday that was received by JY3ZH, Zeedan Hussen, and myself 28 Nov 75.

Following is information I have been able to get from US authorities here in Germany and G3YPK in England.

1 Dec 75 I called US Air Force Europe, Air Rescue Service, Ramstein, Germany, trying to find out any information about W2ACS/MM. I was told by Major Bowen that the Air Force and Navy out of Italy had flown a total of 60 hours without any success. They also said they called the FCC trying to confirm the callsign W2ACS/MM. The FCC told them they had no record of the callsign ever being issued. They also could not find any information on the ship SCORPION.

G3YPK in London, England, notified the British Defence Ministry. G3YPK called me by telephone the 29th of Nov 75 saying the Defense Ministry had verified the callsign W2ACS/MM. They also could not find any registration on the ship SCORPION. I later found a 1956 callbook and found the call W2ACS.

I have tapes of the mayday that were sent to me by G3HAS from England. They are not complete but I can send a copy to you. They are of very poor quality.

There have been numerous rumors on 80 and 20 meters that W2ACS/MM was picked up. However, I cannot get US Air Force authorities in Ramstein, Germany to confirm this.

I realize that there is and will be a lot of criticism on how I handled the net but I'm up to it.

This is the first emergency I have ever encountered and now that it's over I know that if it ever happens again I will handle it much differently. I am better prepared.

At this point many amateurs in Europe are beginning to have their doubts about the mayday. There is widespread speculation that it was a hoax.

In a way I hope it was. I wish no one in the situation W2ACS/MM was in. The thing that bothers me is the way many amateurs here in Europe treated the mayday as a big joke. Contact with W2ACS/MM was lost many times due to interference (QRM) from many amateurs.

The upper 10 KCs of the 80 meter band is considered by a gentleman's-type agreement to be for DX only. Many operators tried to make us QSY because of this and when we didn't, caused considerable QRM. Many Europeans did not even know what a mayday was.

Myself, Zeedan and G3YPK managed to maintain control of the frequency for 7 hours. Many transmissions from W2ACS/MM were lost due to the QRM.

Would it be possible for you to investigate or turn this over to the FCC, since a US call was used? I do not know what to do. W2BFI Manuel R. Gonzales referred me to you. He is stationed here in Ansbach, Germany also.

Memorandum For Record:

Subject: Distress MAYDAY call received by DA1EK, 22: 5, GMT, 28 Nov. 75, from W2ACS/MM.

1. Reference: a) United States Army Technical Manual 11-490-7, with change 1. b) Laws Concerning Amateur Radio in West Germany. c) Federal Communications Commission, (FCC). d) Radio Amateur Law of 14 March 1949.

2. This is a memorandum for record to the log of DA1EK/WB5NDW/AE1EK.

3. Following is the information that was received from W2ACS/MM by this station, DA1EK, to the best of my knowledge. a) Date and Time: 28 Nov. 1975. 2:05 GMT, thru: 9 Nov. 1975, 07:15 GMT. b) Frequency: 3.793 and 3.796.

4. On the dates and times above this station received a MAYDAY distress call from: a) STATION: W2ACS/MM. b) NAME of OPERATOR: Tom Hapasig. c) LOCATION: 33.52 NORTH, 31.23 EAST. d) SHIP'S NAME: Private Vessel SCORPION. e) WEATHER CONDITIONS: Three to five foot waves; overcast skies; very low ceiling: light winds; no rain. f) Ship was taking on water fast due to a section of the mast breaking off and falling. The mast section punctured a large hole in the fiberglass hull. g) A total of five persons were aboard, which included his XYL h) All Maritime emergency equipment had been lost. The only thing left was a Collins Transmitter (Amateur Gear), one portable emergency beacon, five life vests, and a life raft.

5. At approximately 22:20 GMT, 28 Nov. 75 this station, DA1EK, relayed by telephone the above information to the 1st Armored Division Staff Duty Officer, Capt. Trahey. He in turn notified the Emergency Action Officer at USAREUR Headquarters, Heidelburg, Germany.

6. The following Amateur operators took action to contact the proper authorities in their countries (as well as many others who I was not able to copy down due to the confusion and interference at the time). a) JY3ZH-JORDAN b) 4Z4FW-ISRAEL c) G3YPK-ENGLAND d) I2BYE-ITALY e) DA2AS-GERMANY f) DA2UD-GERMANY g) DA1GW-GERMANY h) G3ALI-ENGLAND i) G3HAS-ENGLAND j) G4CKL-ENGLAND k) GW3PDW-WALES l) GW3AX-WALES

7. Messages were relayed to W2ACS/MM from DA2UD by this station, DA1EK, concerning actions taken by US FORCES Rescue Parties. DA2UD had contact with a rescue operations center. Any information concerning these messages should be directed to DA2UD through the USAREUR MARS Director.

8. This station, DA1EK, was directed by W2ACS/MM to pass traffic for him. This station, DA1EK, then assumed emergency net control.

9. After many hours of work and long distance phone calls, G3YPK in England confirmed that W2ACS/MM was a legally licensed operator.

10. G3HAS in England notified this station, DA1EK, that he had everything down on tape and would send a copy as soon as possible.

11. Contact was lost with W2ACS/MM at approximately 03:30 GMT, 29 Nov. 75.

12. The above information is true to the best of my knowledge. There were many confusing moments due to the few Amateurs who thought it was a big joke.

13. In the opinion of this station only, DA1EK, I feel that the European Countries Governing Amateur Radio Service and Licensing should monitor and take action against those Amateurs who continually send unauthorized transmissions such as: a) Transmitting music and other commercial signals. b) Emission of unmodulated or unkeyed carrier. e) Require all Amateur stations to have and use a Dummy Load. f) Emission of spurious (SPLATTER) over 3 KCs. g) Establish laws concerning interference with a station who assumes net control with a distress MAYDAY call. h) Stop the gentlemen-type agreements and establish regulations concerning them.

14. All of the above caused confusion and almost panic on the part of W2ACS/MM. This is also the type of thing that the serious Amateur must put up with and look forward to every day.

STRANGE

Isn't it strange that the league (ARRL) did not tell me when the Section Communications Manager ballots would be sent to voters in the Illinois section?

Isn't it strange that the current SCM knew well in advance so that he could plan his campaign?

Isn't it strange that I was told that the ballots would not be counted for a couple of weeks after the end of voting, and then was sent the results only 2 days after the voting deadline?

Isn't it strange that my request to the ARRL for finding out how many possible voters there were in that election (not names but a number) was unanswered?

Isn't it strange that many possible voters in the Chicago area (where I live) never received ballots?

Keeping Up With the State of the Art: What It's All About

. . . if a man neglects to keep abreast of his time, he yields the right to butter his bread with the milk of the Yak. – E. Haung-Ti

A few years ago, there appeared in *73 Magazine* an article which I ingeniously wrote entitled, "How I Read the Radio Amateur's Handbook and Found Happiness."

For the unlucky few who didn't read this incredibly clever piece of literature, or for those who did and can't remember, I will briefly summarize: First, I artfully described the anguish I suffered from knowing so little about electronics while trying to function in a social order that is at least 99.9% ham. I explained how miserable I was because I couldn't discuss capacitive-reactance with my wife. Then, with uncanny writing skill and insight, I gave both the remedy for my malady, which – in short – was reading the *Handbook* from cover to cover one Thursday night, and the result of my remedy – I could then talk freely about Ohms and Amps like Mac at Mac's Variety.

I have put those years to good use reviewing what I thought I had learned from reading the *Handbook* and have come to the conclusion that my comprehension of the state of the art at that time was not exactly what you would call keen.

Now, after so much time and investigation, I can see how ignorant I was. I can see how foolish I was to have come on so strong with so little ammunition. What a fool you must have thought me. You were right, I was a fool. But I know now where I went wrong. I have learned. For example: I'm embarrassed over the fact that I ordered a few dozen microfarads from the Radio Shack. I realize now that those guys at the Radio Shack were laughing *at* me, not *with* me. I now realize that the dipole I put on my roof needs a rig for it.

Those were bad days!

But like I say, that's all changed now. I've seen the light. I have learned what electronics is all about. Instead of waddling, eyes closed, through the mammoth sea of ignorance, I have courageously peered through the window of knowledge and astutely grasped all the what-once-were-difficult concepts that govern the complex world of electrical phenomena.

It's a thrill to be totally cognizant, to be aware of that broad definitive line that separates knowledge from ignorance, and what's more . . . *to cross it.*

Contrary to what some philosophers might propose, *awareness* is bliss.

I now understand the world of electronics. I have a thorough working knowledge of all its component parts, its idiosyncrasies, its seemingly enigmatic behavior patterns, its wonders. I'm on top of it. Aware. The reason, you see, is that I've read another book.

Well, actually, it wasn't really a book, it was more like a magazine. *Electronics Stuff* or *Build Your Own Electric Things* I think it was called. Whatever its name, it certainly was a wealth of information, a real education.

There was one article in there that described just how to go about building an electric spoon. Another had complete instructions (including the schematic) for constructing a device that detects the whereabouts of pine cones. If I'm not mistaken, I think it was called a "pine-cone detector." Another project – and one that really interested me a lot – was building a multimeter, and I probably would have gone right ahead and built one if it wasn't for the fact that I didn't have any multies in the house at the time and therefore no need to meter them.

But I'm getting away from the subject.

The subject is of course that by reading a *second* electronics book, I have taken one step toward keeping abreast with the state of the art, which I now realize is all important.

What good, when you stop to think about it, is a doctor who, while in doctor school ten years ago, learned a lot about bellies and heads, but hasn't read a single journal or some other kind of doctor book concerning those two vital body parts since? State of the art . . . that's really what it's all about.

Yet, you'd be amazed to find out how many so-called knowledgeable, seemingly competent, well-known champions-in-their-field-type people there are who *haven't* kept up with the state of the art.

Example: Miss Graham, my third grade grammar school teacher, who, I was convinced, knew everything there was to know in the whole world, for one entire school year insisted that "knowledge is power." Obviously, Miss Graham knew nothing about wattage.

Another more amazing example was a man with whom we are all familiar, admired, a man whose ideas helped shape the world into what it is today, a man who was truly a genius, a giant in his field. But a man who made one fantastic error that has gone undetected for decades. Of his oversight, his lack of knowledge and the reason for it, I am now aware. This man, you see, giving him all the respect due him, could not possibly have kept up with the state of the art and still proposed what he proposed.

I'm referring of course (if you haven't already guessed) to none other than Albert Einstein. And the error I'm referring to is this: For a quarter of his lifetime, Albert Einstein, scientist, mathematician, philosopher, suffered under the illusion that voltage . . . get this . . . was equal to mass times the speed of light squared ($E = mc^2$).

WOW, CAN YOU BEAT THAT?

Finding this out was like being ten years old and discovering that Johnny Weismuller couldn't swim. WOW!

How could this be? How could this man in all his wisdom and glory actually believe that? Do you realize that he built his entire relativity theory on that?

The sad fact is, both Einstein and Miss Graham were wrong. They were wrong not because they were stupid – neither was stupid. I didn't know Einstein, but I'd bet a week's pay that *he* wasn't stupid. Yet . . . and yet, they were both wrong. Why?

As I see it, they were wrong for one reason and one reason only, and that is simply that neither Mr. Einstein or Miss Graham kept up with the state of the art. And it's as simple as that. (I've often wondered if Einstein and Miss Graham knew each other.)

Not to belabor the point, but Einstein not only neglected to keep up with the state of the art, but completely ignored the *Handbook*.

So like I say, as you can probably see for yourself by this time, keeping up with the state of the art is all important.

The question now arises, of course, as to how to keep up with the state of the art.

Simple. Collect the two magazines I've read, or if you want to go overboard, maybe even a few more. For the real state of the art freak, there are also correspondence courses, but I figure you've got to be realistic and draw the line somewhere.

No matter how you cut the pie, whether it's two magazines or two thousand magazines, there's a lot of learning to be done. The directions in which modern technology has taken us are pretty hairy to say the least: JFKs, flip flips, AND and ARE gates – who knows where it's all going to end. Not to even mention digital logic, which is a whole other bag of worms.

The road is tough, but to really stay on top, to really know what's happening, to really know what it's about, the road must be followed. To do so is keeping up with the state of the art, or, if you prefer, "buttering your bread with the milk of the Yak." And *that,* my friend, is *really* what it's all about.

Panorama City CA 91402

"Good-Guy, the Gold-Plated Radio" — that's the final title assigned to the latest "epic production" soon to come forth from the Palisades Amateur Radio Club motion picture staff. As regular readers will recall, about a year ago I mentioned that we were documenting on film all the events surrounding the acquisition by PARC of their new MICOR Repeater and Stationmaster Antenna that was to replace the old "A" strips and J-Pole that had served PARC quite well for many a year.

The main reason that I mention this now is due to the many inquiries as to when the film would be available for showing to interested groups in other areas as well as out here. It looks as though late April would be a fair guess, since we have finally gotten into the most important aspect of filmmaking — that of post-production. At the moment, there is about 1800' of Super 8 mm film that must be edited into 28 minutes of story complete with a happy ending. There is also a musical score to add, narration to write, and umpteen other details that I personally know little about. This enormous task is being undertaken by one of the finest professionals in the motion picture industry, George Hively WA6YEA. Those of you who saw "The Longest Yard" in theaters or the TV program "Thrill-seekers" have already seen a sample of George's expertise. Amateur clubs that have seen the first PARC film "Field Day 71" have gotten the chance to see how a true professional like George can build an excellent story from a few hundred feet of assorted home movies. PARC is lucky to have a George Hively as one of its devoted members, but I too am lucky to have a friend such as George who has taken the time and has had the patience to share some of his knowledge with a neophyte filmmaker such as yours truly. Without this beautiful guy, I doubt if I would have had the guts to take on the project of "Good-Guy, the Gold-Plated Radio." Friendship — to me that's the true meaning of amateur radio.

To answer some of the questions that have come in concerning the film, let me give you the following information. Originally, we had hoped to do this film in 16 mm with an optical soundtrack. When I found out what that format would cost, it was decided to revert once again to Super 8 mm. In the meantime, a number of camera manufacturers have introduced a line of Super 8 mm sound-on-film cameras and projectors. Unlike 16 mm, Super 8 mm is a magnetic rather than optical sound system, and the recording technique used is identical to that of any tape recorder. If you have a camera that is capable of recording, film is available that is pre-soundstripped and you can record lip synchronized sound as you take the picture. The other alternative is to shoot silent film and then have the soundstrip added at the time of film processing or after editing, as it will be in our case. We chose the latter method since I already owned two fairly decent Super 8 mm cameras and our sound track (narration plus music) won't be added until after all other post-production work is done. It was just plain more economical that way, since most of the aforementioned 1800' of film will be discarded when we boil it down to 400' of finished product. Therefore, PARC invested in a GAF Super 8 mm Sound Recording Projector rather than a sound camera, as we figured that for us it would be more beneficial. Already, the sound track for "Field Day 71" has been recorded on the film so that lugging a tape deck, amplifier and speaker with us to show it has become a thing of the past. Also, PARC can now mail out this film without providing a detailed instruction sheet as to how to synchronize the sound with the picture, and more important, how to keep them together throughout the film. Having run it many times, I can tell you that it was no easy job. "Field Day 71" is still available from PARC free of charge by sending a letter to the Palisades Amateur Radio Club of Culver City, PO Box 2453, Culver City CA 90230. Please mark the envelope to my attention and use the words "Film Request" on the envelope. Also, please be patient, since there is only one distribution print of this film at this time and there is a waiting list.

What the foregoing leads to is this. In a day when amateur radio must do everything possible to garner good public relations, a relatively inexpensive means to that end is now at hand, thanks to the advent of Super 8 mm sound-on-film photography. For about $450, the price of a synthesized two meter radio, your club can have the basic tools to produce your own films about amateur radio and how your particular organization fits into and serves your community. You have the ability to produce your own public service announcements about amateur radio that can be aired by any TV station equipped to run Super 8 mm magnetic sound film. (I suggest that you first check with your local TV outlets before doing the aforementioned to be sure they have the facilities to put what you produce on the air. While more and more stations are obtaining Super 8 mm film chains, not all are so yet equipped.) Even if you just want to document club happenings for club use alone, the added dimension of sound adds so much to a film. Again, this is one of those adventures limited only by your own imagination. In coming months I will try to give some more ideas on the use of this medium to improve the public image of amateur radio. In the interim, if you have any suggestions along these lines, pass them along to me and I will get them into print for you, here in Looking West.

Were you or better yet your children lucky enough to catch the children's program ISIS on Saturday, November 15th? If you did, then you caught the episode titled "No Trumpets — No Drums," written and produced by Art Nadel W6TZY. The story dealt with the "good people" discovering the hiding place of the "bad people" in a ghost town. Though our "good people" are discovered by the criminals and held semi-captive as the "bad people" prepare to escape, one of our co-heros is an amateur who has a TR-22 in the car. He is able to sneak back to the vehicle, retrieve the radio, make a few quick repairs to it (it was intermittent in an earlier scene), and use it to summon help. In the end, amateur radio and the law will out and the criminals are captured.

Sounds a bit corny you say? Sounds basic and childish? Well, remember it was a program designed to be viewed by children and to both teach and entertain at the same time. In regard to the latter, Art went to great length to carefully yet simply explain what amateur radio was and even how one became a member of our amateur community. He does this by having his lead character, a high school student, explain the difference between amateur radio and other radio services to a teacher that is judging his "Science Fair" type project based on a demonstrating amateur radio. He demonstrates the utility of international Morse Code as one of amateur radio's communication tools a bit later when our high school student has an auto accident and is trapped in his vehicle half way down the side of a hillside. Our amateur/hero taps out SOS on his auto's horn. Luckily, the super heroine of the series, ISIS, comes to his rescue and, using her super powers, saves not only him, but his vehicle as well.

Not long ago, in this very column I stated that I felt it would be today's children that would hold the key to the future of amateur radio, and that we as today's amateurs had an obligation to see that they were educated as to what challenges were offered by becoming amateur radio operators, and had their imaginations stimulated enough to take steps in that direction. If you agree with me, then the work done by Art Nadel W6TZY in "No Trumpets — No Drums" is definitely a giant step in that direction. Therefore, this is my personal and public letter of thanks to him and his staff for one heck of a good job, and I sincerely hope that he and others in the same profession with access to the mass media will continue in that direction. If we can stimulate America's "little people," offer them the imaginative challenge to be found as members of the amateur radio community, then we can insure a bright future.

Another program that will be treating amateur radio in a favorable light will be an upcoming episode of the TV adventure series "Harry O," tentatively titled "Book of Changes." While details are still sketchy on this one, I have been told that we will be treated in a very favorable light and most important, on the side of the "good people." More on this as soon as information and an air date is available.

One thing I would like to suggest. If you decide to write to the networks complimenting them on such programming as this, don't be picky about technical details. Don't write letters telling how much you enjoyed the program and then go into a five page tirade because this was not correct or that didn't seem perfect. Remember, you are dealing with an entertainment media and there are two things to be considered. First, not all TV script writers are licensed amateurs, and in fact, I suspect that very few are. What they know of our hobby they have learned either by accident or through necessity. Maybe one of these people was stuck on a freeway and an amateur stopped to offer assistance, or the guy has a neighbor involved in amateur radio. Either way, in most cases their technical knowledge of amateur radio is usually limited, so let's be thankful for the fact that they are now treating

us as an asset to society rather than a liability.

Also it is important to remember that TV is basically an entertainment vehicle and that what is shown must be easily understood by the general public without their having to run out and locate a copy of the Rules and Regs along with an FCC official to interpret them. If the dialogue sometimes sounds cornball, or if you wish that the QRM level on 20 was as low in real life as it is on the tube, remember you are being entertained along with millions of other people. Most important, TV production companies are beginning to realize the viability of amateur radio and are starting to integrate it more and more in a *positive* way into their programming. Perhaps my dream of having the title "amateur radio" as household words, understood and respected by all, will become a reality yet. At least the seeds have been planted.

Television has two basic jobs in my opinion – that of education as well as entertainment. There are times when it is possible to totally integrate the two, as in the case of Art Nadel's "No Trumpets – No Drums," and there are also times when the educational aspect takes a back seat to the entertainment aspect. Conversely, there are also times and places when entertainment can take a back seat to education, and such is my latest project. I am trying to produce the world's lowest budget educational television program, and if I am lucky I might just pull the whole thing off. I am planning a one hour informal roundtable discussion between amateurs of varied interest backed up by color slides and remote interviews utilizing what I have learned about Super 8 mm sound photography to keep the cost of these "remotes" to a minimum. Thanks to the technical staff of Public Broadcast Station KVST, things are beginning to take shape and a finished vehicle may be ready for airing by late March or early April.

The moderator and guests will all be amateurs, and the purpose of the program will be to explain in simple, non-technical language who we are and what we are all about. We will show amateur radio as a hobby, as an educational tool, as a method of communication in times when no other form of communication exists, and as a therapeutic tool in the recovery of people from serious illness. The whole project started almost a year ago when one of the KVST staff members attended a PARC meeting (the fellow is an amateur) and happened to see the field day film. He asked me about getting it to air on their station, but for reasons beyond our control that was not possible. We did chat, however, about putting together a program about amateur radio and the matter sort of died at that point. I was too busy filming "Good-Guy" and writing to get involved in anything else. Then two events took place. "Good-Guy" was "in the can" ready to be edited by George and I happened to run into Chris WB6HGW, another KVST staff member, at about the same time. My conversation with Chris led to further conversations with others on the subject and out of all this has come "Amateur Radio's Wide Horizon," my tentative title for the program. You may ask what a TV service technician such as yours truly is doing producing a TV program. Well, someone has to do it or it won't get done. For me it is a learning experience as well as doing a bit more to help publicize amateur radio. Whether it will ever get aired I cannot be sure at this time, but if it does, it will probably be the first program of its length done for about $99.95 or so. Talk about low budget...

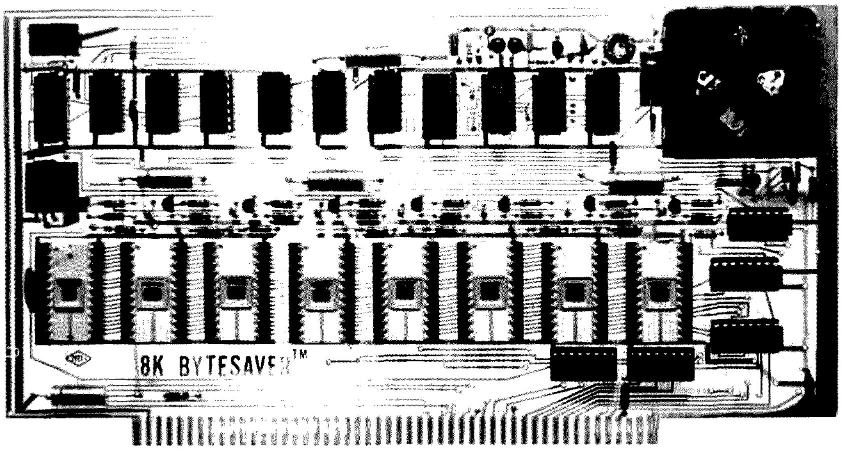
About two weeks ago, the formative meeting of the Southern California Amateur Radio Public Relations Committee was held to get the ball rolling toward obtaining some good "PR" for our amateur radio community. Chaired by Lenore Kingston Jensen W6NAZ, the 40 or so of us that attended the meeting spent about three hours discussing the many various ways that we could obtain media coverage for our many varied activities, and more important, what form of media coverage was best suited to a given event. In forthcoming issues, I will go deeper into some of these, but for the present let me just cover the major accomplishments of the evening. First, it was decided that we would produce and distribute a simple PSA (public service announcement) that would briefly explain what amateur radio is and provide a telephone number and addresses where more information could be obtained. Something simple and inexpensive like a few color slides with about 30 seconds of copy to be read by an announcer or put on a tape cartridge. Inexpensive but effective.

Next, a Public Relations Net was formed that now meets through the facilities of the WR6ABN repeater system (147.82/.24) every Thursday evening at 7:30 pm local Pacific time. Its purpose is to take inputs on newsworthy amateur radio events and channel them through Lenore to the proper media sources for dissemination to the general public. It is urged that *every* radio club and repeater organization in Southern California appoint a public relations spokesperson to this committee and have that person check into this net hosted by Burt WA6MQV. A low-band net on 75 or 40 is also being discussed so that those people outside the coverage area of WR6ABN can also take part in this truly worthwhile program.

If your group happens to fall into the latter group (that which is not within the coverage area of the WR6ABN repeater system) and you wish to take part in this ongoing public relations program, a program that may well help insure the future of our amateur radio community, then drop a line to Lenore (she is listed in the callbook) or to yours truly and I will channel such letters to Lenore. Next month, I will continue with what I promised for this month; the Ventura Convention and the SCRA meeting wrap-up as well as more on what began here in the field of amateur radio public relations about two weeks ago.

In the interim, if you in other parts of the nation want to get started in the same direction that we are taking here, I will be happy to share what knowledge I have garnered with you either through personal communication, or if it keeps growing, through a series of articles apart from Looking West. It's up to you. I will write them if you will provide the inputs. True, we have made a great beginning, but there is yet a long road to travel. Working together both locally and nationally we can achieve that goal. We can achieve public recognition, and more important, public respect. It simply takes each of us doing his or her share. I believe we can.

NEW PRODUCTS



BYTESAVERtm

Cromemco of Los Altos, California has a nice gadget for use in the Altair 8800 computer . . . it's an 8K PROM board designed to plug right into the Altair and it has a built-in programmer for the PROMs.

This is an excellent way to keep, say, the 8K BASIC program right on tap for the Altair, ready to use immediately when the computer is turned on. After a few dozen times of hand switching in the 19 step loader and then playing the five minute cassette loader for BASIC, you'll be ready for a ROM memory for the works.

In addition to making the start up of the Altair duck soup (to coin a phrase), there is a little matter of keeping the program in good shape. Little glitches in the power line come along and knock out some of the RAM memory now and then, introducing errors into the program with the result that in ordinary operation you have to refresh the program every now and then by starting over and running it in from tape. With the program in ROM it won't deteriorate.

Then, one other factor, the cost of the memory alone. The Bytesavertm costs $195 in kit form vs. twice that for the Altair 8K in dynamic RAM.

Cromemco, 1 First St, Los Altos CA 94022, if you want more details.

Autobiography of an Ancient Aviator

Brooklyn NY 11230

HOTEL RANGES AND A REAL CLOSE ONE

I had just returned to Brooklyn from a six month Air Service active duty tour at Langley Field, Va., so the first thing on my calendar was to get a job. I could go back to selling Hupmobiles but that was a dead end street. My father-in-law told me that the Michigan Stove Company of Detroit was looking for a man to handle their hotel and restaurant kitchen range business (wholesale) in south New Jersey, Pennsylvania, Delaware, Maryland and D.C., with headquarters and warehouse at Philadelphia. So I phoned, made an appointment, and went to Detroit to see about the job, since nothing worthwhile was doing in the aviation business. They offered me the position with a good salary and liberal traveling allowances, and I accepted. The next ten days were spent at the factory familiarizing myself with the various products I would be handling, getting all the information I could about the firms and people I would be dealing with in the territory, and all available information about our one competitor and its products.

It took me awhile to get acquainted with the hotel supply house and gas company salesmen as well as the chief chefs in the larger hotels and restaurants. Regular calls on these and A & E firms doing plans and specifications for new hotels in my territory produced a good flow of business. Detroit was happy.

One very lucky experience comes to mind. I was just finishing breakfast one morning in Atlantic City when the fire sirens sounded. I walked up the boardwalk to see where the fire was. It happened to be in the rear of one of the larger hotels in town — right where their kitchens were located. The fire was brought under control very quickly but it had gutted both the American plan and European plan kitchens. I knew the head chef so I found him and told him that I had all the equipment to put him back in business at my Philadelphia warehouse and could have it shipped out that afternoon. Then, with the gas company's help, I could start installation as soon as he could get the debris cleaned out. I got the Atlantic City Gas Company representative over and he, the chef, and I made up the new kitchen layouts. The old equipment had been in use for about 12 years so the hotel manager thought this was a good time to install new ranges, etc.

> **Ralph claimed to be the only man to bite himself in the behind . . .**

(fire insurance, you know). Anyway, the gas company got its order, I got my order from them, and had the ranges on their way that afternoon. The importance of the order can be gauged by the fact that the gas company man (a noted tightwad), who worked on a salary plus commission, took me to Hartney's that evening for a lobster dinner. Detroit also came along with a nice raise.

One of the trips I made for the stove company was to Dayton, Ohio. Several of my Kelly Field classmates were stationed at McCook Field, near Dayton, so we got together for a reunion. They brought along Ralph Lockwood, who was chief test pilot at McCook. Ralph claimed to be the only man to bite himself in the behind. He said it came about like this: He had false teeth that didn't fit very well so when he was getting ready to take off for a test flight he would put them in his rear pants pocket. This day he parked his teeth, put on his parachute and took off. About 1000 feet over the field the engine blew up, taking a lot of the front end of the ship with it. So Ralph bailed out. When he hit, it was at a pretty good clip. He landed on his gluteus maximus with his false teeth making his only wound. He swears that's what happened.

In 1927 I was on active duty at Mitchel Field, L.I., the last two weeks in July. On my way home from Mitchel I stopped by at Curtiss Field to visit some of my friends there. While we were talking, Casey Jones came over and said he had a photo mission over Manhattan and would I like to take it. I said I'd be glad to help out so they rolled out an old C-6 Standard, put the photographer and his cameras in the front cockpit and away we went. We were only a few minutes out of Curtiss and over New Hyde Park when there was a fair-sized explosion up front, no more power and the ship became quite tail heavy. Then I saw that we had a pretty good fire going up forward where the six cylinder engine block had been. The gas tank in this ship was in the center section over my passenger. There was a petcock in the gas line from the gas tank to the engine and I tried to get the passenger to turn it off and stop feeding gasoline to the fire. The fellow was too scared to move, so, as the flames blowing back were getting pretty hot, I had to side slip to keep them away from the fuselage. There was not much choice as to landing place, so I slipped to within a few feet of the ground and landed in a small potato patch. By that time the right wing was burning briskly, so I hauled the photographer and his cameras out of the front cockpit just before the gas tank exploded. A water pumping station was nearby so I borrowed their phone to advise Curtiss Field of the good news: one Standard they wouldn't have to scrap. Ed Conerton came over to pick us up. When we got back to Curtiss, I offered to take the young man on his mission in another ship but he was too badly shaken. So Ed and I retired to a nearby speakeasy to freshen up a bit. I later learned that the C-6 engine block that left me without warning landed in a service station in New Hyde Park but did no damage — just scared them.

A few days after this I received a wire from Lockwood, who had joined the newly-formed Aeronautics Branch of the Department of Commerce, asking me to come to Washington to talk about joining them. The next week I went down to see what was going on.

In 1926 Congress passed the Civil Aeronautics Act, under which was established an Aeronautics Branch in the Department of Commerce. Its function was to exercise a certain amount of control over civil aviation by means of licensing pilots, mechanics, aircraft and engines. William P. McCracken was appointed Assistant Secretary of Commerce for Aeronautics, and Clarence M. Young, Director of Aeronautics. With the help of Gil Budwig, Dan Scarritt and Ralph Lockwood, they were in the process of recruiting a group of qualified inspectors to do the examining and testing for the licenses.

They offered me the job as supervising inspector of their no. 2 region, which consisted of south N.J., Penna., Del., Md., Va., W.Va., N.C., and D.C. The salary was less than I was getting with the stove company, but the job was important in aviation and I figured it would put me in contact with some of the top people in the business. While I was there I got my transport pilot license (#73) and also an aircraft and engine mechanic license. I agreed to start work for them on November 1. That meant moving my family (Cleo and Wayne) to Philadelphia, where my headquarters would be.

Next month I'll tell you about my 15 months as a Supervising Inspector during the aircraft engine transition period from 0X5s to the new radial engines. Hold on.

HAM HELP

I can offer "Ham Help."

Donald A. Huettl WB0MBY
11349-6th St. NE
Blaine MN 55434

I have written you before about how difficult I and others like myself who have not had an electronic background have found it to get help to become a ham. Your tapes have been very helpful to me. In fact, I took my Novice exam Wednesday, given to me by Al Cook WA1RIT (hope I passed).

Help by hams is hard to find, almost as hard as finding hens' teeth. Thanks to Bill Loeffler W1PFA, owner of Camercraft of Lawrence, Mass., Bill Longworth WA1HWE, John Scofford WA1OAQ, and all others who organized amateur radio classes at Salem H.S. This class consists of males and females, young, middle aged and older folks. This class started with about 60 and still has over 50 attending. I will try to send a picture of the class when the class is graduated.

Keep up your help column and list other hams' names who really want to give help.

I'm hoping the FCC will soften the theory part of the exam, but I believe the code should be required and ten (10) wpm should be required on all exams.

Basil W. Polinchak Sr.
Andover MA

CONTESTS

Editor:
Robert Baker WA1SCX
34 White Pine Drive
Littleton MA 01460

Please be sure to send all contest information to WA1SCX at least 3 months prior to the event's date, so that we can be sure to get it included before the publication deadline.

ARRL NOVICE ROUNDUP
Starts: 0001 GMT Saturday, February 7
Ends: 2369 GMT Sunday, February 15

The contest is open to all amateurs in any ARRL section. Operating time must not exceed 30 hours total during the 9 day period while off periods may not be less than 15 minutes at a time. Times on and off must be entered in your log. Crossband contacts are not allowed. Novices may work anyone while non-Novices must work Novices only. Each station may be worked only once regardless of band.

EXCHANGE:
RST and ARRL Section.

SCORING:
Each completed QSO counts one point. The total multiplier is the number of ARRL sections and foreign countries worked. VE8 counts as a separate section. The final score is the number of QSO points plus your ARRL Code Proficiency credit (15 wpm = 15 pts.) times the total multiplier.

AWARDS:
Certificates will be awarded to the highest scoring Novice in each ARRL section. Multi-operator or higher class licensees are not eligible for awards but the top ten scores will be listed in the results.

LOGS:
Use official ARRL forms available from: ARRL, 225 Main St., Newington CT 06111. All entries should be sent to this same address.

Please check the January 1976 issue of QST *for any last minute changes in rules or operating times.*

YL-OM CONTEST
PHONE
Starts: 1800 GMT Saturday, February 21
Ends: 1800 GMT Sunday, February 22
CW
Starts: 1800 GMT Saturday, March 6
Ends: 1800 GMT Sunday, March 7

Sponsored by the YLRL, the contest is open to all licensed operators throughout the world. All bands may be used but crossband operation and net contacts are not permitted. Phone and CW contacts will be scored as separate contests, so please submit separate logs. A station may be contacted no more than once in each contest for credit.

EXCHANGE:
QSO number, RS(T), and ARRL section or country.

SCORING:
One point is earned for each station worked, YL to OM or OM to YL. Multiply the number of contacts by the number of different ARRL sections and/or countries worked. Contestants running 150 Watts input or less on CW and 300 Watts PEP or less on Phone may multiply the score by 1.25 (low power mult).

LOGS:
Entries in your logs must show band worked at time of contact, time and date, and transmitting power. Copies of all logs showing claimed scores and signed by the operator must be postmarked no later than March 24, 1976 and received by the contest manager not later than April 18, 1976 or they will be disqualified. Please remember to submit separate logs for Phone and CW. Send logs to: YLRL Vice President, Beth Newlin WA7FFG, 826 W. Prince Rd – 06, Tucson AZ 85705.

AWARDS:
A cup will be awarded to the first place YL and OM on both Phone and CW. Second and third place winners in each contest will receive certificates. Certificates will also be awarded to the high score Phone and CW winners of each state, VE call area, and each country. The winner of the Phone contest cup is also eligible to win the CW cup.

Be sure your logs are legible; no logs will be returned.

SOUTH DAKOTA STATE QSO PARTY
Starts: 1400 GMT Sunday, March 14
Ends: 0200 GMT Monday, March 15

The contest is sponsored by the Prairie Dog Amateur Radio Club. No South Dakota to South Dakota contacts will count. Same station may be worked on different bands or modes or in different counties for multipliers.

EXCHANGE:
SD stations give RS(T) and county, all others will send RS(T) and state, province or country.

SCORING:
For SD stations, final score is number of contacts times the number of states, provinces or countries. All other stations, final score is the number of contacts times the number of counties (67 max).

FREQUENCIES:
CW – 70 kHz up from bottom of band; Novice – middle of Novice band; Phone – 1.975, 3.955, 7.230, 14.280, 21.370, 28.510.

AWARDS:
Certificate to highest single and multi-operator entry in each section.

ENTRIES:
Send signed declaration and claimed score to: WBØEVQ, Box 493, Springfield SD 57062, by April 30, 1976.

CQ WORLDWIDE WPX SSB CONTEST
Starts: 0000 GMT Saturday, March 27
Ends: 2400 GMT Sunday, March 28

Only 30 hours of the 48 hour contest period permitted for single operator stations. The 18 hours off may be taken in up to 5 periods during the contest, but must be clearly indicated in the log. Multi-operator stations may operate the entire 48 hours. All bands, 1.8 to 28 MHz may be used but all QSOs must be 2xSSB only.

ENTRY CLASSES:
Single operator, all band or single band; multi-operator (all band only), single or multi-transmitter; multi-operator, multi-transmitter only allowed one signal per band.

EXCHANGE:
RS and 3 digit progressive QSO number starting at 001, use 4 digit number over 1000; multi-transmitter stations use separate numbers for each band.

POINTS:
QSOs with stations on different continent – 3 points on 14 to 28 MHz, 6 points on 7 to 1.8 MHz. Contacts between North American countries (not your own) count 2 points on 14 to 28 MHz, 4 points on 1.8 to 7 MHz. Contacts between stations in the same continent but not in same country count 1 point on 14 to 28 MHz, 2 points on 1.8 to 7 MHz. Contacts between stations in the same country count only for multipliers, not for QSO points.

MULTIPLIER:
The multiplier is the total number of different prefixes worked regardless of band. Each prefix may be counted only once. Each special bicentennial USA prefix worked counts as a multiplier of 2.

SCORING:
Single op, all band and multi-operated stations – total number of QSO points from all bands times the total multiplier. Single op, single band – total number of QSO points from that band times the multiplier. NOTE: A station may be worked once on each band for QSO points, but the prefix multiplier is only counted once.

AWARDS:
Certificates will be awarded in each category in each country, and each call area in US, Canada and Australia. Other special awards and trophies will be awarded as listed in *CQ Magazine*. To be eligible for awards, single oper-

* = described in last issue

ator stations must work a minimum of 12 hours; multi-operator stations must work a minimum of 24 hours.

LOGS:

Show all times in GMT, use a separate sheet for each band. Prefix multipliers should be entered only the first time they are contacted. Logs should be checked for duplicate QSOs and prefix multipliers. It is recommended that you use a prefix check sheet and include it with your entry. Each entry must be accompanied by a summary sheet listing all scoring information, category, and your name and mailing address in block letters. Also, a signed declaration that all contest rules and regulations for amateur radio in your country have been observed should be included. Official logs and summary sheets are available from *CQ Magazine*. Send a large self-addressed envelope with sufficient return postage or IRCs to: CQ WW WPX SSB Contest Committee, 14 Vandeventer Avenue, Port Washington, LI, NY 11050. All entries should be postmarked no later than May 1, 1976 and addressed to the address shown above. The deadlines will be made more flexible in rare isolated areas.

Please check the January issue of CQ Magazine *for complete rules and changes made at the last minute.*

TENNESSEE QSO PARTY
PERIODS:
2100 GMT Saturday,
March 27 to
0500 GMT Sunday,
March 28; 1400 GMT to
2200 GMT Sunday,
March 28

Tennessee stations on Phone, call "CQ TENN QSO PARTY," or on CW call "CQ TN." Test variations to encourage contacts from non-contestants will result in disqualification. Repeater contacts are not allowed. Mobiles compete against mobiles, portables against other portables. Minimum of 5 contacts from each county for mobiles and portables to earn bonus points.

EXCHANGE:

Tennessee stations send signal report and county. Out of state stations will send signal report and state, province or country. Each station may be worked twice on each band, once on CW and once on Phone. Mobile and portable stations may be worked each time in a different county.

SCORING:

Score one point for each Phone QSO and 1.5 points for each CW QSO. Tennessee stations multiply total number of QSO points times the sum of different states, provinces, and Tenn counties – include Tenn as a state also. Portable and mobile stations receive 200 extra bonus points for each county outside their home county they operate from. This bonus is added to their total score after using the multiplier. Out of state stations, multiply the total QSO points by the total number of Tenn counties worked.

FREQUENCIES:

3550, 7050, 14050, 21050, 28050, 3725, 7125, 21125, 28125, 3980, 7280, 14280, 21380, 28580

LOGS:

Logs must show: date/time in GMT, station worked, band, mode, exchange and score. Use separate logs sheets for each band over 25 contacts made on. Submit cross check sheet if you make over 100 contacts. Logs must be legible to avoid disqualification. Mailing deadline is April 25, 1976. Include a self-addressed stamped envelope if eligible for certificates; every entry will receive a summary of the QSO party with a certificate if eligible. Send logs to: Dave Goggio W4OGG, 1419 Favell Dr., Memphis TN 38116.

AWARDS:

Plaques will be awarded to the top score in and outside of Tennessee and to the winning portable and mobile. Certificates will be given to every station sending in a log with 10 contacts or more.

DEHC

Enclosed is some information about Ecuador's new Diploma for Amateurs and SWLs. Please let your readers know about it in your magazine.

Diploma De La Linea Ecuatorial (DEHC). This FB DIPLOMA is available to stns making required contacts with stns in HC-ECUADOR, the land of, and named after the EQUATORIAL LINE. AF, AS, EU, OCE ... 1 QSO. Any Novice ... 1 QSO. N.Am., C.Am ... 2 QSOs. S.Am ... 3 QSOs. Any band, mode. Ok for SWLs. QSOs from 15 Nov 1945 count. To apply send: List of QSOs, 1 dollar U.S. or equivalent, or 8 IRCs to:

DEHC Mgr. R. Dorsch HC5EE
PO Box 253
Cuenca, Ecuador

BARTG SPRING RTTY CONTEST
Starts: 0200 GMT Saturday,
March 27
Ends: 0200 GMT Monday,
March 29

Only 30 hours of the total 48 hour contest period may be operated. The 18 hour rest period can be taken at any time, but off periods may not be less than 3 hours at a time. Times on and off the air must be summarized on the log and score sheets. There will be separate categories for multi-operator and SWLs. Use all amateur bands from 3.5 to 28 MHz. Stations may not be contacted more than once on any one band. In addition to the ARRL country list, each W/K and VE/VO call area will be counted as a separate country.

EXCHANGE:

Time in GMT, must be a full 4 figure group – use of "same" or "same as yours" will not be permitted. RST and message number. Message number must consist of a 3 figure group starting with 001 for the first contact.

POINTS:

All 2-way RTTY contacts with stations within one's own country will count 2 points. All 2-way RTTY contacts with stations outside one's own country will count 10 points. All stations will receive a bonus of 200 points per country worked including their own. NOTE: Any one country may be counted again if worked on another band, but continents are counted only once.

SCORING:

The total score is the sum of (the 2-way exchange points times the number of countries worked) plus (the number of countries worked times the country bonus points times the number of continents).

LOGS & SCORE SHEETS:

Use one log sheet for each band and indicate any rest periods. Logs must contain: date and time in GMT, callsign of station worked, RST report and message number sent, RST report and message number received, and exchange points claimed. All logs must be received by May 31, 1976 to qualify. The judges' decision will be final. Send contest logs to: Ted Double G8CDW, 89 Linden Gardens, Enfield, Middlesex, England EN1 4DX.

AWARDS:

Certificates will be awarded to the leading stations in each class and to the top stations in each continent and each W/K VE/VO call area. The final positions in the Results Table will be valid for entry in the "World Champion of RTTY" Championship.

If any contestant contacts 25 or more different countries (W/K VE/VO call areas do not count as separate countries for award) on 2-way RTTY during this contest, a claim may be made for the QUARTER CENTURY AWARD issued by the British Amateur Radio Teleprinter Group and for which a charge of $2.00 or 8 IRCs is made. Make your claim at the same time as you send in a contest log. Holders of existing QCA Awards will automatically have any new additional countries added to their records.

If any contestant contacts stations on 2-way RTTY with all six continents and the BARTG Contest Manager receives contest logs from the operators in those six continents, a claim may be made for the WAC Award issued by the RTTY Journal. The necessary information will be sent on to the RTTY Journal who will issue the WAC Award free of charge.

RESULTS

RESULTS OF THE 1976 PACC CONTEST, sponsored by VERON of Nederland

This list shows the first place winners in each country/call area where certificates were awarded. An asterisk next to a score indicates a multi-operator entry.

letting off some steam. You could do worse things with your time.

MORE HELP NEEDED

Though we have a staff of 28 working on *73 Magazine*, we need one or two more and we need them badly. Our publishing of new books has been much slower than we've liked because we just don't have enough technical people to work on them. And our testing and work with microcomputers has been very slow since none of us know anywhere near as much as we should about them. We know they are going to be very big before long, but we need help to keep up with them.

If you have a good background in hamming . . . have worked with slow scan, RTTY, DXed a bit, built a lot, maybe written some articles . . . you might be missing a good bet for a place to work. If you have been playing with microcomputers, have built some of the interfaces, done programming in two or three languages, are able to explain to the average ham the difference between an assembler and a compiler, and have some articles to your credit, you could do worse than write to *73*.

73 is by far the most informal of all the hamrags to work for. We don't get as much work done at times, but we have a lot of fun . . . and there just isn't a better place to live in the whole country if you like relatively mild winters and summers, like to ski, camp, hike or things like that. New Hampshire is still a rare state for hamming and the mountains are fantastic for repeaters and UHF work. Peterborough is not far out of Boston, yet it is a country village nestled among the mountains, with three ski areas within a fifteen minute drive.

If you enjoy hamming, we're set up with a superb DX station on 20m, a fair Oscar 7 mode B setup, and all kinds of ham gear coming and going . . . RTTY, SSTV, FM, uP, you name it. The pay is geared to single people, not families.

Write.

HEATH BITES BITTER BULLET

As I understand the situation, Heath has recalled all of the HW-2026 synthesized transceivers. This is a move without precedent in the amateur field, to my memory.

The move could easily cost Heath well over half a million dollars, which is a very big number in the ham field. The rig sold for $289.95 in kit form (see page 100 of the January *73* Heath catalog) and Heath is offering to refund the original payment plus $25 if the kit has been partially assembled and $50 if it has been completed.

The problem was one that came as a surprise. It seems that there are some spurs coming out of the synthesizer which could in some areas of the country cause problems to other services . . . and this is on receive as well as transmit. Since the receiver was tested and okayed under Part 15 for such radiation the problem must be a very low level of spurious radiation. Extensive tests in the Michigan area by Heath amateurs turned up no problems, but difficulties began to arise when the units were put on the air in rf-congested areas such as New York City.

The first reaction, naturally, was to see what modification could be devised to cure the spurs. It turned out to be such a difficult mod due to the microparts involved that the half million dollar decision was made.

Bravo Heath!

In view of this situation, which has cropped up several times . . . I believe it was an amateur FM rig that brought on the FCC demand for all receivers to be put through Part 15 spurious emission tests . . . and with the problems encountered by at least two other synthesized rigs, it might be prudent for manufacturers to get prototypes checked out in a couple of major urban areas before releasing production runs in quantity. If manufacturers have any problem finding volunteers from among the field of waving hands I'll be much surprised.

Adventure

For a time, all the solid state surplusers were featuring returned or defective calculators that you could repair, with the instructions furnished. Some of the offers were absurd; the best I found was from Meshna, who offered an ac desk calculator for ten dollars, and a dc version for eleven. They were eight digit, and basic, without any radicals, reciprocals, factorials or suchlike. Also, they used a liquid crystal display, which intrigued me. An instruction manual and a magazine reprint went with the deal. I ordered the ac model, with the dc as a substitute if it was out of stock. I got the dc version.

Anyone who goes for a deal like this just to save money is a hopeless romantic – or, at least, hopeless. Either you realize all the other benefits, or you are left holding the bag. I suppose that if you really failed to get the calculator working, Meshna would take it back – he's reliable – but eleven dollar junk is expensive, and an eleven dollar basic desk calculator, plus experience, is a bargain.

In due time I got my calculator, obviously brand new, all done up in a plastic bag. I opened it up and studied both the reprint – which was a discussion on repairing calculators, quite general – and the manual, which was an extract of the original, but with some omissions.

After studying this, I did what 90% of surplus buyers do – I got second thoughts and put it away for about three weeks. What was *I* doing with a busted calculator? If the manufacturer gave up, who was I to second-guess him? The fact that I have been troubleshooting all my life, some of it even digital stuff, made no difference. I felt like a fool.

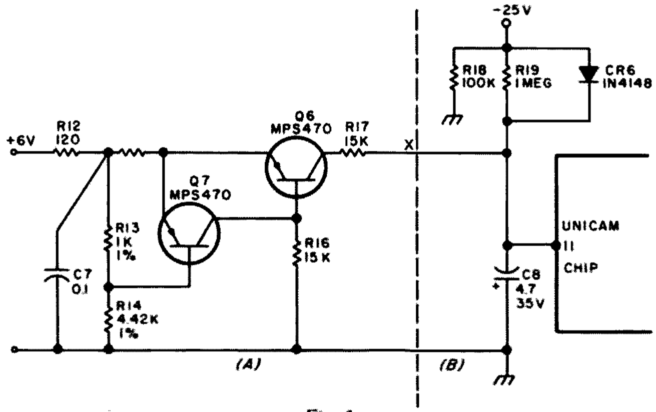

Fig. 1.

But this was clearly unproductive, and I got curious. I had to get a couple of Phillips screwdrivers, too, but I got her open. I saw two halves of a box, with a keyboard and circuit board in the top half, and the plastic light guide, bulb, and battery box in the other. Not much help. I put it together again, installed four D cells, slid the battery cover on, set the box right side up, and hit the "on" latch. The shade popped up, allowing the leaf switch to close, turning on the bulb, and I got light, but that was all. No numbers. Obviously the inverter, which I had read about, wasn't working. I knew you had to work the liquid crystal display on high voltage (comparatively) ac.

The moment of truth. Well, no use stretching it into an hour. I took the case apart again, but this time removed the circuit board and inverted it. My, my! Three big ICs; most of them look like dead cockroaches, but these, exceptionally flat, looked like millipedes. Two rows of legs on each side, an inner and an outer. And the display sticking up out of its connector. If you look closely, you can see the 8s all in a row, in transparent metal.

The rest is the usual peppering of electrolytics and plastic caps and resistors and transistors like canary-bird excrescences with a flat side, all the same size. And, oh yes! – a plastic spool of wire, must be L1.

And there it is. The spool is loose, vibrates a little. I pulled it away from the board, only the outer lead connected. The inner one was broken off. It had to be the inner one – Murphy's Law. All that agonizing and timidity and rationalization and I found the trouble without instruments, just by visual inspection, in 90 seconds! A good carpenter might have taken a minute and a half to find it.

It would not surprise me if each and every unit shipped had exactly the same trouble. In the first place, there is obviously some agreement with the manufacturer to keep the name confidential. It may be part of the deal to insert a defect, to justify the price. The price has to be justified to the buyer also. But the Post Office inspectors come around and maybe Ralph Nader, so instead of something the customer has to find with a triggered oscilloscope, a perfectly good unit with a deliberately broken inductor lead might be the best answer to the whole business. Now all this is my own idea – don't go asking the dealer about it. I could be wrong. But I'm pretty sure you won't get anything through the US mails that you can't fix pretty easily.

The inner conductor of L1? That's simple enough. I took a modeler's knife (they're sharp) and carved away part of the inner bottom edge of the plastic spool, and pulled out an eighth turn or so, and cleaned it. To fit, I needed a longer outer lead, so I unwound and retaped enough. Far less than half a turn all told, and no splices. I cleaned out the solder holes with a round toothpick and mounted the coil by them. Fixed.

Now when I turned it on, I got half a second of all 8s, then 0. The flyback converter was certainly working. The keyboard is like an organ with its long throw and light keys that seem to do nothing, but they do provide tactile feedback and I like them a lot better than those mushy things. The input is algebraic and serial, but nonrepetitive. By accident I found that zero will clear under some conditions, though the C key should be used for this, of course.

Every calculator, even my little Novus 600 which has been roundly – and I think unjustly – criticized, has some particular talent, something it is particularly good at. It didn't take long to find the virtue in this one: It likes decimals. I would never again buy a six-digit calculator, but that is the only limitation I recognize in the Novus. This one has eight digits, which is one hundred times bigger, and I must say I haven't run out of numbers on it yet.

You can do nearly anything on a basic calculator that you can do on the newer fancier ones, which have keys for %, X^2, $\sqrt{X}$, X!, 1/X and such. It just takes longer – you have to work the gimmick as a separate problem and insert the answer as a factor. To take a reciprocal of 1.414 on the Novus, I can't just divide it into 1. It gives me a zero and sneers at me – I haven't left it enough room. So I have to enter 100 000 and divide that by 141, sorting out the decimals mentally. But this box – stick in a 1, divide 1.414 = 0.7072135 no strain. The liquid crystal display is odd – for one thing, it's bland, white, like cigarette smoke in a bottle. It's slow – you can see it go on and off, unlike the LED type. The driving circuit must look like wallpaper; you can't multiplex this type. The display has more leads going to it than you ever saw, like cattails in a swamp. Were I building one, I should never specify a liquid crystal – either LED or flourescent tube. But now I have this one, I like it, and its slowness doesn't bother me. It is by no means a limitation. For variety I may later dye the bulb with modeler's colored lacquer. You can get it in tiny 25¢ bottles.

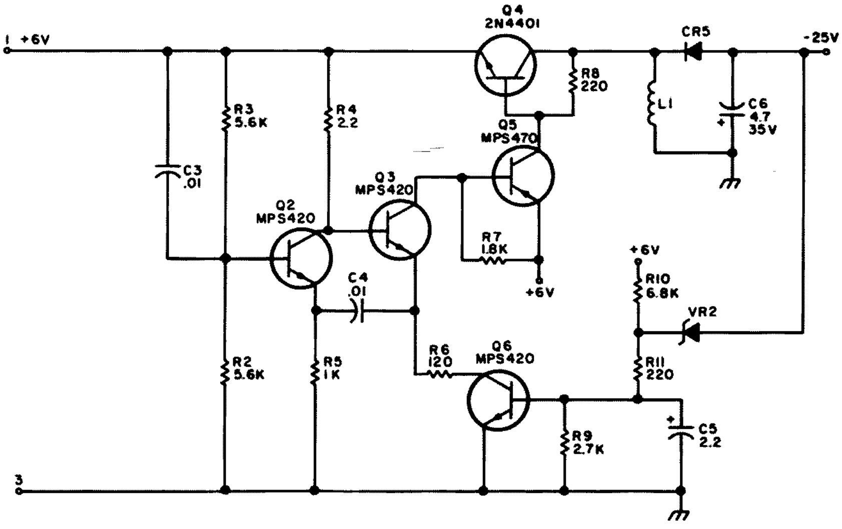

Fig. 2.

Now a "wild" trouble came in. The calculator still worked, but it didn't show "all 8s" when first turned on (see Fig. 1). I lifted off R17 to disable the low voltage cutoff (A) and checked out C8 with my VOM. I got a kick. Next I replaced R19 with another one meg without results.

I looked up the circuit in the manual and like Rumpelstiltskin, in the fairy story, you'd never guess his name. He is called a power-on-initialization circuit! Hot diggity zip!

Anyway, when negative 25 volts is first applied through R19, C8 is discharged and practically a dead short, so all the drop takes place across R19 and no voltage appears at terminal 11 on the CPU chip, which disables it and shows all 8s on the display. When the voltage rises with C8 charge, the 8s vanish and 0 appears, and you are ready to go. But I didn't get my all-8s-blink until I got up to 3.3 megs. But it seems that I had some pretty low voltage cells by that time, and later with good cells, 3.3 megs gave me a fifteen second wait. I went back to 1 meg and get five seconds, very nearly, which suits me fine. It has continued so without trouble.

Reconnected at X, Q7 and Q6 are a Schmitt trigger it says here. Looks like Q7 conducts when its base is above 4.0 volts, and cuts off Q6. Below 4 volts Q6 conducts, loading R19 and giving a permanent all 8s display. There may be a question about having two features on a single indication. But I'd miss the initialization (love that term!) and the low voltage cutoff is kind of fun, too. Now I have reason to believe that the calculator and display end will work on as little as two volts (!) with Fig. 1 disabled. Of course, the bulb won't light either, but the display can be read by light reflected off a white tablecloth. I *know* both will work with 4 V and that's a dead battery. The bulb is a 6 V 150 mA deal, and could be replaced with a 2 V 60 mil one and a 75 Ohm resistor. Less bright, and should serve OK. Could even put a filament rheostat in it – or switch out a couple of 20 Ohm sections. These are, however, sub-desperation measures, and by no means essential. You will get pretty good life as it is.

The long red plus lead from the switch broke off, and I put it back with the rest of the red ones. Even so it was wrong, and left the board permanently connected. When I corrected this, I read the drain to the board and was shocked to see 125 mA. The manual claimed much less than this. Would I now have to get out a CRO and measure pulse widths and frequencies and all that jazz? Not that I couldn't possibly do it; but it would be a pain in the neck for everybody concerned. When I put in new batteries, I measured it again: 50 mils! No, Ohm's Law still holds. The load is constant, relatively; the voltage is regulated and constant, so the power is constant. If input power is also constant, you need a lot more current when you have a lot less voltage; it is as simple as that.

Just in case, let's take a look at Fig. 2. It isn't easy to see any oscillatory circuit here, and I don't guarantee my own ideas. The manual is delightfully vague also, but here

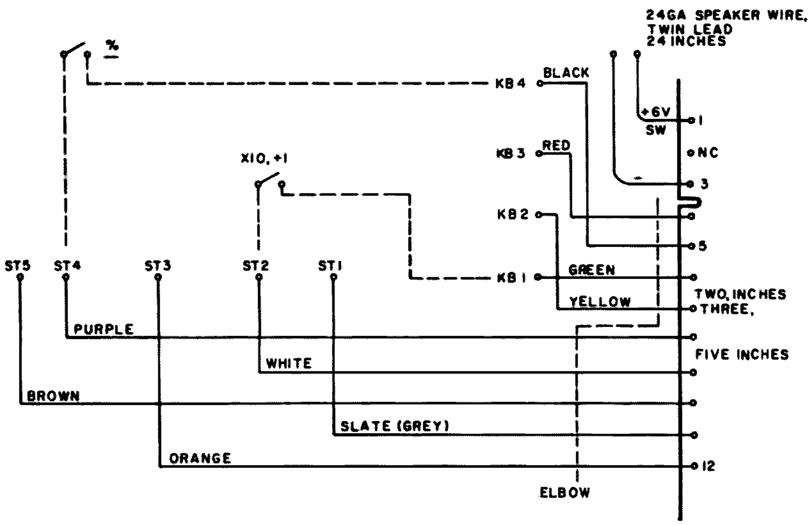

Fig. 3. KB-4 to term 4: 10 inch stranded #20 PVC elbow 3 inches from board, banded at board. ST1-5: 10 inches, 5 inches to elbow, banded to switch near KB-1 for support. Colors shown original.

goes: Initially, plus six volts charges C3. The displacement current increases current in Q2 which lowers voltage through R4 to base of Q3. This reduces current and sends a negative-going pulse through C4 to emitter of Q2. This is the correct phase to aid the signal on the base of Q2, driving it to saturation. Once there nothing changes, so it drops down to cutoff and repeats, but without any help from the – primization? – circuit, C3 R2 R3. Note that there is no Q1. Q1 is the regulator in the ac version. Q5 is the driver, the only female in the bunch. Q6 is the series regulator, looks exactly like the others. When it conducts, it loads up L1 with flux, and when it cuts off – whoops! – high voltage, and pretty efficiently, too. CR5 rectifies, C6 filters.

VR2 breaks down at some specified voltage and lets in a pulse of negative which poisons the positive bias on the base of Q6 more or less. While dc at the base, the rest of the Q6 Q3 Q5 circuit has no frequency limitation. If I missed anything here, write me; that way we all benefit.

Now let us look at Fig. 3. When you first open up the calculator, the little green and red and yellow wires look very pretty. You get the first three openings free, then they begin to break off, spoing! – singly, in thirds, triads, and diminished sevenths. You can learn to hate them cordially in short order. The wires are simply not made for servicing. While not actually "banjo" they are pretty short. I have indicated the colors on the drawing so you will know where to replace them until you can get more wire, but I earnestly recommend something like the #20 stranded PVC and the 24 gauge speaker wire (twinlead) which I used.

You can make a game of it while you are waiting to get the wire – try to determine, from the diagram, and from missing functions, which wires are broken. The keyboard is a scanning type – the ST numbers along the front apron *mean* strobe, while the KB up the right edge (keyboard inverted, of course) are keyboard buses. The number of individual functions available on these keyboards depends on the number of crosspoints. On a four by five layout like this one, there should be twenty, of course. This has, in fact, only seventeen.

An eighteenth is provided for and indicated on the drawing, but there is no crosspoint keyed for it. This is the missing key between ST4 and KB4, and is a % function. I have little use for such a function, but it gripes me to have no access to the capability, so I added a little red push-button next to the "on" shade-latch where there is room for a dozen, maybe less. I have an OAK calculator switch button, but it is a sub-surface mount. I wanted to put it in a blank space between switch and panel, but the present keyswitch assembly is so big there isn't any room. Top mounted, the OAK would look like a lily on a stem and the hell with it. The little red button isn't half bad.

Works, too. Starting with 88888888. one tap gives 888888.88 then 8888.8888 then 88.888888 then 0.8888888 then 0.0088888 then 0.0000888 then 0.0000008 and one more press gives 0. You have to use a firm deliberate pressure, any jitter will give you a double function. The long throw of the regular keys minimizes this. In use, you set up the problem and punch the % instead of the = and you're done.

I've known for some time that some chips have capabilities that are not used in the calculators, to provide for next year's features with a standard chip. This spreads development costs over several years and saves money all around, a desirable conclusion. So I went prospecting on this one. What else was hidden?

KB1 and ST4 crosspoints give an equals function, but we already have that on another key. KB1 and ST2 are something else again. This crosspoint multiplies by ten, then adds one. If you had 87 in the register and operated this crosspoint, you would get 871.

Useless as a tire pump? For normal calculations, yes. But if you equip your calculator for % with an extra keyswitch, leave the leads a bit long so that they will reach this last crosspoint. Then, at need, you can move the leads as necessary. Might turn out to be the best and most useful function the thing has got.

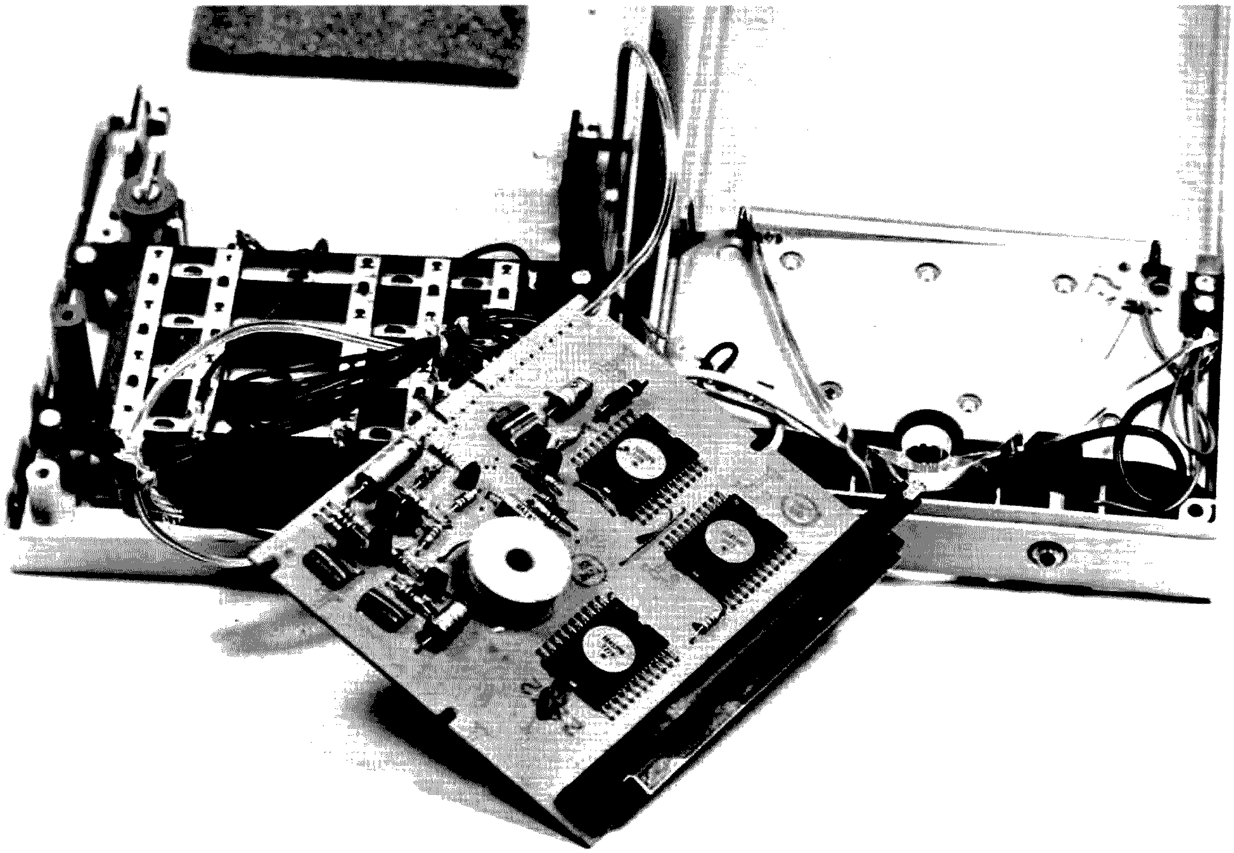
Every family has its wise guy, often a brother-in-law. Tell him about the calculator you fixed. He will sneer, as usual. Show him all the features, let him try it, but make no reference to the little red button. He will discover that it multiplies by ten and then adds one to what is in the register. He will sneer again.

Ask him if he knows how mathematical wizards perform mental feats such as the extraction of any roots of large numbers. What do they use factorials for? If you ask a mathematician what a X 10 + 1 function or constant would be for, they would just look at you. (This is truth, in my experience. Ask them almost *anything* and they'll just look at you. I asked the head programmer for Ma Bell what was meant by "an order of magnitude" and I got the wordless look. They're bright people – it's just when you surprise them with an intelligent mathematical question their brains de-clutch.)

Further, you can claim harassment from the CIA who are after a cypher key – like the Playfair, but completely random and longer than the message, in the modern fashion. This is hidden in the memory of the machine, which was then marketed by mistake, and the X 10 + 1 key will retrieve this when properly used. If you can fix a computer (calculator), you can generate an even gaudier lie than this. Go to it – now is your chance to get even with the – !

To get back to the wiring, two feet of the battery lead is nice. The original lead was always catching on the leaf-switch, and draping over the light guide so that it would appear behind the numbers in a most distracting manner. Now, no trouble at all. It goes on #1 and 3 of the card (between the slots); watch the polarity. No tying was used.

The KB leads were the shortest, banded (tied) together near the board terminals for mutual support. They were not tied to the board. The ST leads were formed into their own separate bunch, joining the KBs only at the edge of the board. Originally it was planned to poke the leads between circuit board and keyswitch, but there simply is not enough clearance. But the board is set back a little, making a front porch of the ST terminal strip. Putting elbows in the bunches



of wires and folding them and dressing them to clear is simple and quick, and that cabling is good for as many times as I want to open the box.

Now that you know what we're talking about, the photograph will explain more of the details. The top and bottom and the removed board were all jammed together to get as much detail as possible in the photograph, but when actually working on the thing, you would have the cabling stretched out, top and bottom halves well spaced with the board on edge, or even flat, between them. It sure beats the original wiring.

The light guide is interesting to the optical students. You get such a perfect field that you don't even notice it, but try to get projection like that with lenses you can afford! The plastic is Lucite, cast, with locating bosses, and a two-side-sticky tape mounting that has given me no trouble so far. The shape is near-parabolic, with the light bulb near one focus. You get total refraction along the curved edges, and straight out the straight far side. Cheap, effective, and plenty hard to duplicate by any other means. The bulb socket is held on a boss by a spring wire clamp that has one leg up, one down. You can grab the up leg in "flats" (pliers, long-nose) and adjust it readily.

R19 is that big ¼ Watt 1 meg jobbie on the board. The original 1/8 or whatever went haywire and changed its resistance, as they sometimes do. You never know if they will go up or down, and this one went down. All you can get is one quarters, so I bent the leads under the body to the correct spacing. It fit nicely.

Now is the time to say something nice about the circuit board. It is opaque, like wallboard, and thick. The thing is one-sided, and the conductors swirl all around to avoid crossovers. It is lacquered green, and the swirling patterns look like big thumbprints in green paint. The whole thing looks a bit on the crude side, especially after working on fibreglass high frequency types.

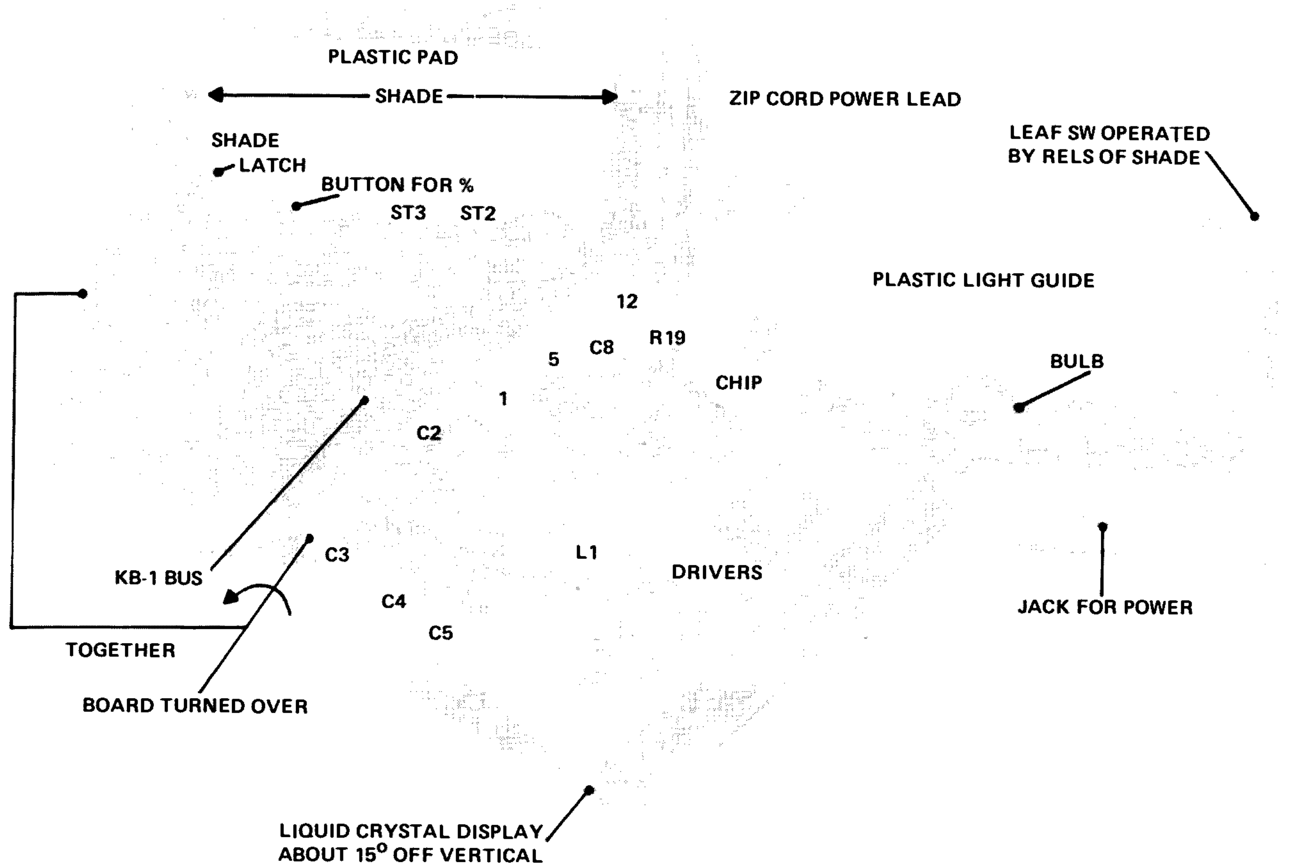
But whoever specified this board knew what he was about. There's copper there, and it is cemented on to stay, and the lacquer helps prevent solder bridges. To work on a board like that is to appreciate it. Remember that I cleaned and replaced all the damned little pretty-colored wires many times, I had the R17 up and down like a pump handle, and I replaced an eighth Watt resistor with a quarter Watt one — no trouble at all. Nothing blistered, nothing came loose. True, I have worked on printed circuits before, I was using a small iron, I was using "microwave soldering technique" and I never let myself forget that it *was* a circuit board I was working on. Nevertheless, I didn't baby it, and if you can be trusted with any board, or indeed, with any modern kit, you'll have fun with this one. It's good stuff.

The case — neat but not gaudy. Green-top keys, egg-shell white case. I don't think it is any hi-impact plastic. I think it is the good old Styrene plastic, easy to break, easy to burn, easy to melt, and easy to carve. Drills easy, too. The chaff, or chad, or sawdust, or whatever becomes highly charged and wants to get on the screen where you don't want it. Try the sticky side of Scotch tape (C) to swab it up. Get it all if you can.

The thing is held together with self-tapping screws. Don't lose any, because these are long and skinny and you may not find the sizes. They seem to be double-threaded — if they don't screw in well, back out a half turn and try again. If still not, swap with the other of the same pair. Makes a surprising difference.

There is no number or logo on the calculator. The book says ACCUMATIC E630 and gives a parts list, but who can you buy parts from?

Following some tenuous indications, I called Rapid Data Systems, Toronto Office, 129 Carlingview Drive, Rexdale, Ontario. Their number is 416-678-1000 and they referred me to an agency in the States: Calculator Service, 29245 Stephenson High-



way, Madison Heights, Michigan. Their number is 313-399-4300. They were unable to identify the model, thinking it must be a prototype (come *on*, a production run of *prototypes?*). I asked about the Liquid Crystal Display RA-90009 and he gave a corresponding number #1930801-1 which was priced in single units at $15. So much for the economics.

Meshna advertised his two types of calculators in several flyers, a couple of issues of magazines and at least one catalog. He no longer advertises them, and for a good reason — his stock is running low. A lot of guys will buy them and put them away for a time, as I did, and some will continue to order from old catalogs or ads, so sales will slow down but not cease.

On November 14th, Meshna told me he had 200 units in stock. I don't know how many he has at this writing. If you want one, order as soon as you read this. There are other data I'd like to include in this essay, but there simply isn't time to get it up — you have all you really need, anyway, so here goes for the Post Office. Happy initialization! ■

---

amsat

Thought you might be interested in hearing about my recent Oscar 6 contacts with ZK1DX. This took a couple of months to set up and accomplish. To date we have made 3 contacts via Oscar 6; they were direct with no Tropo assist. If you study the distance involved you will find our range overlay to be approx. 300 mi. max. Our communications "window" is 30-45 seconds max. Rarotonga is located on the 20th parallel south of the equator; this all makes for a very interesting 2 way contact.

Wyn ZK1DX uses 80 W out and an 11 element yagi. Equipment here is Echo II and amp 80 W out, to a pair of stacked 9 element yagis with az-el control at 50. Receiver is a Kenwood R599 and Westcom Noise blanker and preamp and 3 element yagi.

I also managed to get a good tape of our last SSB QSO.

Enjoy your column.

AMATEURS ACCESS COMPUTER VIA SATELLITE

On October 9, 1975, two radio amateurs made the first claimed remote access of a computer not only by means of a two way radio link, but also through a communications relay satellite.

This milestone was initiated by W. Franklin Mitchell Jr. operator of amateur radio station WB4BWK in Due West, South Carolina, when he transmitted an "execute program" command to a Mod 8 microcomputer located at amateur radio station VE2BYG/3 operated by Randall S. Smith in Barrie, Ontario, Canada. Randy has since changed his callsign and is now known as VE3SAT.

Randy's microcomputer received the command relayed by means of the AMSAT-OSCAR 7 satellite and executed the stored program, transmitting a preset message from VE2BYG/3 to WB4BWK. The data was transmitted in ASCII code at a rate of 110 Baud. The Federal Communications Commission has granted a waiver to radio amateurs interested in computers and radio teletype allowing them to transmit ASCII coded information through the satellite.

Both Randy Smith and Frank Mitchell are members of AMSAT, a nonprofit worldwide organization of radio amateurs based in the Washington DC area.

Tunable FM Receiver Strips

Almost all surplus land mobile service receiver strips which find their way into the amateur service are dual conversion crystal controlled systems. The primary frequency selection used in the first conversion is a crystal bank which usually costs more than the receiver. These crystals are required to perform at close tolerances which previously were of little concern to the amateur unless he worked at band edges or nets. In order to have use of all available frequencies, the operator must either pay the price of many crystals or install fairly expensive frequency synthesizers. There is another way. Some thought and experimentation at W1SNN produced additional frequencies as well as a snooping oscillator which allows the receiver to be tunable over a very narrow range and keep the stability and close tolerance frequency control. Let's take a look at the block diagram, Fig. 1. The diagram indicates the approximate configuration of two well known receiver types, a Motorola Sensicon and the General Electric Progress Line strip.

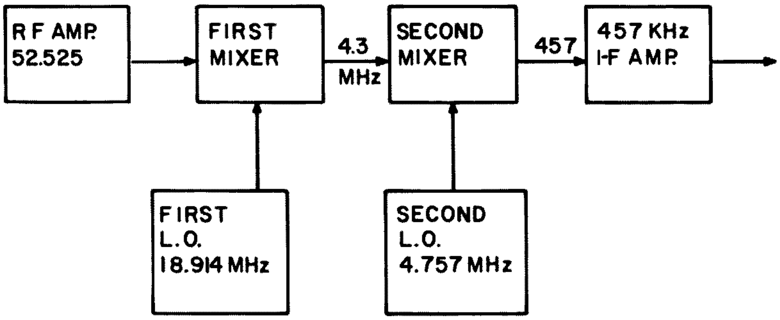

Fig. 1.

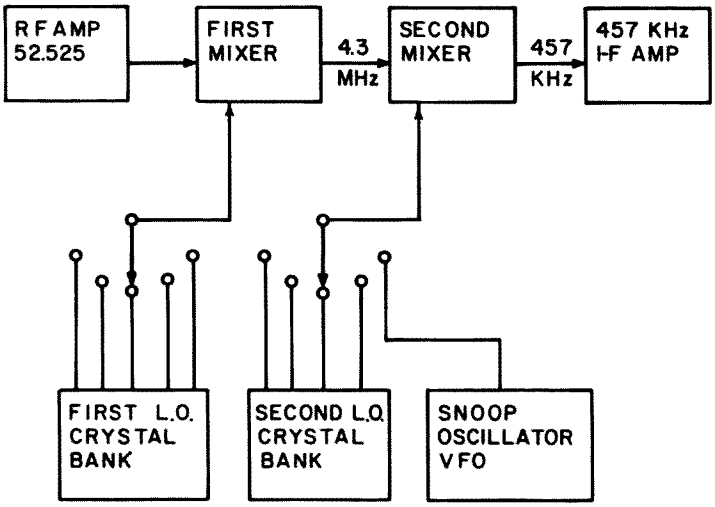

Fig. 2.

The input and cutput circuits of the rf amplifier and the first mixer have double tuned critically coupled circuitry which reduces the effects of nearby transmitter desensitization among other things. Similar circuitry is used as the output of the first mixer and is carried even further to the input and output of the second converter. For this reason these receivers have a limited range of acceptance for which they can be used without retuning. This is about ±50 kHz. By stagger tuning this can be extended without the danger of desensitization. If the station is far enough away from other transmitters, this is, of course, not too serious a problem.

The reason I went into such detail in the above paragraph is because herein lies the method of adding additional frequency control, at surplus crystal prices, and of adding the snoop oscillator. The quickest way you can move around your existing crystal control frequencies is to change the operating frequency of the second local oscillator crystal. But before we change anything, let's take a careful look at how the local oscillators and i-f frequencies work to produce an operating frequency of 52.525 MHz. A Motorola Sensicon Receiver strip will be used.

According to the manufacturer, the first conversion crystal frequency should be calculated thus:

$$f_o = \frac{f_c + 4.3}{3}$$

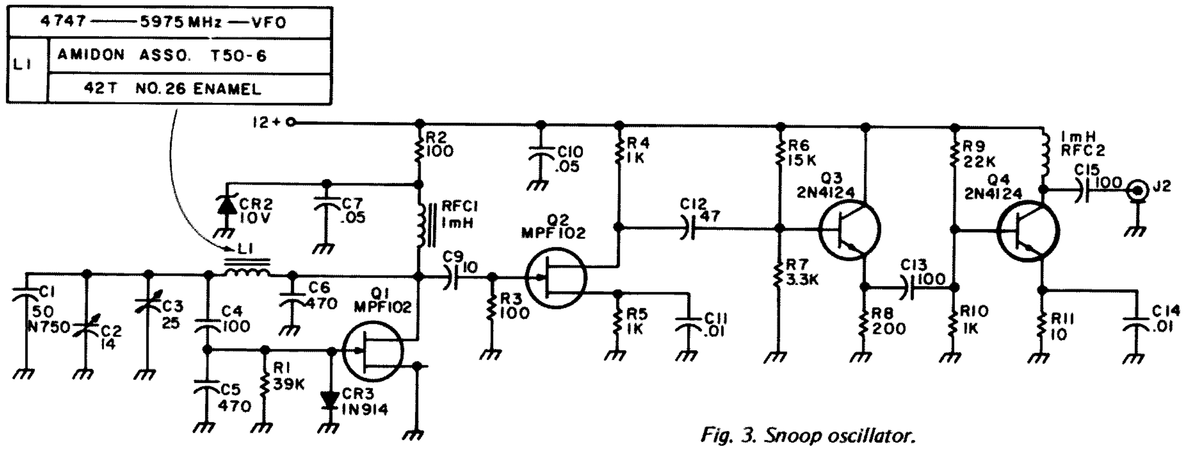

Fig. 3. Snoop oscillator.

where:
f_o = the operating frequency
f_c = crystal frequency
4.3 = second conversion i-f
Therefore, for a crystal to operate on the receiver on 52.525 MHz . . .

$$\frac{52.525 + 4.3}{3} = 18.9416 \text{ MHz}$$

Now to get the second conversion crystal to an i-f frequency of 457 kHz, a 4757 kHz crystal is used in the second local oscillator and is calculated thus:

$$f_{2n} \text{ conversion} = f_{2c} + f_{2i\text{-}f} \text{ or } 4.3 + 457 = 4757 \text{ kHz}$$

Now let us dip into our sacred junk box, and lo and behold, there is that crystal you have saved from a chunk of surplus. It has a frequency of 18.930 marked on the can and it is a fundamental crystal with the right pin spacing. So let's stick these numbers into the first equation and see where we end up. It comes out twenty kHz low, you say. Well now, if you add that 20 kHz to the second LO crystal and make it 4797 kHz, the second formula will show the correct i-f difference of 475 kHz and the first formula will show that we are on 52.525 MHz. So now you say, "Well, I have to buy the second crystal." Right, you do, but look at the surplus lists and see the nice low price.

One word of caution: Remember that the crystals used must be chosen to look into a 32 pF load and that there are many that use a lower capacitance load and the frequency will come out somewhat different than calculated. This can, in most cases, be taken care of with a frequency trimming capacitor.

All of the foregoing may sound like some kind of "hocus pocus" but be assured it is not. The manufacturers of these two strips and many others describe the same techniques for "exact frequency tuning," and although it is not as extensive a frequency excursion, it is done in the same way.

Now observe the second block diagram, Fig. 2. The crystal banks shown are substituted with a logic oscillator[1] allowing the operator to switch at will to whatever frequency he chooses to generate. Also there is a vfo unit shown which can be switched into the second crystal oscillator grid. Now you have a snoop oscillator which allows you to tune around the very narrow bandpass and listen to what is going on in between the channels.

The crystal oscillators shown are the same as the original logic oscillator. The changes are to improve the original circuit which used TTL logic blocks; the new circuit uses CMOS logic. The noise immunity of these units allows a less stringent power supply source regulation and in our case allows the use of a simple zener diode regulator coupled to the main supply voltage through appropriate voltage dividing resistors.

Crystals used in this oscillator must be fundamental types. The circuit has been used with crystals up to 20 MHz and I am sure if I had higher fundamental rocks it might go to 25 MHz before the logic block would start to react sort of funny. The circuit shown is in use at W1SNN for the six meter FM band. On two meters the addition of a frequency multiplier will provide the correct harmonic before it is fed into the crystal jack.

The circuit of the vfo was taken from the article in November, 1973, *Ham Radio.*[2] It is the very stable Vacker Oscillator which was used as a twenty meter vfo. The frequency has been changed to suit the Motorola and General Electric Progress line receiver strips. It is shown as it was modified for this application. It would be a good idea to review the article described and use the construction practices used by that author. This unit has been mounted in a nice cabinet and the output fed through a six foot coaxial cable to the oscillator jacks. The output of the snoop oscillator is brought out through a coax jack as indicated. A length of coax up to about eight feet long can be used and therefore only the new crystal bank and the snoop oscillator need be stationed at the operating position.

The second local oscillators for either the Sensicon or the Progress Line strips are fed into the grid side of the crystal socket or directly to the grid of V5 pin 6 on the Motorola or to pin 7 of V319 of the General Electric receivers. Although no modification

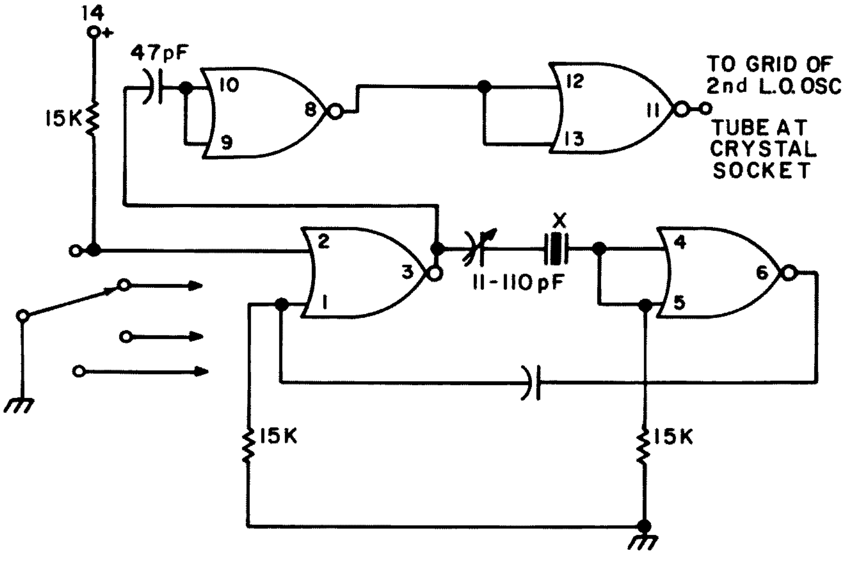

Fig. 4. CMOS oscillator.

of either receiver is required for this adaptation, it would be wise to have the receivers working before trying these stunts. I modified a crystal can head by unsoldering the can, removing the contents, then drilling a hole in the can top to allow passage of the coax through, then soldering on the coax leads to the pins in the header. Reassemble the can to the header and now you have a plug which will fit directly in the crystal socket. Make sure that ground goes to ground and so forth . . . or it won't work.

The same procedure as has been described for six meter receivers can be applied to any of the high band strips which are first converted to two meters. In our case we used another Sensicon Strip PA 9033, and after it was set up and working the vfo – crystal bank was plugged in and away we went. In the above mentioned receiver, the second conversion mixer is a pentagrid converter which also serves as the second LO. To use the adaptations described, the receiver should have this minor addition or my name will be changed by many of you. It is done thus: Locate the second mixer tube, a 6BE6 designated V6 in the circuit diagrams found in the instruction books, disconnect the wire which runs from the crystal socket X-19 to pin 6 of V6, and ground this wire. If this procedure is not followed, plugging in the vfo as described in the prior paragraphs will ground pin 6 and part of the B+ line and create my new handle.

It is hoped that these ideas will be of some use to other amateurs who enjoy using what they have and modifying circuits to achieve an inexpensive adjunct to their stations. ■

Surplus Circuit Boards— A Gold Mine of Parts

Surplus circuit boards are currently available which contain many parts of value to "home builders" and experimenters. Many builders pass these by for two reasons: One is that the parts are too difficult to remove, and the other is that they probably don't realize what actually is available. Several articles have been written on various methods for removal of these parts, from unsoldering them using a "solder sipper" and special tips (which usually damages the component), to submerging the components in a tray of water and unsoldering (very unsatisfactory), to fracturing the board from around the part (this ruins the board). Offered here is a method of recovering parts without damage, and with a minimum of effort, and which leaves the board in usable condition.

To remove diodes and transistors, closely examine the board to determine how the leads are bent over. Carefully force a small screwdriver under the lead through the solder blob (I use a jeweler's screwdriver), and "dig" out the lead clear of the solder or break the lead and solder blob free from the surface of the board. (See Fig. 1.) Then, using a pair of long nose pliers, carefully pinch the solder blob (if it was lifted from the board) to crack it. (See Fig. 2.) In either case, the next step is important. For transistors, carefully pry the transistor off of the circuit board with a small screwdriver, exerting even pressure at several places around the case where it contacts the board. (See Fig. 3.) After removal, excess solder can be crushed off the lead with the long nose pliers.

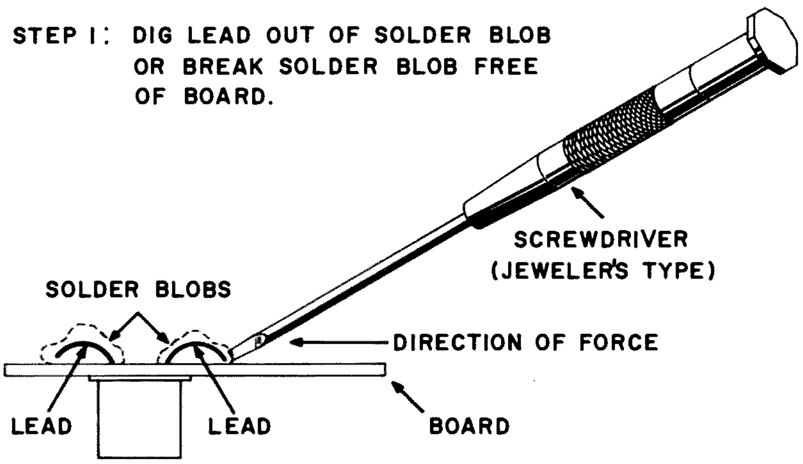

Fig. 1.

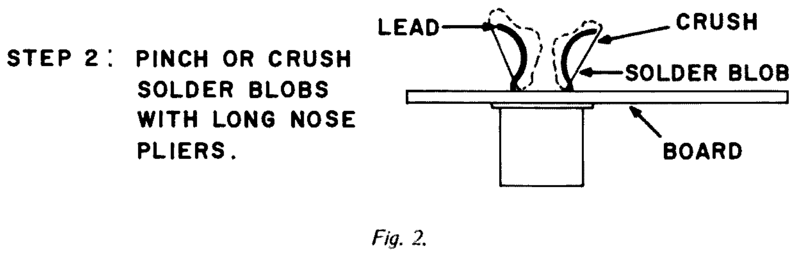

Fig. 2.

To remove diodes, after processing as above, carefully lift the lead (on the component side of the board) with small pliers and gently "tease" (pull) it free or slip a screwdriver between the lead and the board and gently lift it off.

Resistors and other components which can be slightly heated may be removed in a similar manner, but the solder blob should first be removed by heating with a soldering iron. While the blob is soft, gently strike the edge of the board on a hard surface to remove the molten solder; the lead can then be pried up as described above.

Power transistors pose a special problem, but by using the screwdriver method, the (usually large) solder blob can be flaked away and reduced in size so the component can be pried off without damage. If on your first attempt you break a lead and ruin a transistor or two, don't be discouraged — soon you will learn just the right amount of pressure to exert.

Extra caution is required when prying the lead up from the solder blob. Number one: *Point the screwdriver in such a manner that if it slips it won't gouge your hand or leg or other body parts.* Second: Do not use too much pressure or else you may shear the lead. Third: Take your time.

Transformers and other items mounted by rigid leads may be removed by first "digging" away as much of the solder as practical, then prying the component off with a screwdriver while heating the solder blob with a soldering iron (do not overheat). After the components are removed, the board may be further processed by removing the printed circuitry with a coarse rasp and finishing off with sandpaper to remove any remaining copper. An X-acto knife may be used, with caution, to remove solder and copper from the board.

The following components have been successfully removed from the popular 8 for $1.00 boards being offered by "Radio Shack" and other parts houses:

Transistors: Both germanium and silicon, PNP and NPN types, including "power types," usable up to 60 MHz (by actual test). Many may go much higher.

Diodes: Both germanium and silicon, glass and plastic types, including zeners.

Resistors: 1/4 and 1/8 Watt 5% tolerance, conventional types and many precision 1% tolerance types, various ranges.

Capacitors: Silver mica, and tubular ceramic types, various ranges.

Inductors: Molded plastic types, all marked with inductance rating in uH.

Electrolytic Capacitors: Tantalum types, 5 to 200 uF in voltage range of 10 to 50 volts.

Transformers: Molded plastic case, various ratings, marked with diagram.

Relays: Dry reed types, NO and NC types, 3000 to 7000 Ohms dc resistance, which close or open at 5 through 10 mA.

Crystals: 1000 kHz precision units.

Trimpots: Precision potentiometers, screwdriver adjust.

Heat sinks: Finned types, aluminum.

Chokes: Molded plastic, iron or ferrite core types, all marked with inductance rating.

Rectifiers: Marked with manufacturer's number; used and tested up to 110 V RMS.

Others: Several unidentified components which appear to be "Darlington" types of transistors and some possible high current diodes (zeners?).

Circuit Boards: Various compositions, laminated phenolic, fiberglass, etc.

All of the above were removed in good condition and were usable in home construction projects. Since using this method, I have not had to buy blank circuit boards, resistors, electrolytic capacitors, transistors, diodes, etc., for several months.

When selecting these boards (if you make a "hand" selection), try to select those with the parts you need most, and watch for those where transistors are mounted away from the board by small teflon or nylon pads. These give longer lead lengths. Please test all components with a transistor tester or ohmmeter before using, for some may be bad, due to the fact the circuit board was "discarded." To date, however, I have not yet encountered a bad component. In most cases the lead lengths are sufficient to allow full usage of all components; a clamp-on type heat sink may be required, when remounting some diodes and transistors.

This method is also useful when repairing small radios, tape recorders, and circuit boards in general when it is necessary to replace a component. ■

The Perils and Pleasures of Surplus Shopping

Everyone likes a bargain, especially with today's prices soaring to new heights. Ham radio can be an expensive hobby even to the ham who home brews his own equipment. A visit to your local electronics supermarket will confirm this, just as a visit to the other kind of supermarket shows where most of the paycheck goes.

One's thoughts naturally turn to getting things for less money. In many cities, bakeries have thrift outlets where out-dated baked goods are sold at substantial savings. Of course, it pays to peer through the wrappers for any trace of mold just in case the baker cut the final sale date a little too close.

The electronics industry has its own versions of the bakery outlets, the traditional electronic surplus outlets which can be found near most major American cities. You can make some excellent buys there, but you can also get stuck with the electronic equivalent of moldy bread if you're not careful.

Let's review a few of the perils and pleasures of buying surplus electronics. Although every transaction is unique, a few general types of situation emerge repeatedly. This list, by no means exhaustive, applies in general to both mail order and eyeball-to-eyeball purchases:

The Inadvertent Burn
The Deliberate Burn
The Speculative Plunge
The White Elephant
The Outright Disaster
The Home-wrecker
The Unpleasant Surprise
The Submerged Surprise
The Pleasant Surprise

The Inadvertent Burn

A post-purchase discovery that what you see is not necessarily what you get. This is an especially common occurrence when a part's function isn't immediately obvious. Back in the old days, big chunks of filament rolling around inside a tube's envelope were a dead giveaway. But have you ever heard a 709 op amp rattle? (A friend of mine has, but that's another story.)

Your friendly neighborhood surplus dealer will often correct an Inadvertent Burn, especially if you ask him politely. Remember, it may not be his fault. But if your purchase was a one-of-a-kind, last-one-on-the-shelf item, you'll have to renegotiate the transaction and settle for something you can't really use. Cash refunds are possible – it doesn't hurt to ask.

The Deliberate Burn

If your surplus dealer does this to you, drop him. Fast. Even if his shop is loaded with cheap, mouth-watering goodies. You have enough hassles of this variety in your life as it is, what with unscrupulous used car salesmen and government officials. Write to your local consumer protection agency and describe what happened; they may be able to help you recover your money. Your letter may be the capstone to a case they have in preparation, which could result in lots of people recovering their money.

The Speculative Plunge

It's not always the dealer's fault. You can be hoisted with your own petard, as the old saying goes. For instance, that bag of 0.1 Ohm wirewound resistors is a real bargain, especially if you decide to build that power supply which uses a 0.1 Ohm current sensing resistor. But do you *really* need 221 of them? Still . . .it's only a buck . . .

The White Elephant

A variant on the Speculative Plunge which involves a piece of equipment rather than a component.

I once bought an elderly tube-type frequency counter from a leasing company which was cleaning out its warehouse. At $25.00 the counter seemed to be an excellent buy as it was in working condition and bore few of the scars usually acquired by leased equipment. Surplus ads in various magazines were listing the counter at $150.00, and my thought was, "Wow! I can run the counter for a year, sell it to someone for $50.00, and make some money."

Last month, I took the counter to a ham auction and watched in dismay as a bored bidder took it away – no, stole it! – for $4.00! Here's what went wrong: First, there were no surplus dealers interested in it at *any* price. One dealer I attempted to sell it to wouldn't take it because he had ten more in his warehouse.

"Sure, my catalog price is $100.00, and if I ever find just *one* customer at that price, I'll break even. What? You want I should pay you $50.00 for yours? Gettoutaheah, kid!"

Secondly, the counter was obsolete. Inside that pristine grey case lived at least 36

hungry little tubes and a cooling fan which could have doubled as propeller for a B-29. And at 300 Watts or so, it *needed* that fan. Even worse, the counter would count only to 100 kHz – it was designed that way. If you goosed the input signal up a lot, it might count to 120 kHz, but only if it felt happy that day. It was fine for audio work, but most counter users need some rf capability.

The moral to this story is clear: Make sure that whatever you buy has long-term value to *you* and forget about making a profit unless you're prepared to learn by trial and possibly expensive error. Leave the speculation to the pros and your friend down the block who has a rich and generous uncle. A footnote: A friend of mine just called with the news that we (he stressed the *we* part) have a chance to buy a whole trailerload of World War II radar equipment for only $500.00 . . . we're going to look at it this afternoon . . .

The Outright Disaster

I once purchased a surplus ZM-11/U RLC bridge for only $5.00 thinking that I was getting a bargain. The surplus dealer obligingly let me apply power to the unit and we both watched the magic-eye indicator tube warm up to a healthy looking green glow.

The dealer scrounged around behind the counter and came up with a precision resistor. I connected the resistor to the terminals, switched the function selector to "Ohms," and adjusted the main dial for balance. Lo and behold, the dial and resistor values agreed! "Fine – I'll take it," I said, and went home happily.

Later that evening, I located my standard capacitor and confidently hooked it to the bridge's terminals. I selected the appropriate function, set the test voltage and confidently twisted the balance dial. Nothing happened.

I tried another capacitor, then another, and then some inductors. Still nothing. Frantically, I grabbed a resistor at random from the bench. Again, nothing. By now, I was aggravated. I located another resistor in the same range as the dealer's test resistor and sure enough, it worked.

I unplugged the bridge and reached for a screwdriver. Five minutes later, I was staring at a surplus hound's nightmare. Some misguided individual had attempted to dismantle the bridge (for service, perhaps?) by snipping the many wires which run from deck to deck in this compact instrument. Just for variety, he had thrown in a few solder splashes and odd pieces of hardware. Several freshly-cooked resistors stood out like sore thumbs. I wanted to throw up.

Anyhow, if you should happen to get an Outright Disaster, cheer up. You've plenty of company out there.

The Home-wrecker

This type of surplus purchase is a possible consequence of buying an unrecognized White Elephant. A variation is the bargain-priced, completely useful goody which just happens to be a bit too ugly or dirty to win the acceptance of one's mate or parent.

Once in my youth, I proudly dragged home a pair of vintage BC-375 tuning units in their original packing. I had done well: In a three-cornered trade involving an old Stromberg-Carlson console radio, a half dozen tired 807s, and several hundred baseball cards which included my prized Ted Williams card, I had emerged clearly on top. My friends thought so too, including the former owner of the tuning units who had worried about unloading them before the dampness in his basement caused any damage. If it had, he assured me, we could reverse the trade.

I balanced the boxed-up tuning units on the handle-bars of my battered Schwinn and walked the bike all four blocks home. The rays of the summer sun beat down on me, the bicycle and the tuning units. I began to notice that the boxes smelled slightly of mildew, but thought nothing of it.

I reached home, carried the cardboard boxes downstairs into my basement workshop and proceeded to joyously unpack the tuning units. In minutes, the basement floor was littered with packing material and the tuning units were on the bench. The smell of mildew was quite a bit stronger now as it mingled with the familiar "surplusy" odor of the fungus-proofed tuning units.

By then, it was time to do my paper route and I left. I returned two hours later to find my precious tuning units and all the packing material exposed to the elements in the back yard.

My mother, who is a painstaking housekeeper, was very angry. "Keep that horrible smelly stuff out of the basement! Don't you *dare* bring it into this house until it's had a chance to air out!"

I tried vainly to explain that, if I kept the tuning units outdoors, they would corrode, but she didn't budge. Finally, we compromised on a quarantine period where the tuning units would be allowed to decontaminate in the garage. But ever after that, she insisted on sniffing suspiciously whenever I brought anything electronic into the house. That was the first summer I considered running away and joining the circus.

The Unpleasant Surprise

Every surplus buyer has at least one of these in his or her career. The Unpleasant Surprise may take on many forms, such as discovering that those surplus filter capacitors which you carefully installed in your painstakingly constructed power supply mysteriously short-circuited ten minutes after power-up.

About all that's left is to stare glumly at the smoking ruin and comment at length on the morals, personal habits and ancestry of the capacitors and perhaps the surplus dealer.

Another variation on the Unpleasant Surprise is the Submerged Surprise. Of course, by the time you buy the equipment, most of the water has evaporated. Things look fine, you think, and you plug the receiver (or whatever) into the power socket. Everything works fine . . . for a year, a month, a day or an hour, depending upon how far the moisture-induced corrosion has to go to eat its way through one of the many fine wires in an i-f or power transformer.

Especially insidious is the Salt Water Submerged Surprise. All those dissolved salts in the sea water really up the ante in those games of chemical strip-poker going on in the dunked equipment. Even a prolonged fresh water rinse seldom helps. To avoid those rare cases where an unscrupulous dealer attempts to combine a Submerged Surprise with a Deliberate Burn, look for dried deposits on hard-to-reach surfaces between components. Corrosion on solder joints is another tell-tale sign.

The Pleasant Surprise

The penultimate goal of the surplus buyer. Everyone is pleased when things go his or her way. It's a natural part of the human emotional makeup. But there's a special kind of excitement known only on rare occasions which transcends everyday excitement.

Generally, it's associated with a "first"; for a beginning hunter, it's called buck fever. For a ham, it's that first QSO as a Novice. For a dyed-in-the-wool surplus buyer, it's called the Pleasant Surprise.

Last summer, my wife and I visited one of southern New Hampshire's famous flea markets. We arrived around three o'clock, which is rather late in the day to visit a flea market. Successful dealers have already sold everything, and unsuccessful dealers have begun to pack the chipped china, outgrown clothes, wooden coathangers and various forms of hideous bric-a-brac for the trip home.

As we browsed past the half-empty dealers' stalls, my wife called my attention to a wooden box perched precariously at an angle on the ground next to a still-occupied stall. "That box is full of electronic parts – maybe it's something you'd find useful."

"Thanks," I said and edged over toward the stall for a closer look. It was occupied by a man in his early twenties and an assortment of random junk which I estimated could easily load the battered '65 Chevy parked behind the stall clear to the scuppers.

I ignored the mismatched crockery and soiled paperbacks and concentrated on the contents of the box. About all that was visible consisted of some precision resistors packed in plastic bags, some manila envelopes and a double handful of mixed capacitors and garden-variety stuff. A hand-drawn paper sign read: $10.00 (which was crossed out); $5.00 (which was also crossed out); and finally, Make Me An Offer.

"Can I help you?" inquired the stall's attendant.

"Hi. Yes, I was interested in this box of parts. Would you consider an offer of two bucks?" I inquired.

The man hesitated. "Yeah . . . okay. I'm getting out of electronics and I don't want to cart the stuff home. But I do want the wooden box." With that, he produced a cardboard box and began transferring the parts.

After he finished, I thanked him, handed him the money and picked up the box. I carried the box to the car, locked it in the trunk and hurried back to rejoin my wife. We toured the rest of the flea market and found nothing else of interest.

When we returned home, I carried the box downstairs and spread the contents on the workbench. Surprise! One little brown envelope contained a dozen brand-new Hewlett-Packard hot-carrier diodes. Surprise! A slightly larger brown envelope was stuffed with expensive-looking CK-05 ceramic capacitors. Surprise! A grapefruit-sized bag yielded hundreds of 1N914 diodes; none had leads longer than an inch, but that's enough for printed-circuit work. Surprise! Another brown envelope held an assortment of tubular glass trimmer capacitors, all unsullied by solder or screwdriver.

It went on like that for about an hour. New and used parts of every description fell out of the envelopes. My $2.00 investment had turned into a king's ransom, a home brewer's delight.

Those are but a few of the things that can happen to you when you buy surplus stuff. The list could go on forever, especially when you consider the combinations. And remember, one man's White Elephant is another man's Pleasant Surprise, so keep your eyes open for trading possibilities. In these economically troubled times, a junk box well stuffed with surplus goodies can make the difference between a home brewed project and nothing at all, especially if you're out of work. Remember the motto of the Yankee Packrat: Don't Throw *Anything* Away! ■

Noblesville IN 46060

Space Age Junque

The guy that re-named junk, junque, must have either been trying to be funny, or realized early that one man's old is another man's gold! With thirteen plus years in electronics for fun (hobby-amateur radio) and profit (job-consumer electronics), I am just realizing "junk box" in ham magazines has long been misspelled. It takes most hams the first ten years to accumulate a good "junque box." The "junque box" route to better equipment can mean a complete item of surplus as easily as the bits and pieces. I purchased my first BC-348 for use as a tunable i-f for a tube type converter on 6 meters. I liked it so well (even though I have a TR-6 on 6 meters now), that I guess you could say I got hooked on them. The station and "junque box" now consists of five of them in various configurations.

I give you all this background because over these past twelve years I have collected every article on the breed I could lay my hands on. The BC series 224, 312, 342 and 348 are all close relatives, so this article will apply to them as well. It is the intent of this article to show how to put together the beginnings of a top quality VHF station an item at a time, by spending the dollars you have in the best places. While this article falls under the construction type, it is really more of a job of simple reconstruction.

We (Echo Amateur Radio Group) started our EME facility by compiling a list of already published articles, as covered by my article on EME, *73 Magazine*, Nov. 72, p 271. This article covers one of many modifications made to a BC-348 to adapt it for use as the primary receiver in our EME installation. If you can save money on the receiver, transmitter, or both, without sacrificing anything in quality, it will allow you to put it where it will do much more good. We, for instance, will be running 16 eleven element CushCraft antennas. Do you realize how little transmitter power is then required for use with Oscar? Not to mention what the huge capture area does for receiving gain at a point where tube or transistor noise doesn't kill you.

First things first, so for your "stew" first you must catch your "rabbit!" If you don't already own one, you can purchase fairly inexpensively a BC-348 in unmodified and running form from many surplus dealers. Many don't list them, since the demand is low. The whole modification can, and *should* be built, starting with the basic BC-348, and adding to it, checking out each phase as you go.

Basic Changes

Due to its airborne service, as part of the AN/ARC-8 Liaison Radio Group, the filaments are wired for 28 V dc and the B+ was derived inside the unit from a dynamotor. The dynamotor (ugh!) must go, and it is the second thing you will accomplish. The first? Get a schematic and get very familiar with the unit. Follow the signal, B+, and filament path, etc., through in your mind and locate components on your chassis. This saves many headaches later. Now carefully remove the dynamotor and tag or identify where all the leads attached into the chassis. From this point, most modifications start you rewiring the filaments for use with 6.3 V ac. Remember what a small amount of ac does to mask a very small signal? Better you spend your time building a 20 to 28 V dc regulated supply on the board shown with this article and leave the filaments on dc! Besides, there are many wires down in the i-f region of the chassis, and some if moved change alignment, BFO injection, etc. With this same

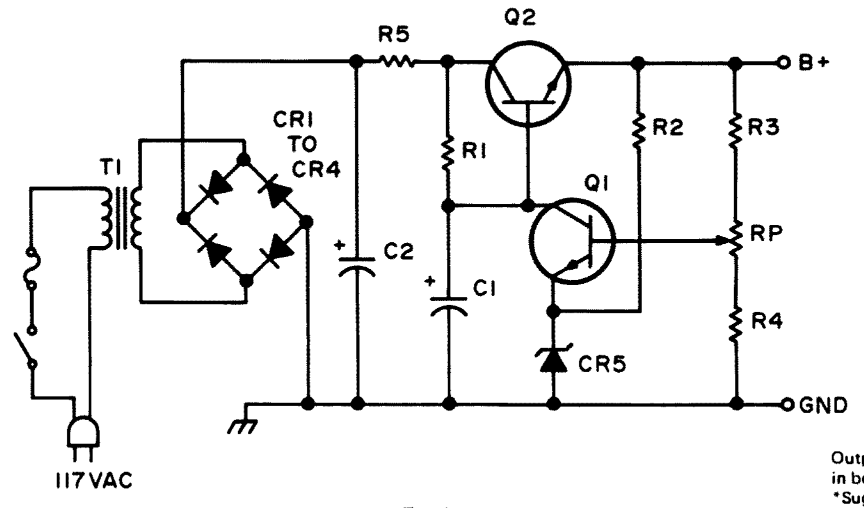

Fig. 1.

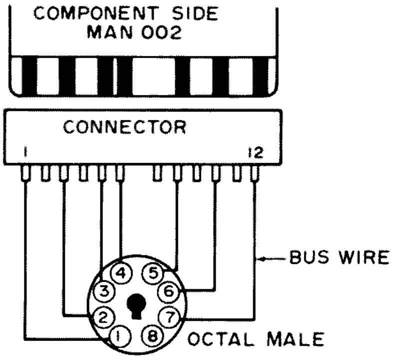
POWER SUPPLY VALUES

	28 V dc Version	160 V dc Version
T1	24 V ac 1.5 A	135 V ac 100 mA
CR1 to CR4	75 V 1.5 A	300 V 150 mA
C2	4000 to 8000 uF/50 V	500 uF 250 V
C1	100 uF/50 V	100 uF 250 V
R5	6 to 10 Ohms/7 W	56 Ohms/3 to 4 W
R3	22 Ohms/½ W	2700 Ohms/½ W
R4	"	"
Rp	220 Ohms/3 W	27k/1 W
R1	560 Ohms/1 W	8200 Ohms/½ W
R2	330 Ohms/½ W	6800 Ohms/½ W
CR5	20 V/400 mW	100 V/1 W
Q2	*Motorola MJ series (MJ1001) 50 V/2 A	Motorola MJ series or MPS U10 250 V/200 mA
Q1	Motorola MJ series (or 2N3053) 50 V/250 mA	Motorola MJ series or MM 3009 250 V/50 mA

Output voltage dependent solely on components loaded in board.
*Suggest use with moderate heat sink (i.e., power supply aluminum chassis).



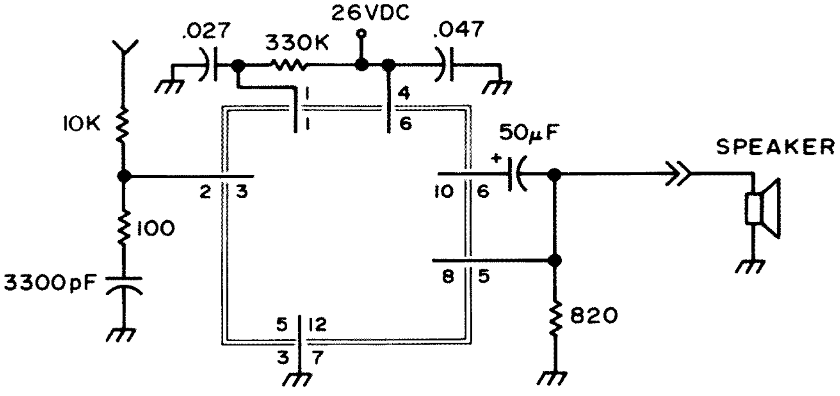


Fig. 2.

board and the second set of components listed, build the 160 V dc regulated supply. Follow the schematic and board loading diagram carefully, since this is the only "building" involved in this article. The lower than usual B+ is no accident. Two reasons most conversions ran the 210 to 255 V dc for B+ was they saw it on the original schematic, and to some degree it was required by the audio output tube. To eliminate the latter need, I have included what I feel to be the best way out of the "headphone audio" found in many surplus sets. In fact it actually eliminates the biggest heat producer in the chassis and ups the audio to speaker level in one blow.

Audio Changes

Fig. 2 describes a solid state audio system that drives a 35 Ohm speaker to as much audio as you could ever need. The speaker and the module to be described can be purchased from radio-TV service stores as an RCA replacement item. It fits into the same octal socket (with an adaptor you make), and gives off considerably less heat. This audio system runs reliably from 28 V dc, so now you know two reasons for leaving the filaments on 28 V dc. It can be purchased for less than you could build it, and definitely cheaper than replacing the output tube when it burns itself alive! The module is known as MAN 002, Sound Output, Part # 133455, and its socket used in making the adaptor is a 13 pin PC board inline, Part # 133634. Buswire is used to connect the inline to a male octal per Figs. 2 and 3. The module only draws 10 to 60 mA idle to wide open. You must rewire the audio output octal socket in the BC-348, but this is much easier than trying to pull it out and notch out the aluminum chassis (HA!). Do it in the following order and it goes quickly.

Removal

Remove the B+ leads from plate and screens, pins 3 and 4. Remove the audio output transformer. Remove the filament leads from pins 2 and 7 and note which is ground. Leave the ground connected at the ground end. Trace hot side to previous tube, and replace with same type of wire (same I capability) only long enough to reach to the area where the audio transformer was. Mount a terminal board having one insulated terminal and a ground in that area and mount on it a 15 Ohm/4W resistor, connecting one end to the extended lead and the other end to ground. This keeps the 28 V dc filament string series correct. Remove the lead to pin 1 to ground. Leave ground end connected. Remove lead from pin 5 (audio in) and don't lose the point the other end of this lead goes to. Remove lead to pin 8, both ends. Pin 6 is already unused and should be blank.

Rewiring

Install a 100 Ohm ½W resistor in series with a 3300 pF disc ceramic capacitor between pin 2 and a ground lug. Replace the lead that went to pin 5 (audio in) with a 10k ½W resistor with spaghetti over the full length leads and run to pin 2 same as the above connection which was a high frequency roll off filter. Use the wires left grounded in the removal process to ground pins 3 and 7, using the closest one to each pin. Wire a 330k ½W from pin 1 to 4. Wire a .027 uF paper or mylar 100 V capacitor from pin 3 (gnd) to pin 1. Wire a .047 uF (same type) from pin 7 (gnd) to pin 4. Run a lead (orange-for second highest B+) from pin 4 to a new power connector. I suggest a Cinch Jones 12 pin type P-312-CCT. This is a hooded plug so the cable can leave the chassis through a grommet hole and plug in at the power supply. The power supply chassis mount mate is a CJ type S-312-AB. Wire a 50 uF 25 V dc electrolytic capacitor with plus to pin 6 and minus to pin 5. Spaghetti may be needed on the leads. Wire an 820 Ohm ½W resistor from pin 6 to ground lug. This is a fixed load on the audio output. Speaker leads should be attached to pin 6 and ground and led to the new plug. Do not allow the lead from pin 6 to touch ground while receiver is on as this is a transistor output stage. That completes the change except for plugging in the adaptor and module.

Since SSB is around to stay, there is one modification that *must* be made to a BC-348 to use it effectively. Obtain a 350k audio taper pot and place it in the hole where the dial light dimmer pot is located. Remove and discard the dimmer and wire the bulbs direct (bypassing the pot). Extend the audio leads up through the hole used for rf section to i-f section leads (under the BFO switch). Mark this pot as volume or audio and remark the original dual pot rf gain. This way full or high audio can be used with the rf gain used to control i-f-BFO mixing levels.

That completes the BC-348 T M-1 and M-2 modifications. Ours is up to M-12, although several of the other 10 are somewhat specialized for Oscar and EME, such as full AFC, auto scan, motor control remote tuning, added i-f for panadaptor and discriminator meter – AFC take off, recorder drive, multi-audio out for record, etc. Each of these were added at very little cost, yet we

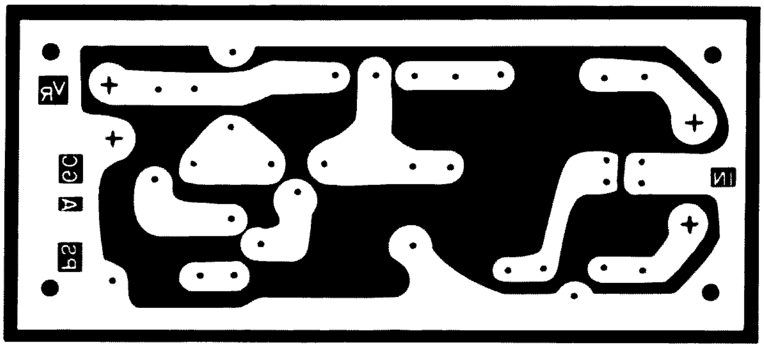

Fig. 3(a). PC board (full size).

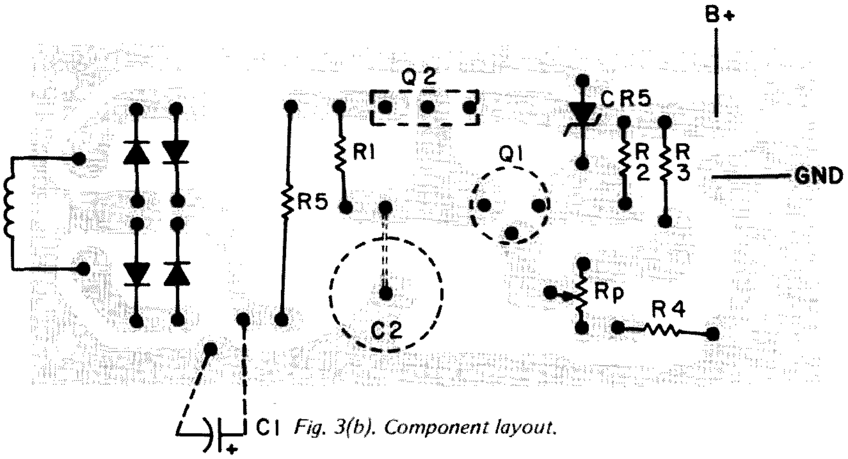

Fig. 3(b). Component layout.

now have a receiver comparable to that used at ground tracking military stations.

I hope to continue with follow up articles on the BC-348 T and other of our EME equipment to help generate interest in EME and the fascinating world of Oscar, and convince you that there are inexpensive ways of participating in these projects cheaply and without a huge antenna farm on your lot. I would be happy to help in any way I can on the BC-348 modifications in this article, but please make the questions as clear as possible and confine them just to these modifications and not the BC-348 as a whole. Don't forget an SASE.

Happy and "quiet" listening on your new breed "junque" receiver. ■

Cx

Because of the Canadian postal strike, last minute corrections to "RTTY Autocall — the Digital Way" (February, pp. 76-82) were not received in time for publication. The corrections are as follows:

- Page 76. The correct code for Calgary is T3A 3A9.
- Page 76, col. 1, line 20. Should read, "diodes, ICs and many resistors and."
- Page 76, col. 2, line 10. Should read, "units) such features as the NNNN shut."
- Page 77, col 1, line 4. Should read, "as keyboard-operated perforator turn on/off."
- Page 78, Fig. 2. "AA IN" and "CA IN" should be reversed. Also, "FORCE ON C" should have been inserted connecting to the top 7474, in a fashion the same as for the connections of "FORCE ON B" and "FORCE ON A."
- Page 79, col 1, line 30. This note should have been added at the end of the "Clock" paragraph: "If, when first powered up, the clock does not start, momentarily ground pin 15, V4. This will allow the clock to run through once. Operation after this will be normal."
- Page 81, col. 1, line 5. Should read, "printed circuit board that is stacked on top of."

A PC Board Bonanza

The amateur experimenting with solid state projects certainly must have a well stocked junk box these days. Higher minimum order requirements, spiraling prices, failure of distributors to stock catalog items and slow delivery have left many of us with unstarted or unfinished projects. And it is getting worse!

The accumulation of tube vintage parts are of little, if any, use in solid state circuitry. On the other hand most of the mini discrete devices can be used to some advantage in even the latest IC lash ups.

The solution to the above, at this QTH anyway, is surplus PC boards. Let the buyer beware! There are circuit boards and then there are circuit boards. Keep away from the encapsulated board as well as the older and larger boards for obvious reasons.

As an example of the circuit board bonanza, I have acquired and stripped (with 85% recovery of parts) over sixty boards within the past six weeks. They were the small 2"x2½" computer boards, look new and were probably thrown out due to an imperfect test or were replaced by modern circuits. I kept a record of the most recent batch stripped. Here are the results. Out of 23 boards, costing $2.90, the following components were recovered:

126 transistors, mostly plastic, GP or switching types such as 2N3638, 2N3640 and 2N3646 or equal.

343 resistors. 290 were ¼ W 5%, others were ½ W 5% or ¼ W 1%. All good values.

61 capacitors. 45 were Mylar and 18 were SM midgets. 5 were Erie piston trimmers, each with a catalog price in excess of that paid for the whole batch of boards.

171 diodes, both silicon and germanium, equal to 1N914, 1N60 and 1N270, etc. Several were zeners in the 4 to 8 V range.

22 right angle, 15 pin connectors. These are perfect for joining a display board to a main board for counters and clocks.

As I mentioned earlier approximately 85-90% of the recovered components passed a preliminary test, were separated according to type or value and stored in partitioned plastic boxes for future use. Of the small percentage of rejects some were damaged in removal while some may have been defective when received. No component, new or used, is installed at this QTH without prior test. I learned that the hard way.

To accomplish the above high recovery rate takes patience, a good desoldering technique and the proper equipment. All equally important.

Let's start with the equipment. I will first list the minimum requirements then follow up with some very desirable additional items.

The basic tools are as follows: Needle nosed pliers, 4 or 6 inch. These should be of best quality with a sharp needle point, Klein 303-6 or equal; a solder aid/scriber equal to Moody MS-2; a small pocket type screwdriver, Xcelite R-3323 or equal; a small sharp pocket knife; a small vise; and a small soldering iron, such as an Ungar No. 776 with Nos. 1235 and 535 heating elements plus No. 331 and the No. 6940 Princess minitip. (More about this soldering iron combination later.)

The following items would make the work easier and would probably reduce the number of damaged components: A small multiposition vise such as Lafayette's 13P55916 would permit positioning the board at a more convenient angle; a combination bench light and 5" magnifier would help see those tiny leads and reduce eye strain; and a variac or equal would control the soldering iron temperature to just enough for the job at hand.

Now a word about that all important technique: We start with the choice of boards. Look for unencapsulated, 1/16" thick, foil on one side boards containing the items you want. Some transistors are user coded and, until someone comes up with a conversion table, might complicate your selection and testing. The component leads usually are cut about 1/16 to 1/8" longer than the board thickness and crimped before soldering. This is what we want.

We start with the transistors since we have no way of heat sinking them. Set up the 1235 element with a 6950 tip at about 80 V, if a variac is used, so that you have an element full of heat, at a low value, transferring instantaneous heat thru the minitip when it touches the foil. Hold the board in your hand, in a vertical plane, about 6 or 8 inches from the vise, touch the CLEAN tip to one of the foil pads JUST long enough for the solder to become fluid then QUICKLY remove the iron and at the same time tap the edge of the board smartly on the vise. The molten solder will fly off leaving the lead clearly visible. Lift the lead, with the knife blade, clear of the pad to a perpen-

dicular position. This will free the lead. Repeat the operation with the remaining leads in sequence. Do not desolder more than one lead at a time. The time used in lifting the lead allows the transistor to cool off a bit between heats. After the third lead is freed turn the board over and, using the knife blade, pry the transistor from the board. Straighten the leads with the pliers and lay aside for later testing. Remember, too much heat or heat applied for too long a time will ZAP the component.

Next in order of fragility are the diodes. Fortunately we can heat sink them by sliding one jaw of the pliers under the lead, grasping the lead firmly, then as heat is applied to the foil side we lever the diode lead free much as a dentist pulls a tooth. The pulling action straightens out the crimp as the lead comes free.

The same approach may be used on the capacitors and resistors. In some cases the scriber point must be used to lift the lead enough for the pliers to be slipped under it. While removing diodes, capacitors and resistors no tapping is required. Just clamp the board in the vise and use the iron in one hand and the pliers in the other.

The angle connectors are salvaged by using a hotter soldering combination plus the tapping technique to remove the solder before prying them free with a screwdriver. Work from both ends as the connectors are easily broken.

After the stripping operation is completed, sort the components, test and store them for future use. The GO-NO GO testing is done here using the Heath IT-10 Transistor Tester and a Simpson Model 260 Multimeter. An adaptor for the small transistors was made by soldering spring wire contact and leads to the proper pads of one of the stripped boards to allow testing in the IT-10. While the transistor leads are short they will fit thru a 1/16" board perfectly and are of top quality.

Surplus boards are available from many sources and at prices ranging from give away to all the traffic will bear. Select your PC boards with care. If you can't use the parts it's no bargain at any price. ■

Government Surplus: Is It All Gone?

The label on the crate said "Radio Transmitter," and gave the coded model number. I knew that this particular model cost the U.S. Government $1235, and considering the paltry few cents I had bought the crate for, I eagerly pried open the crate and dug through five pounds of packing material to get at my prize. But I found no new radio transmitter. I found instead a dusty, half-empty wine bottle – and a cheap brand at that.

I was understandably disappointed, but not exactly surprised; buying from the world's largest and cheapest department store, the Defense Property Disposal Service, has increasingly become a test of patience, a kind of Russian roulette filled more and more with pitfalls. Sad to relate, the DPDS is rapidly losing its rating due to an apparent shortage of materials. Worse, the quality of the material available is declining, as is the frequency of the sales themselves. Another barometer is the price of the lots; costs have doubled and even trebled within the past few years. To cite some examples: Electronic equipment and spare parts weighing ten thousand pounds went for four cents a pound a year ago; now you will have to pay as much as thirteen cents a pound for the same amount of stuff. Last year, you could buy instruments at sixty-five cents a pound; now the same instruments at surplus will run you well over a dollar a pound. I recently paid nearly twelve dollars a pound for some Hewlett-Packard test equipment – double the rate I paid eighteen months previously.

There are instances to make both the taxpayer and the surplus buyer blanch. A short time ago 345 individual lots of electrical and electronic equipment came on the market. The lots cost the U.S. Government – and hence the taxpayer – just under $8 million. The whole shipment was sold off for $127,000. Much of the equipment was brand new, and most of it was still packed in original containers. Electronic lab equipment, aircraft parts and instruments that the U.S. paid $6 million for was parceled out to surplus buyers for less than $75,000. A good deal for the buyers, a bad deal for the taxpayers.

As staggering as these figures are, they are a drop in the bucket compared with what went on following World War II and the Korean War when you could buy an aircraft carrier at the scrap price of two cents per pound. The catch, of course, is that you had to move the thing yourself; this could be a problem if you lived in Boise, Idaho.

The surplus buyer's problem today is finding lots that contain worthwhile electronic equipment at prices that make their resale really worthwhile. And it's getting tougher all the time. Government contracts for defense have been sharply reduced, and in some cases cut altogether. New contracts for design and manufacturing are practically non-existent. Foreign aid programs have felt the weight of the Congressional axe. The wake of the war in Vietnam left no bonanza for the American surplus buyer; most of the goods left over from that war are being funneled right back to Southeast Asia and, increasingly, to Israel. Only driblets seep back to the country of origin, i.e., here, for sale to the public that paid for them in the first place.

I talked to one of the nation's top dealers in surplus electronics, Ray Kilby, who has some advice for anybody who wants to get into the surplus game. Kilby is an executive with S.P. Airparts in North Hollywood, California, and is ranked among the most prolific buyers of surplus materials. Kilby's prime concern is stockpiling parts and units against the day when the surplus supply is truly exhausted. To beginners who are contemplating bidding on their first batch of surplus as an entry into the game, Kilby has this to say: "Don't! It takes more years to learn the *little* things about this business than it does for any other professional to learn the *big* things about his profession. You don't stand a chance – unless you happen to be wildly lucky. Competition is pretty fierce right now, and is not liable to lessen. The average man can't plot a money-making career by waiting around to get lucky, and luck is the name of the game for the amateur surplus buyer."

If you decide that your luck is running good and want to go against veteran Kilby's advice, bear in mind that Government stocks are not as large as they have been in years past, and that you will be bidding against the pros–guys like Kilby. It's better, and safer, to buy the odd piece from your local junkyard or surplus store. Begin your own stockpile of items that will grow in value. Those ten-for-a-dollar printed circuit boards won't be around much longer. The $20-$30 receivers and transmitters that, with a small conversion, were so popular with hams and SWLs,

have all but vanished from the shelves. The latest government receiver on the market has a digital readout and goes for anywhere from $500 to $1400, depending on the condition. And there are not a great deal of even these expensive items available.

The top-ranked test equipment is just not making it to the shelves; most is being gobbled up by companies who are in the business of reconditioning and resale for a staggering price that can be afforded by a corporation, but not by the hobbyist or small businessman. Another factor facing the small buyer is the sheer sophistication of the equipment that sometimes becomes available; some of it is so specialized that it is useless for any function other than the one it was designed for.

Okay, so the picture is a little dark for those who might like to break into the surplus field as a career. This doesn't mean that the hobbyist or the inveterate do-it-yourselfer has to forego the pleasure of the hunt or the personal rewards of scouting for bargains. They are good buys in some items that haven't made it to the commercial field of electronics and won't have any industrial use until the advances made in military electronics are made available to the consumer. What we are talking about is real war surplus: overruns, over-purchased and over-ordered electronic equipment designed for the military, usually developed far in advance of the consumer market. Some of this stuff is really a stripper's delight, containing as they do many of the newer solid state devices that have a healthy price tag when bought new. A few power supplies are surfacing among the unidentifiables, and most have low voltages and are near-perfect for transistor applications.

A recent report from the West Coast reveals that the U.S. Government is bulldozing tons of good electronic equipment and turning it into a mass of unusable junk. The electronic equipment, ground to bits, was worth millions, destroyed, the Government says, because it had not been "demilitarized." In government jargon, to demilitarize is to render equipment unusable in its original form. In the past, a technician demilitarized a piece of equipment by using a pair of side cutters to snip off a plug or remove a meter. The equipment was rendered inoperable – but it *was* repairable. Unfortunately, this method of demilitarization has been brought to an end; the equipment is simply destroyed beyond redemption. Sadly enough, there are instances where the identical equipment can be purchased across many electronic dealer counters in pristine form – but for outrageous prices. If the public could have access to the plowed-under electronics, purchasers could have a real break on a fair-bid basis. What to do? Write your Congressman. If the present policy continues, the shortages will become even greater, the prices higher. It could come to the point where the great middle ground will vanish, leaving the individual purchaser no choice but outright junk or goods priced above his head.

Until that day comes, here are a few basic guidelines to the surplus shopper. When examining items, pay close attention to the way the crates are tagged. The items are tagged with one of three colors on tags about 3 x 8 inches. *Yellow* means that the described item is new or in operating condition. *Green* indicates an item that doesn't work, but that is repairable. A *red* tag means disaster; even government technicians are unable to fix whatever is wrong. These tags are usually correct, and a quick glance can save you plenty of grief. But remember that the really good stuff is going out the back door as soon as your local surplus dealer unloads the truck. The big dealers are there, waiting and, as the shortages grow, so will the lines of those waiting for good deals. Your best bet is to cultivate the friendship of one dealer; most will save wanted items for faithful customers.

If the flow of surplus material continues to choke off, many dealers who have had second homes at redistribution centers will fade from sight. Buildings and property around these once-bustling centers will become vacant. The employees, once junkmen, will become junkmen again. Leaving the empty warehouses, they will take to the roads in flatbed trucks, looking for junk. They will be hoping that someday the good times will roll again.

If there's another war, that is. ■

An accurate wind speed indicator (anemometer) is especially difficult to design. The most significant problem becomes apparent when very low wind speeds are involved. The most common anemometer is the rotating "cup" device that in turn drives a small generator or electronic indicating device. The "cup" anemometer, at low wind speeds, must be very efficient (wind capture wise) and have little friction so as to detect low wind speeds.

The accepted reference for wind speed indication is a tube of a known diameter bent at a 90° angle which then directly feeds an air pressure meter. Of course, this tube must face the oncoming wind directly at all times and all tube dimensions must be taken into consideration. The air pressure meter readings are then converted to wind speed in

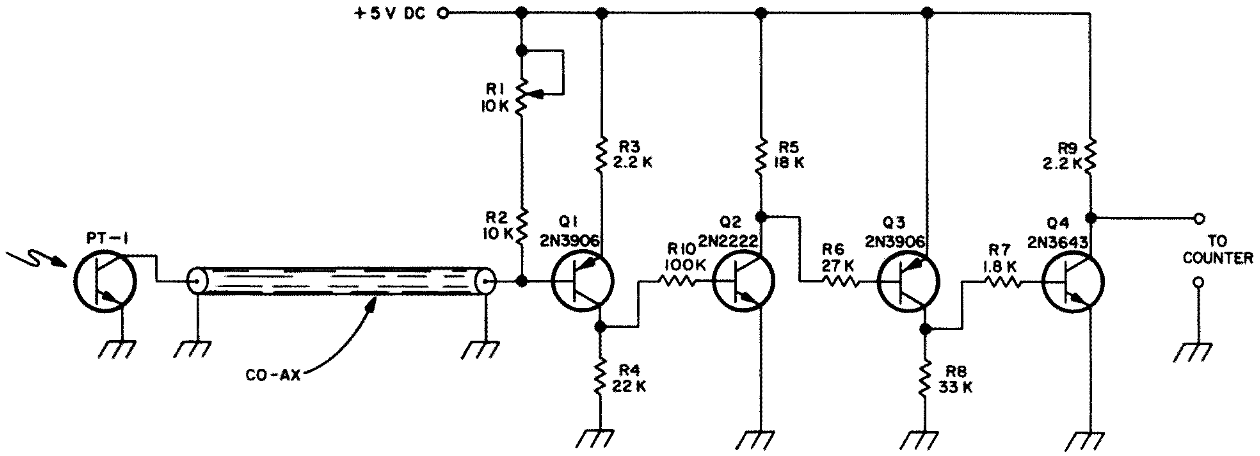

Fig. 1. Anemometer light activated trigger. PT-1 – Radio Shack FPT-100 phototransistor; Q1, Q3 – 2N3906 NPN silicon transistors; Q2 – 2N2222 NPN silicon transistor; Q4 – 2N3643 NPN silicon transistor, R1 – 10,000 Ohm trimpot; R2 – 10,000 Ohm, ¼ Watt carbon resistor; R3, R9 – 2200 Ohm, ¼ Watt carbon resistors; R4 – 22,000 Ohm, ¼ Watt carbon resistor; R5 – 18,000 Ohm, ¼ Watt carbon resistor; R6 – 27,000 Ohm, ¼ Watt carbon resistor, R7 – 1800 Ohm, ¼ Watt carbon resistor; R8 – 33,000 Ohm, ¼ Watt carbon resistor.

Wind

miles per hour, depending on air density, temperature and whether or not a bird is resting on the tube (coefficient of air friction depends on size of bird, number of feathers on body and how many seeds he has eaten the day before – owls excluded due to excessive mass).

Various other types of anemometers have been created. For example – those that expose an electrically heated wire to the wind and then measure the specific resistance of the wire. As the wire is cooled by moving air, the resistance would change accordingly.

The average ham shack in this day and age possesses a digital frequency counter with at least a one second input gate time. (If not, begin construction of one immediately.) Now, assuming that you have a frequency counter, you also need a device planted on your roof top that follows the wind speed and will produce one pulse every second when the wind speed is one mile per hour.

Creating a pulse that will trigger the counter is not much of a problem. Devising a way to generate this pulse at one time per second at one mile per hour is another story. We decided to generate the trigger pulse by using a rotating disc with a single hole drilled in its periphery to admit a light pulse. If a light emitting diode was placed above the rotating disc and a phototransistor below the disc, the hole would pass pulses of light as the disc was rotated. Phototransistors are very responsive and fast switching devices.

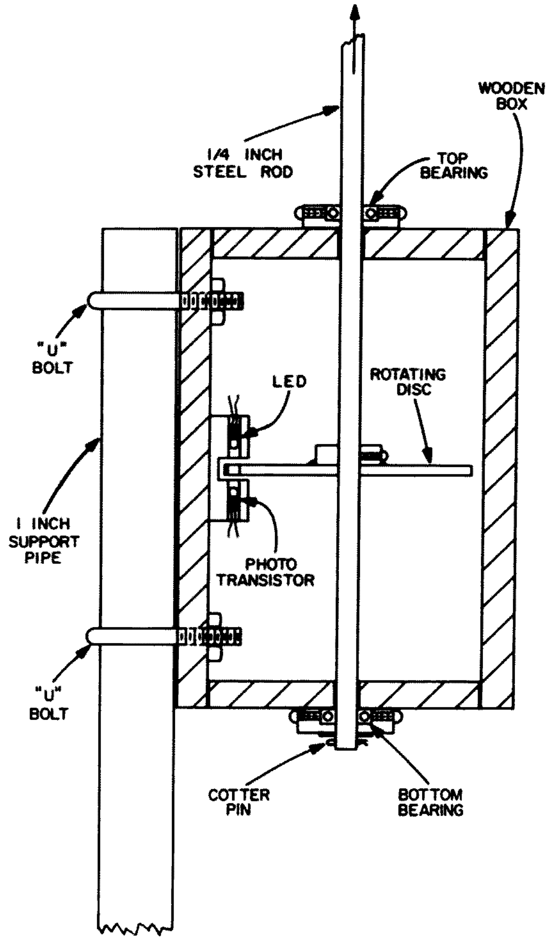

Fig. 2. Main indicator assembly.

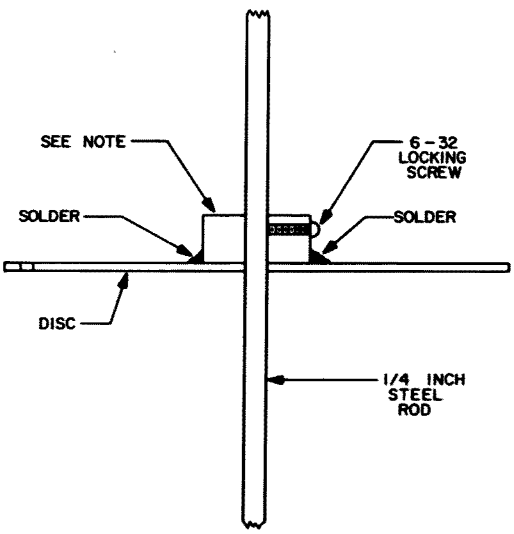

Fig. 3. Disc to shaft attachment.

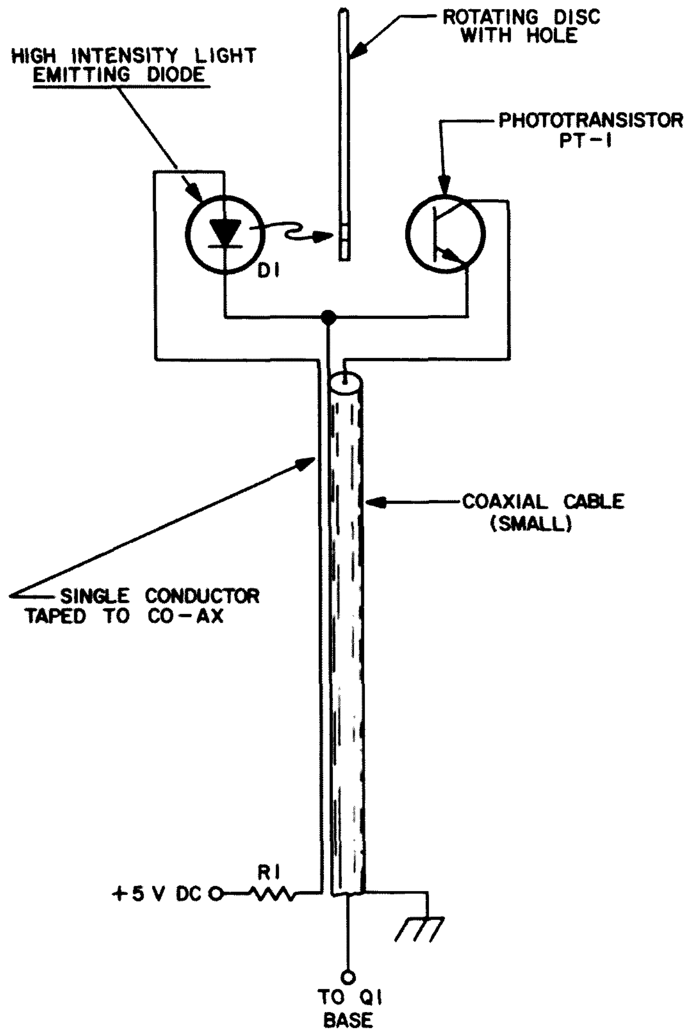

Fig. 4. LED – phototransistor cable. D1 – high intensity red light emitting diode (any bright clear red LED); PT1 – FPT-100 phototransistor (Radio Shack); R1 – 220 Ohms, ½ Watt carbon resistor; Coax – RG/59U or smaller. Miniature mike cable will also work.

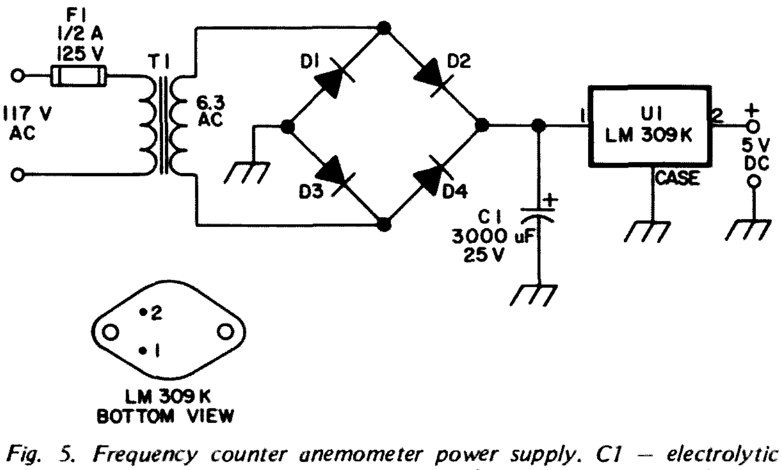

Fig. 5. Frequency counter anemometer power supply. C1 – electrolytic capacitor; D1-D4 – 1N4002 silicon rectifiers (50 V, 1 Amp or more); F1 – slow blow fuse; T1 – 117 V ac primary, 6.3 ac secondary 1 Ampere filament transformer; U1 – National LM309K 5 volt voltage regulator.

An LED as a light source should have a reasonably unlimited life span (the LED doesn't have a filament so theoretically never burns out).

The size of the rotating disc and position of the light passing aperture hole was determined as follows:

If the wind speed is one mile per hour, the air molecules must travel 5,280 feet or 63,360 inches in one hour (5,280 feet x 12 inches). Therefore if we have a small disc (friction free) driven by a cup type anemometer, it must have a circumference that would travel one mile in one hour when the wind speed is one mile per hour. If 63,360 inches = 1 mile and 3600 seconds (60)(60) = 1 hour then:

$$\frac{63{,}360}{3600}$$

would equal the distance in inches that must be traversed in one second to equal 1 mile per hour or 17.6". 17.6" would be the circumference of the disc with the light hole exactly at the edge. It is easier to construct a larger disc and drill the hole at the 17.6" circumference point. The diameter of a 17.6" circumference disc would be:

$$\frac{C}{\pi}$$

or 5.6". The radius therefore would be ½ of 5.6" or 2.8" from the exact center of the disc.

We happened to run across a "high intensity" red LED at a local hamfest and used this as the source of light for the phototransistor. Any common garden variety LED should work equally as well, as the dc amplifier following the phototransistor has plenty of gain. Of course the enclosure containing the LED/phototransistor combination must be reasonably "light tight" or extraneous sunlight will produce erratic readings.

The phototransistor used is a Radio Shack FPT-100. These sell in the neighborhood of 79¢. Of course there are many other types of phototransistors available and all are quite reasonable in price.

The FPT-100 phototransistor is capable of very fast response. It has a much faster response time than will ever be required by the anemometer trigger disc. If you want to make sure that the phototransistor is really functioning, attach a light emitting diode to an ac source such as a 6.3 ac filament transformer in series with a 1000 Ohm current limiting resistor. The 1000 Ohm resistor is a nominal value and may have to be decreased to obtain sufficient light intensity from the LED. Place the ac illuminated (modulated) LED directly in front of

the phototransistor and attach the output of the amplifier to your counter. The observed count should be 60 Hz. A more exotic method is to illuminate and modulate the LED with an audio generator. The counter should read the audio frequency directly as the phototransistor responds to the audio modulated LED. This virtually is the same as a photocell detecting audio from varying film density in a motion picture projector.

We have covered the construction of the rotating disc trigger and bearing support assembly. The next device is the rotating "cup" assembly. It is difficult to "peen" soft metal into a perfect cup shape to form the air scoops. We thought of using commercially manufactured soup ladles which are close to the desired shape. However, it seemed wasteful and expensive to hack up four perfectly good soup ladles. It finally occurred to us that L'eggs pantyhose containers are just about perfect for this application. These egg-shaped plastic containers split in half and provide two cups for the anemometer assembly. Therefore two L'eggs containers are required for the anemometer. If you haven't access to these containers, convince the XYL that these are definitely necessary to beautify her legs beyond belief and at least two pair are required should a "run" occur in one set.

The L'eggs halfshell is drilled so as to admit a coathanger wire toward the front half of the parabolic shape. Epoxy cement is used to secure the coathanger wire when inserted through the plastic halfshell. These plastic shells are weather resistant and normal corrosion will not take place. They are light and respond well to wind "excitation."

Fig. 1 is the fundamental C.C. amplifier that senses the variation in resistance of PT-1. This amplifier also provides the pulses of sufficient amplitude to drive a frequency counter. Parts placement is not critical so this amplifier may be constructed as a printed circuit or breadboard. As with any amplifier, the entire assembly should be shielded to prevent hum pickup or other extraneous outside noise.

Fig. 2 illustrates the mast attached box containing the LED-phototransistor sensor and rotating disc. The wooden box should be water and light tight.

The remaining illustrations are self-explanatory when constructing the anemometer.

What we have described is a device that will provide an interesting addition to your present frequency counter. At least it will remind you of when it is necessary to crank down your expensive 10 element 20 meter beam when the wind becomes beyond limits. ■

Stereo - A New Type of CW Filter

by
Robert L. Anderson W8KZM
391 Pleasant Ridge Ct.
Saline MI 48176

Does this sound like a familiar situation? You just installed a narrow band CW filter in your receiver and are now ready for that upcoming CW contest. Comes the weekend, and with it disappointment! Those rare multiplier contacts are still buried with strong QRM on each side. Your new filter is sharp, 400 Hz or so wide, with steep skirts on each side. However, somehow when you tune one QRMing station off on the low side of the filter, the station that was just off the high side is now S9, and the rare DX is still unreadable.

Having been in this situation myself during contests, or even in periods of heavy CW activity, I wondered if there was a way to further untangle the CW signals from each other. My particular receiver is the Heath SB-301 with the conventional 400 Hz CW filter. A still sharper filter might be an answer, but there are problems of dash-dot slurring due to the narrower bandwidth and filter ringing.

I then thought about using a pair of stereo headphones (or two speakers) together with a pair of high Q filters to channel each end of the 400 Hz CW filter passband into separate audio channels, thereby creating a "stereo" effect. It seemed to me that by doing this, it should be possible to use the ability of the brain to distinguish between the signal level arriving at each ear and to "compute" a location in space for the origin of the sound. With such a system, CW signal at 800 Hz would appear to come from the left and 1200 Hz signal from the right. Signals at frequencies between 800 and 1200 Hz would "appear" to come from various azimuth angles depending on the specific frequency as shown in Fig. 1. Tuning across the band, a signal will appear first to one side of the operator, then appear to drift across in front, and finally appear loudest in the other side before disappearing completely. By adding the feeling of spatial dimensionality to an incoming signal, it should make it far

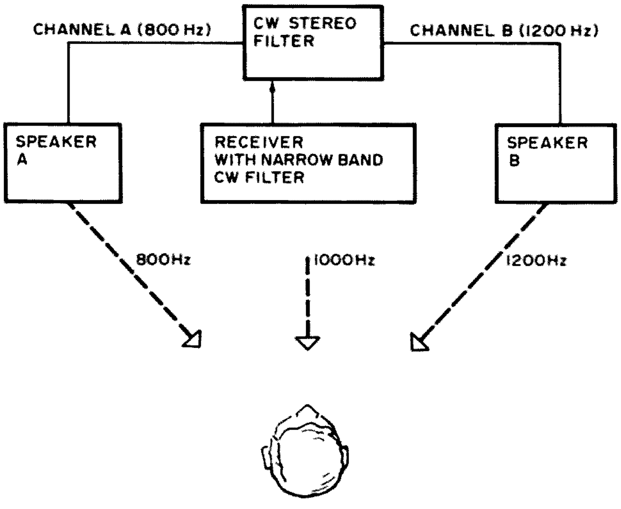

Fig. 1. CW stereo filter in operation. 800 Hz signals come from operator's left, and 1200 Hz signals from the right. Those signals in between (1000 Hz) will "appear" to come from directly in front of the operator.

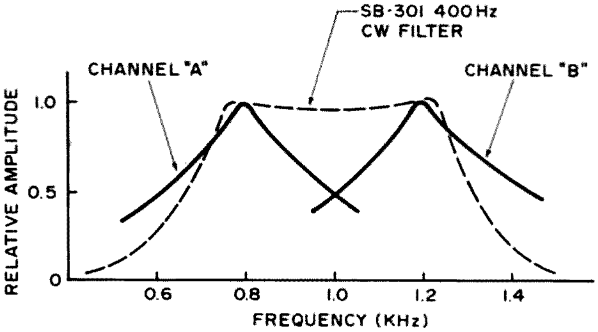
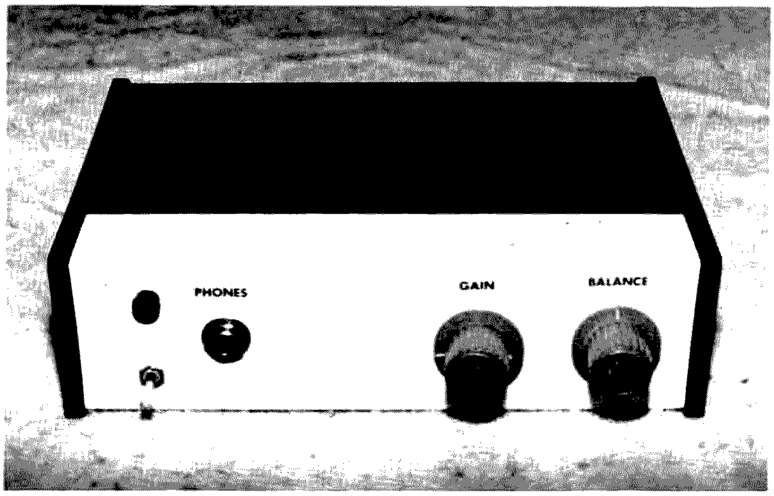
Fig. 2. Filter response curves.



easier for an operator to concentrate on a single signal in the presence of several other QRMing signals on slightly different frequencies.



The Filter

The two separation filters were designed to have the characteristics shown in Fig. 2. One filter was designed to peak at 800 Hz, which is the low end of the passband for the CW filter in the SB-301. The other filter was designed to peak at the high end of the CW filter passband, or 1200 Hz. The Q of the filters was adjusted so that each channel will supply exactly 0.5 of its peak output signal at 1000 Hz.

The Circuit

The circuit for accomplishing this is relatively straightforward, and uses 88 millihenry toroid filters to divide signals into the two separate frequency dependent channels. The entire circuit (see Fig. 3) consists of a single LM3900 quad operational amplifier and two power transistors for active components. The first amplifier section is simply a linear preamp to assure adequate voltage levels at the filter section. The two filters L_1, C_1 and L_2, C_2 are the 1200 Hz and 800 Hz filters respectively. Two more amplifiers buffer the outputs of the two filters and drive the bases of the output transistors Q_1 and Q_2.

Since stereo headphones are generally low impedance (4-16 Ohms), some extra current gain, provided by Q_1 and Q_2, is necessary. If, however, high impedance headphones (2,000 Ohms) are available, or fabricated by rewiring a pair of standard high impedance headphones, then Q_1 and Q_2 could be eliminated. Don't forget to keep the 35 uF blocking capacitors in the circuit, however!

The 3900 Quad Operational Amplifier

For those unfamiliar with the LM3900, a few words on its design are in order since it is unconventional and understanding the principles of its use will be of help in troubleshooting the circuit. The LM3900 consists of four high-gain linear operational amplifiers in a single 14 pin DIP package. Each amplifier has a unique input circuit, called a "current mirror" rather than the conventional differential transistor pair. The LM3900 is designed to operate from a single supply. A schematic showing the connection of one LM3900 amplifier section as an ac coupled amplifier is shown in Fig. 4.

Correct dc biasing of the LM3900 is accomplished with R_1 and R_2. The amplifier output dc level is usually set to be equal to one-half of the supply voltage to give maximum ac signal swing. R_1 is selected to give approximately 10 uA of current into the positive input port, which acts essentially like the base of a NPN transistor:

$$I_2 = \frac{V_s - 0.6}{R_1}$$

With R_2 connected, the amplifier output will increase until $I_1 = I_2$, assuming amplifier saturation does not occur first. The LM3900

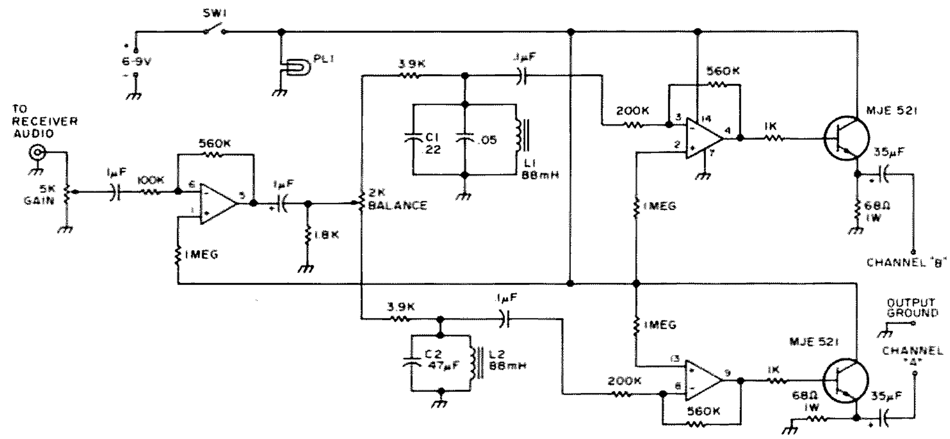


Fig. 3. Schematic of stereo CW filter. All resistors ¼ Watt, 5%, except where noted.

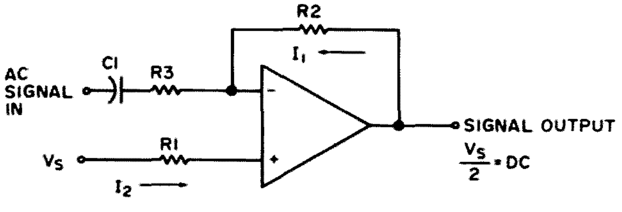

Fig. 4. The LM3900 as an ac coupled amplifier.

operational amplifiers operate on a current input balance and not a voltage input balance as do other amplifiers.

Since: $I_1 = I_2$ and $E_{out} = E_s/2$

then $R_2 \cong R_1/2$

The ac gain is set by: $G_{ac} = R_2/R_3$

And C_1 is selected such that for the lowest frequency of interest (f_{low}):

$$C_I \geqslant \frac{1}{2\pi (f_{low})\ R_3} \quad X\ 10$$

The Hardware

The circuit was built on a PC board and then mounted on a Ten-Tec Model JW-8 (6" x 8" x 2½") cabinet. The gain and balance controls were mounted together on the right side of the front panel and the power switch, pilot lamp and three circuit phone jack on the left. See photo of the unit. The circuit can be powered by either a 6 or 9 volt battery or an internal 6-9 V dc, ac line power supply. The dc current requirement is approximately 200 mA.

The Results

The initial tests of the CW stereo filter were made using a pair of 16 Ohm Utah compact hi-fi speakers spaced about 4 feet apart and 2 feet above the operating position. The results were quite dramatic! The entire shack seemed to "fill" with the sound of the receiver background noise and CW

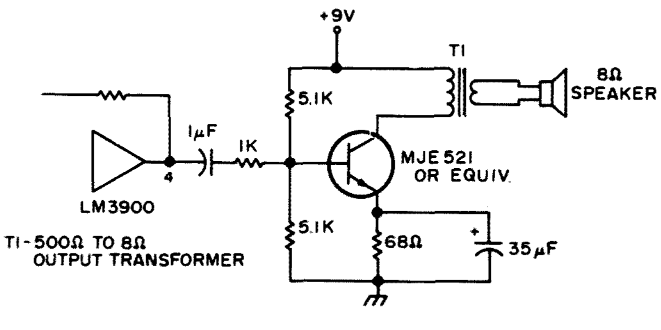

Fig. 5. Optional output stage (2 required). T1 — 500Ω to 8Ω output transformer.

signals, giving a feeling of listening depth never experienced before. Tuning across signals in the crowded portion of 40 meters, signals did indeed appear first on the left, seem to drift across the operating position and then dominate the right side. Tuning in two signals, less than 400 Hz apart, there was a definite dimensional quality to the signals. It seemed very much easier to concentrate, for example, on the W6 coming from the left and the CR6 calling CQ DX coming from the middle right hand side.

Speaker phasing is quite important, and a noticeable change in the "signal-in-the-middle" effect was noted if the speakers are out of phase at 1000 Hz. When first setting up the system, experiment with the speaker phasing by reversing the leads to one of the speakers to see which configuration produces the best "signal-in-the-middle" effect at 1000 Hz. When the speakers are phased correctly, a 1000 Hz note should appear equidistant between the two speakers, and the signal should make a smooth transition between the two speakers when sweeping between 800 and 1200 Hz. There should also be a noticeable improvement in the "dimensional" effect when the speakers are phased properly.

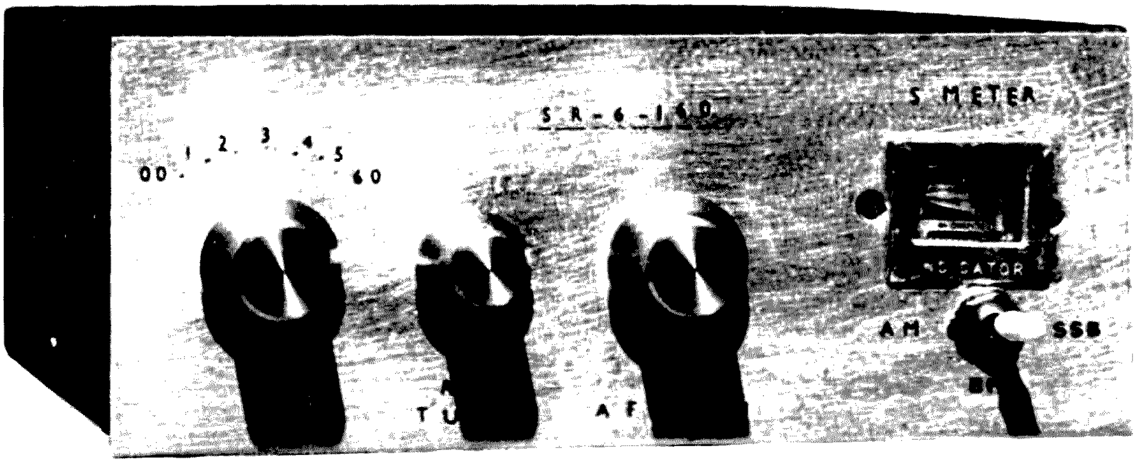
If sufficient sound level cannot be obtained without distortion, then a higher output driver stage, such as the one shown in Fig. 5, is recommended.

The results using a pair of stereo headphones were not quite as dramatic as with loudspeakers, yet were still quite effective. Some of the "dimensionality" appears to be lost by using headphones, yet the separation of signals into the right and left hand channels is still quite apparent. Again, some experimenting with the headphone phasing is necessary to achieve the best effect. Since most stereo headsets employ a common ground, the connections may have to be reversed inside the plug or one headphone itself.

And Some Conclusions

This circuit is, I believe, a somewhat unique approach to the problem of separating QRMing in CW signals from each other. I would be interested in hearing from anyone else who decided to try this circuit to learn what their results and experiences were.

Further improvements can no doubt be made to this initial concept. One possibility is the addition of a third center speaker channel tuned to 1000 Hz to improve the dimensional effect. This would work, obviously, for the speaker method only, unless you have somehow been uniquely blessed with three ears! Also, I can supply PC boards for the circuit described in this article for $6.00 each. ■



160m Solid State Receiver

by
Jim Wallich VK3ANY
154 Balwyn Road
Balwyn, 3103
Australia

Reprinted from *Amateur Radio*, The Wireless Institute of Australia, October, 1974.

It was decided to build a receiver rather than to convert a broadcast band "tranny" as it was considered that the normal cheap transistor portable would lack some essential refinements as well as sensitivity. What was aimed at was a set of such design that could be easily duplicated and therefore was not too complicated and did not require critical adjustment. Sensitivity was to be comparable to any good communication receiver and selectivity to be adequate for present activity in the VK3 area.

With these standards in mind a design which appeared some time ago in a British magazine was used as a basic format. By certain modifications and by leaving out what were regarded as superfluous refinements, an excellent "bird's nest" was produced on the bench and in due course this was drawn up and built on a printed circuit board. The final circuit is shown in Fig. 1. Tests carried out by VK3GK were so successful that the design is offered for the consideration of other amateurs.

Circuit Description

Firstly, it was decided to use germanium transistors as a number of these were available and had to be used up. Secondly, as an audio strip was also available this was incorporated into the unit although the enterprising builder can readily build his own.

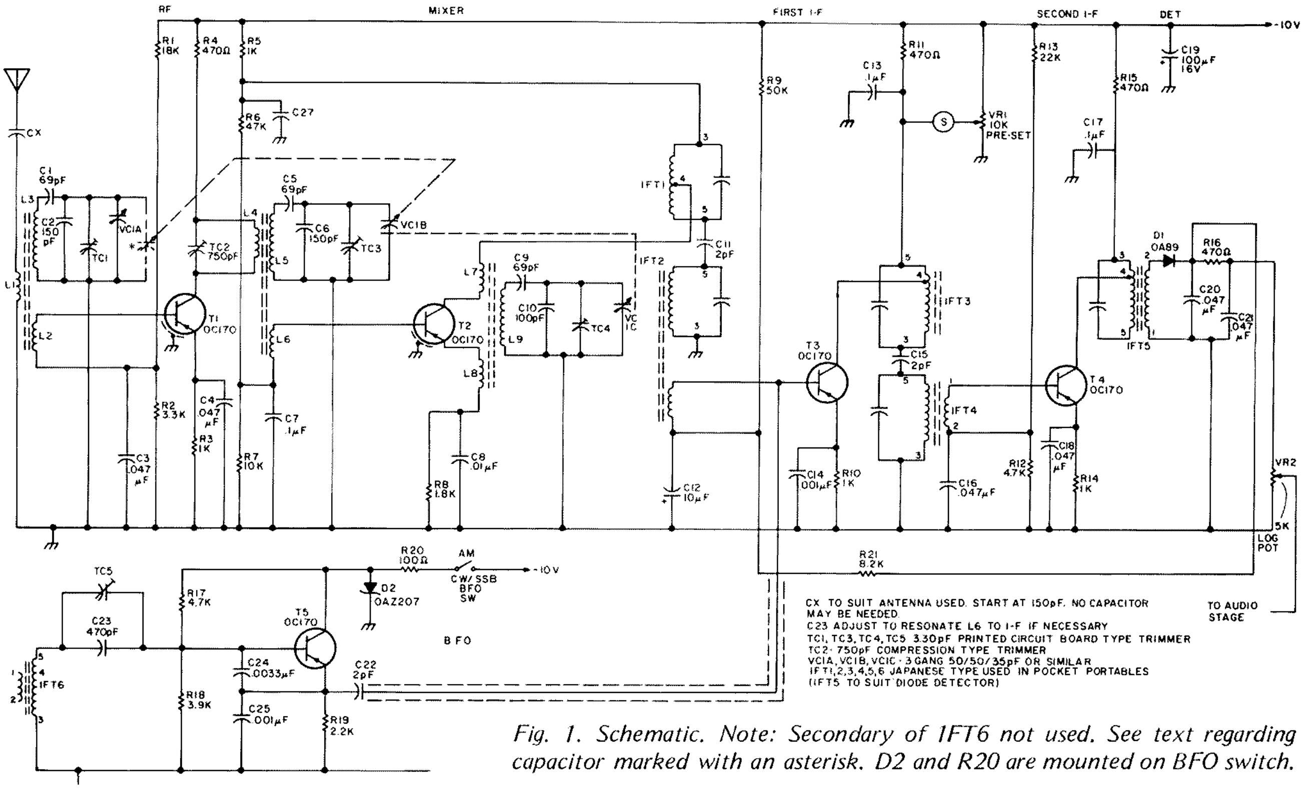


Fig. 1. Schematic. Note: Secondary of IFT6 not used. See text regarding capacitor marked with an asterisk. D2 and R20 are mounted on BFO switch.

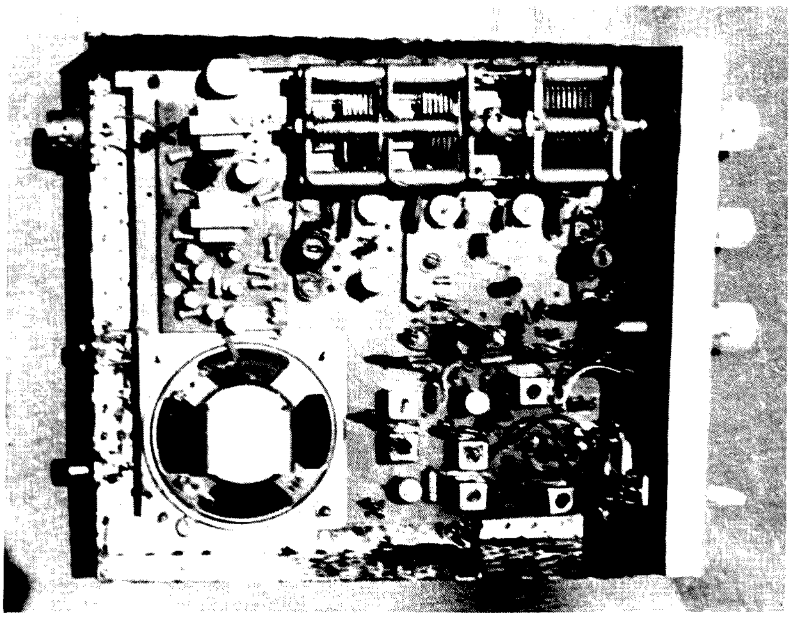
The space on the board will easily accommodate one of the audio ICs now available. A little circuit designing is all that is required together with some modification of the PCB. A small (2½ inch) speaker could, it was discovered, be fitted to the board.

As will be seen the circuit follows conventional design. VC1A, VC1B and VC1C are ganged. Additionally, as shown, there is a small peaking capacitor across L3. This was found most useful as it compensates for any poor tracking that may occur when exact component values are not used. This capacitor may be 10 to 15 pF. It has been suggested that VC1A could be separate from the other two tuning capacitors in view of the difficulty and expense that may be encountered in obtaining a 3 gang unit. In practice such an arrangement does leave quite a lot to be desired as when it is off tune it really masks signals and consequently weaker signals may be missed. If a 3 gang cannot be obtained then one may be made up from a 2 gang and a single gang.

The IF transformers came from discarded broadcast receivers and are the small 5 pin type. It will be observed that in the case of IFT1, 3 and 5 the collectors are connected to the tap nearest to the cold end of the primaries. The resistance from the tap to coil is about 1 Ohm and the resistance from the tap to the other end is 2 to 3 Ohms. There are several different configurations for these transformers as shown in Fig. 3. IFT1 and 5 used in the receiver are type A whilst IFT3 is type B as illustrated. The constructor will have to check this point when selecting his IFTs.

At first sight the AVC circuit may appear very lightweight. However it is in fact very



Top view, showing placement of major components.

effective and no blocking occurs even on the strongest signals. The "S" meter uses a tuning indicator/battery level indicator from an old transistor set. Even when purchased new they are cheaper than ordinary meters; they are small and give a perfectly satisfactory indication of signal strength. The meter is adjusted to read half scale for an S9 signal and zero with no aerial connected. The BFO presented quite some difficulty as it was found that the fourth harmonic of the oscillator came out on 1820 kHz. Eventually a cure was found by tuning the IF transformers to the lowest possible frequency with the aid of a signal generator. This worked out to about 448 kHz. The fourth harmonic of the BFO thus moved to 1792 kHz – below the amateur band. Consequently no screening or special care is required and the BFO works very well. The BFO uses the same type of IFT as the IF except that the resonating capacitor is removed. (Gouged out is the only way I can think of describing the operation.)

The section reserved for the audio strip can be changed to suit the builder's own requirements particularly if he makes up his own audio stage. Remember that a screened lead must be taken from VC2 at the front panel to the PCB. The –10 V supply and earth wire must also be taken to the audio strip and wires run to the speaker from the audio output. The audio strip is fixed to the PCB with nuts and bolts together with spacers. The speaker is mounted on the component side of the board so that when the board is laid copper side down the cone faces downwards.

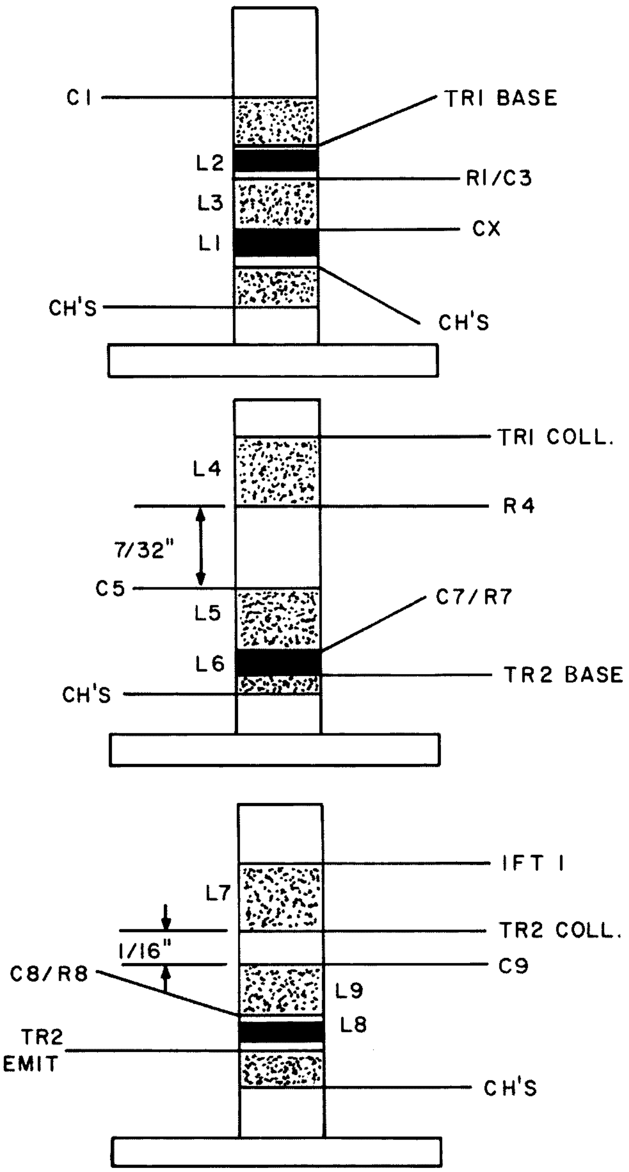


Fig. 2. Aladdin 804 formers. Coil wire #32 SWG enameled. L7 10 turns, L8 3 turns, L9 45 turns, L5 45 turns, L6 3 turns, L1 3 turns, L2 3 turns, L3 45 turns.

Construction, Adjustment and Tuning

Location of the main components on the PCB is the first step. Obviously a decision has by now been made on the ganged capacitor. Coil formers (Aladdin F804) are screwed to the board and the coil terminal pins either passed through holes in the board or soldered to pins as used on veroboard. The construction of the coils is not too critical; however, the dimensions should be followed as closely as possible. Above all ensure that the coils are connected properly. TC2 is soldered into circuit. A hole must be drilled through the board to allow the screw protruding from the underside to pass through.

Special care is necessary in drilling the holes for the IFTs. There are seven holes to each, which includes 2 for the solder tags on the can. Make all holes somewhat oversized as this simplifies the job. Do not overlook the fact that the can tags pass through holes in copper "lands" left to ensure an earthed soldering point. Wherever possible mount resistors (all ¼ Watt) in a vertical position to reduce space usage.

Once all components have been fixed in and a thorough check has been made, connect VR2 and switch on the supply voltage. DO NOT connect the BFO at this stage. Check that the current drain is not excessive and that the base, emitter and collector voltages are satisfactory. Obviously, if all is well, some kind of noise should emanate from the speaker, though this may be only a click when a screwdriver or probe is touched in a sensitive area.

If a VTVM is available confirm that T2 is oscillating. A lead brought from the antenna terminal of the station receiver to the

vicinity of L9 will give an indication if the receiver can tune around 2.3 MHz or a harmonic of this. The oscillator should cover 2240 to 2310 kHz.

Autodyne mixers can be tricky sometimes even when correctly wired. If difficulty is experienced and you are certain that the wiring has been correctly executed it will be necessary to fiddle around to get the stage to "fire." Once it does it will be a "goer" ever after and give no trouble.

Adjustment of the rest of the receiver follows standard practice, but remember what was said about the BFO earlier. Line up the IFTs using a signal generator on a frequency of 450 kHz or lower.

Injection of a signal from the signal generator in the area of L5 enables the mixer stage to be aligned. The same applies to the rf stage.

Alignment of L4, L5 and L6 together with TC2 requires some explanation. The positioning of L4 is arranged to give a limited degree of coupling. If the slug of L5 is unscrewed too much it increases the coupling to a point where oscillation occurs. Therefore once the basic alignment has been achieved, set TC3 to mid capacitance, screw in the slug of L5 practically all the way to the bottom of the coil, and adjust TC2 for maximum signal. Then unscrew the slug to peak the signal and again adjust TC2. This procedure should be followed until the stage oscillates. Screw in the slug to restore stability and readjust TC2. It should be possible to vary TC3 through maximum signal without oscillation occurring.

Initially C14 was 0.1 uF. It was found, however, that when IFT2 was peaked there was instability. By changing C14 to 0.001 uF the stage became docile.

It should now be possible to receive a signal though it may be necessary to wait for an amateur station to come on. Good results can be obtained even using a poor antenna such as a few feet of wire.

Incidentally no mention has been made of the coverage of this unit. This depends on the builder who can spread the band as much as he likes depending on (a) the capacity of VC1A, B, C, and (b) the values of CI, C5, and C9. The padding capacitor used in the prototype enabled the receiver to tune the band over about 60 degrees which is quite adequate.

The BFO may now be switched on. A VTVM rf probe at C22 will indicate whether the stage is oscillating. With the receiver tuned in to a signal generator at 1820 kHz, set TC5 to mid capacity and adjust L6 until a good beatnote is heard. Set it to zero beat. This beat should tune from high pitch through zero beat to high pitch. Check that removing the signal removes the beat as it is quite possible that the 4th harmonic of the BFO itself may be tuned if the IF frequency was not set below 450 kHz. The harmonic will still be heard below the amateur band with the correct IF frequency.

Unfortunately, there are so few SSB stations working on the band that it has not been possible to establish with certainty that the level of injection is optimum. With the coupling to T3 base there is plenty of injection available. More or less can be had by adjusting C22. If trouble does arise, C22 could be connected to T4 base or into its collector. These options are simple to experiment with but can only be tried with a regular and reliable SSB signal. This is left to the constructor.

There is only a slight tendency for the BFO to drift in the first few moments. The constructor may prefer to mount TC5 on the front panel as a BFO tuning control. As such it should have a value of about 10 pF. For the CW enthusiasts who like to vary the tone this is certainly a must.

Performance

Originally the rf transistor was an OC170. This came to grief and was replaced with an OC44 without other changes. No instability was noted during tune up so, if available, the OC44 is recommended.

As for performance it compares favorably with an FRDX400 on sensitivity. The latter is better (and I should hope so as it costs a lot more), but not to the extent that I could not work anyone that anyone else was working. Selectivity is adequate for the present degree of activity on the band. For mobile working an external speaker is used as the small inbuilt speaker is a bit "hissy" and doesn't combat noise as well. Stability is very good; even dropping it a small height does not detune a signal.

To conclude, it has proved to be reliable, effective, simple to build, rugged and easy to get going. I couldn't see myself without one. ■

Tubes Are Not Dead!

by
Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

Not very long ago, there appeared in a *73* editorial a call for construction projects using tubes rather than transistors. The reason given was that many of our old time constructors don't really understand transistors that well and have thereby let the art of construction die. I personally find myself caught in the middle. My interest is basically VHF, but I am a child of the '60s transition era, the period of time in which the electron tube gave way to the semiconductor. I am also a professional TV service technician by profession, so I was forced to learn both art forms, tube and transistor, to survive in my industry. Therefore, while these days I tend to build using transistors, FETs, ICs, etc., I still do quite a bit of work with electron tubes, if only to eat!

When I entered amateur radio back in '59, I was just out of high school with little "bread" to spend on setting up an amateur radio station. I did have a good friend named Sol Rosenthal WA2MSX who was one of those "old school" radio technicians and was never too busy in his store to find the time to stimulate the ideas of this "youngster" — and answer the many questions that my mind would bring forth. "Jommie's" radio store was a veritable gold mine of old radios and TV sets, many of the former dating back to the '20s. So little "Billy," from about age 10 on, spent all his after school hours

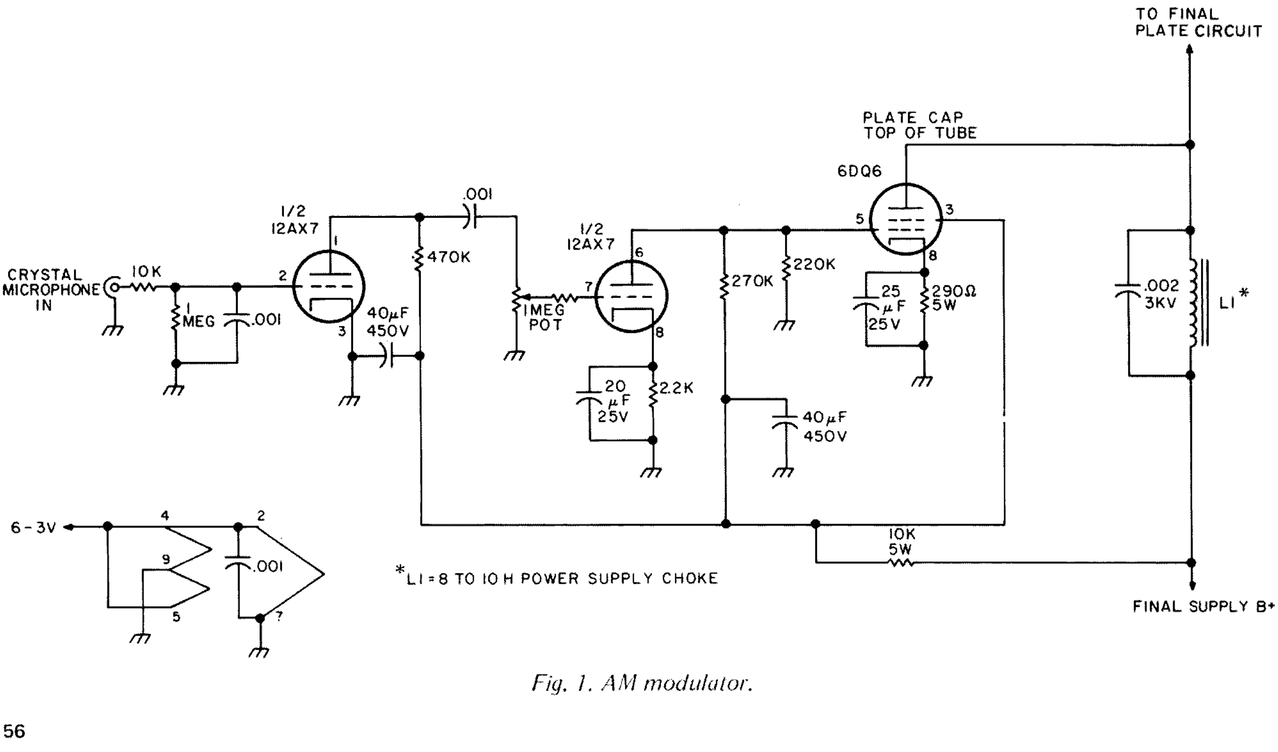

Fig. 1. AM modulator.

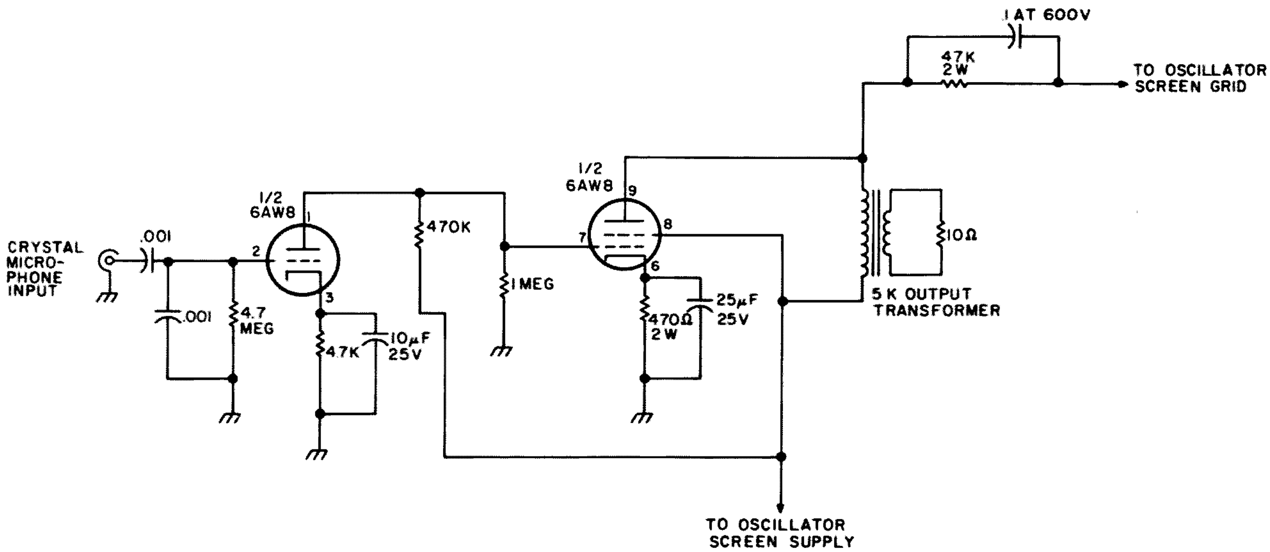

Fig. 2. FM modulator.

"hanging around" this fantastic learning spot, being educated in the true tradition of electronic repair. I was one of the lucky ones, for I received the kind of electronic education that no school can ever hope to offer. I was taught "little tricks of the trade" that have benefited me in later life – the type of education for which I will be eternally grateful.

I built my very first transmitter under Jommie's tutelage, on the side portion of his "L" shaped front counter. It was far from state of the art for the time. With salvaged parts from an old Dumint TV set, circa 1952, it consisted of a 6AB4 oscillator multiplier driving a 6BQ6 final doubler. Modulation was of the AM controlled carrier screen grid variety, using a 6SL7 speech amplifier and a 6SN7 control tube. A power transformer, 6AX5 rectifier, choke and a couple of filter caps made up the rest.

Oh, I forgot to mention, this was a VHF transmitter for six meters and amazingly enough it actually worked! Loading into a "V Beam" TV antenna through 150 feet of twinlead, it reached Orlando, Florida on its first contact – *my* very first contact!

Since that time, I have continued to build whenever the bug hits me. Of late it tends to be in the realm of solid state, but when the call went out for tube type projects, I dug back through my files to see what I could come up with that would not only fill the bill but perhaps be an incentive to help repopulate six meters, a band that is all but deserted these days. What you see here is a basic design that Larry Levy WA2INM and I came up with back around 1964 or 1965. It can be built with a number of different inexpensive tubes of the type commonly found in older tube-type TV sets, and in fact the entire transmitter less chassis can be salvaged from an old TV receiver. Just add your own enclosure, any fancy metering circuits you might desire, and package as you like. The only necessity is to follow good VHF construction technique, i.e., keep all leads as short as possible and bypass everything to ground with .001 disc ceramic capacitors. If you want to make a little larger investment, substituting a type 2E26 or 6146 for the TV sweep tube in the final will provide higher efficiency and greater power output for a given power input level. Depending upon supply voltage and final amplifier tube used, the transmitter can run up to 50 Watts power input AM or 65 Watts on FM or CW. AM modulation is accomplished by use of a beam power tetrode connected as a choke-coupled heising modulator, and FM by re-connecting this modulator to screen-grid modulate the 8 MHz oscillator tube (crude but effective; this is a low cost project) and keying the final amplifier cathode for CW. It's truly a "gut-level" transmitter with few frills.

A type 6BA6 tetrode functions as an electron coupled oscillator at 8 MHz, with the plate circuit left broadly tuned through use of a 2.5 MHz choke coil. A type 6AU6 will function equally well in this stage. The frequency multiplier is a type 6AQ5, though a 6CL6 will work better, and a 6BQ5 or 6CZ5 would also function quite admirably. The latter tube types necessitate a 9 pin tube socket and an RCA tube manual to determine pin connection. This stage is a x3 multiplier to the area around 25 MHz. In turn, the 25 MHz energy is coupled to the final amplifier tube of your choice, in this case a rather inexpensive type 6DQ6B hori-

Loading into a "V Beam" TV antenna through 150 feet of twinlead, it reached Orlando, Florida on its first contact – *my* very first contact!

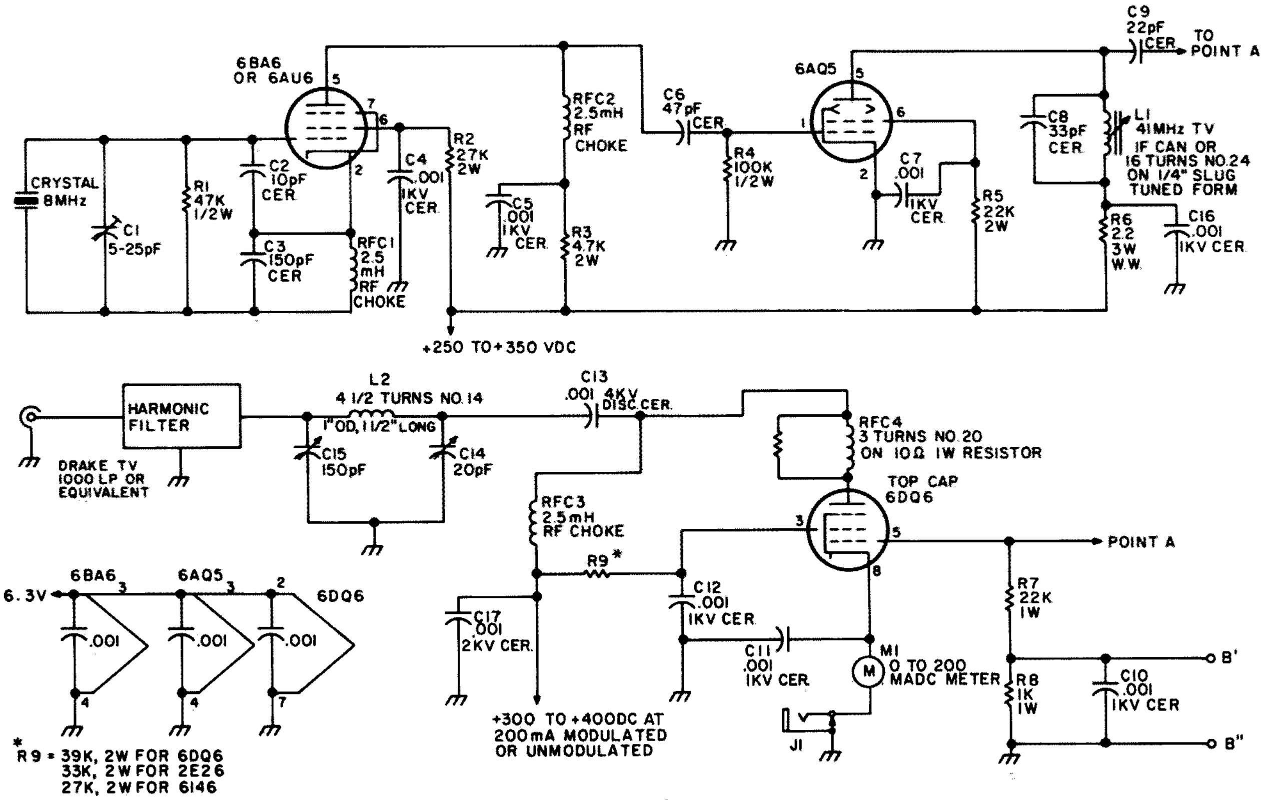

Fig. 3. Basic rf section.

zontal sweep tube. The plate circuit of the final is tuned to 50 MHz and pi-net coupled to the antenna terminals. Since the final amplifier acts as a frequency multiplier, it is quite rich in harmonic output and should not be connected directly to the antenna. A built-in Drake TV-200-LP filter works wonders here and makes it about as clean as a straight-through final running without the filter. The rf section is simple, neat and requires no neutralization. In fact, if you can get the final amplifier to self-oscillate, you had better tear the whole damn thing apart and start with a new layout. It's that stable. As to meter readings, with 275 volts applied to the driver and oscillator and about 400 volts to the final, you should run around 3 mA final grid current and 100 to 110 mA final plate current (when tuned into a 50 Ohm load). The easiest way to tune it up is peak the oscillator and multiplier for maximum grid current, then use an swr bridge in the antenna line and tune for maximum forward power. If it's working OK, maximum power output should appear at a minimum dip in plate current of the final.

For CW operation, just insert a key, flick the T-R switch to transmit and go CW to your heart's content. Since the oscillator and multiplier are running all the time, there is no chirp, and if your power supply is clean, the note will be clean and sharp.

For AM, just insert the modulator module in series with the plate supply voltage to the final, tune as noted (except keep plate current of the final below 100 mA), adjust the gain control on the modulator until the plate current needle starts to kick slightly on voice peaks, and *voila* good AM.

FM requires a bit more attention, but not too much more. The FM modulator takes the place of the screen grid resistor in the oscillator. Remove the screen resistor and insert the FM modulator module in its stead. There is no gain control on the FM modulator, but it does require close-talking the mike. Experience has proven that an extra preamp stage here leads to over-deviation. We found that 3" from the mike usually gives 5 to 6 kHz deviation, and quality is good. A frequency warping capacitor across the crystal sockets is used to zap yourself onto channel.

While many of you who are advanced in the art of design and construction may be cringing by the time you finish reading this, the others who are looking for a cheap, simple and utilitarian multi-mode transmitter for six meters may well find that what has been described here meets their needs. Best of all, if you can build at all, it will probably work well the first time you tune it up. Maybe tubes are dead, but they're far from buried. ■

Put a Pin Hole in Your Cadillac's Roof

73 Magazine Staff

Most amateurs who use 2 meters would prefer to have a ¼λ whip mounted directly in the center of the roof of their car for mobile use. Such an antenna is economical, provides a good omni-directional pattern, and usually is at least as efficient or more efficient than gain-type antennas mounted on lower positions of the car body. It also makes for a very neat looking installation. The big drawback of the mounting of such an antenna is the "hole in the car roof" problem. Commercial antennas require large holes or even multiple holes. Some methods have been described for the construction of home brew antennas requiring only a ¼" hole in the car roof. But WB2QVW has come up with an idea for mounting a whip on a car roof which literally requires only a "pin-hole" to be made in the car roof – a single hole of 1/8" diameter or even less. A mounting is used which allows the whip to be removed when the car goes through the car wash or for replacement purposes. A second alternative mounting is also described which does not allow the whip to be removed except from the inside of a vehicle. This type of mounting might be applicable to a vehicle which has a non-padded roof interior such as some recreational vehicles.

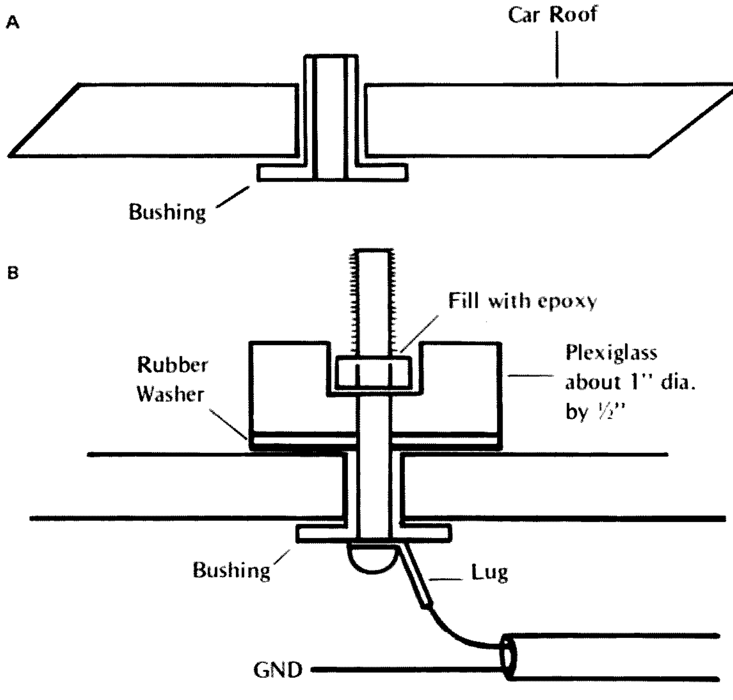

Fig. 1. The heart of the antenna mount is a fiber or nylon shoulder bushing (a). The complete assembly is shown in (b).

The electrical reason ¼λ whips can be mounted on a car roof with such small holes is that the base of the whip presents a low impedance, low voltage point so that elaborate insulation is not needed at the base of the antenna. Such mountings would probably not be suitable for ½λ antennas

which present a high impedance at their base. With a ¼λ whip and a 50 Watt output signal with a reasonable swr, the rf voltage at the base of the whip to ground should be no more than 5-75 volts. Mechanically, the simpler and smaller the antenna mount, generally the weaker it will be. Unless one lives in an area with extreme snow and ice conditions, however, the occasional replacement of the whip portion of an antenna may be a small price to pay versus putting up to a 7/8" hole in the roof of a car for a heavy duty commercial mount.

The first type of mounting is shown in Fig. 1. The heart of this mount is a thin, long plated steel bolt as shown in Fig. 1(a). A #4 (.115") bolt is probably the thinnest one would want to use although a still smaller #2 could also be tried. One may have difficulty obtaining such a bolt (1½" to 2" long) at the local hardware store; another alternative would be suitable size machine screw stock, which usually comes in one foot lengths, cut to any desired size. The bolt is inserted in a nylon spacing bushing which insulates it from the roof. An alternative is the use of a shoulder washer inside the car roof and a short fiber spacer for insulation as the bolt goes through the roof. Still another alternative is to "build" a nylon spacing bushing up from a fiber spacer and a flat fiber washer whose inside diameter matches the outside diameter of the fiber spacer. A look at the hardware assortment in a store should provide other possibilities also. Either fiber, nylon or teflon spacers/washers are suitable.

A solder terminal is used under the bolt head to provide a connection to the antenna. Another solder terminal may be used to pick up a ground point by inserting it next to the car body. Outside on the roof, a circular or cone-shaped block of plexiglass or similar material (even wood) is used to build up the antenna base. A nut in a recessed hole on top of the block secures the bolt and the recess is then filled in with epoxy. The antenna proper is secured to the stud which remains above the block. The antenna proper can consist of almost any light-weight rod material one has on hand, but a very suitable material is brazing rod. It comes in 19-20" lengths and about 1/16" diameter. It should be available at any welding supply store, or even any garage which does body repair work will have it. The rod can be soldered to a few nuts which have also been soldered together and screwed on the stud. If one has the facilities, one could machine a small part to mate the rod and stud. Still another possibility is to use a banana socket to fit over the stud and solder the rod to the socket. As a final touch, a small cone-shaped plastic insulator as found on an alligator clip should be slipped over the whip to cover the stud to provide a rain cover.

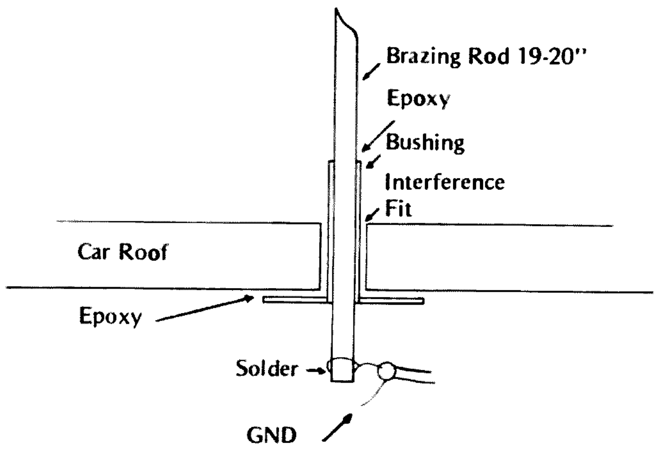

Fig. 2. The super simple mount. Total antenna cost is about 25 cents!

The whole assembly as described may sound a bit simple, but it will work very effectively and if constructed with care can look very professional. All this for a cost outlay of less than $1.00!

If one really wants to have a simple but equally effective 2 meter antenna at a total cost outlay of about 25 cents, take a look at Fig. 2. This simple antenna makes use of a brazing rod and a nylon or fiber spacer bushing (or any of the substitute assemblies previously mentioned). The hole made in the car roof need only be slightly larger than the brazing rod. As shown in the diagram, epoxy is used to secure the mounting to the car roof and the antenna rod to the bushing. This extremely simple mounting does not provide any means to remove the antenna. But for many recreational or sports vehicles which don't go through a car wash, this is not a problem. Such vehicles usually have unpadded interiors on the roof and if something should happen to the antenna, it is a simple manner to put in a new antenna at a replacement cost of 25 cents! It is assumed that one can pick up a ground connection near the antenna — by a bracing support or dome light — without having to make a hole that penetrates the car roof.

Trimming up of the antenna on a specific operating frequency consists simply of putting an swr meter in the transmission line and cutting down the full length whip in about 1/8" steps. A point will be found where the swr drops sharply to about 1.5 to 1 or less. Rather than cutting further one can make a final trim by forming a small U bend at the tip of the antenna. The value of further trimming once one gets the swr down to the 1.3 to 1.5 range is of moot value with the usual 5-10 foot transmission line. ■

The whole assembly as described may sound a bit simple, but it will work very effectively and if constructed with care can look very professional. All this for a cost outlay of less than $1.00!

A COMPREHENSIVE DESCRIPTION OF THE MICRO - SPHERE 200 SYSTEM

The Micro-Sphere 200 Series computer is the most ADVANCED, low-cost computer SYSTEM available today. Together with a TV and up to three cassette recorders you can have big computer performance at a rock bottom price.

The system features a 6800 type micro-computer with 4000 characters (4K Bytes) of internal Random Access Memory (RAM) Storage. The memory is easily expandable to 8000 total characters with the addition of an optional second 4K of RAM, with even more memory to be made available shortly. The 4K bytes of memory is equivalent to 6-8 pages of close typewritten material.

Access into the Micro-Sphere is achieved by the keyboard or from cassette recorders. The computer can display information on a standard TV screen (optionally supplied) or store information on a cassette recorder.

The keyboard uses highly reliable keyswitches to insure user satisfaction. It is full alpha-numeric including an integrated numeric key pad. The cassette interface uses the "Kansas City" standard which means that you can use even the least expensive cassette recorders with your system satisfactorily though we suggest that you do use high quality tapes with your system.

You may use your own TV without modification as the system display device, or you may purchase one from Sphere.

The power requirement is a single 110 volt AC outlet. The unit uses less power than an ordinary 100 watt light bulb. All fuses, jacks, switches, and interface signals are provided on an easy-access panel at the rear of the cabinet.

The Micro-Sphere is supplied with a built-in loading program from cassette, which is in one of the several standard or optional Read Only Memory (ROM) Integrated Circuits (IC).

ROM IC's are pre-programmed with specific non-eraseable information. This feature greatly reduces program loading time and inconvenience, ROM's also save valuable RAM storage. RAM's lose all stored memory whenever the computer power is turned off, while ROMs retain all programs indefinitely.

The Micro-Sphere is unique in that 16,384 different dots on your TV screen can form any number of pictures or designs which you have instructed your computer to display. These images can be changed by the computer program at a rate that appears as real-life movement, such as aircraft flight simulation, "walk-through" inspection of architectual mock-ups, time-lapse stock market graphic analysis, or even computer generated art forms, or space flight simulation where you can guide your spacecraft to the moon, planets or the universe.

You can experience the thrill of rolls, dives, loops, near-collisions and other types of aerial maneuvers to out wit the Red Baron in your Sopwith Camel and then the excitement of a victorious landing as you crash at the end of the approaching runway.

This same 128 row by 128 column dot matrix can form an alpha-numeric display of up to 16 lines by 21 characters. An optional graphics input device (Mouse) digitizes hand movements when moved about on a flat surface. The "Mouse" has a window and crosshairs, so it may be used for the accurate entry of maps or other graphic data.

The mouse may also be used in the place of a joy stick for flight simulation or to enter hand movements for ping-pong or other games of skill.

The Sphere Cassette Operating System (SCOS) is supplied on tape and provides Assembler, Edit, and Debugging functions to the computer when read in to RAM from the Cassette. Sub-routines for floating point and trig functions ore included in the SCOS cassette and may also be purchased as an option in ROM. Sub-routines are included in SCOS which provide all necessary alpha-numeric character generation for your TV using approximately 400 bytes of RAM. An optional character generator ROM can be purchased to reduce RAM usage to 50 bytes. SCOS also supports file handling.

If the second 4K of RAM is purchased the macro facility of the assembler is then available as an extended aid to help you in the development of your own programs. The second 4K of RAM will also allow you to read in extended Business Basic from cassette.

This basic provides 16 digits of decimal accuracy and extensions for business use. This Business Basic can make use of the Floating Point and Trig Package in RAM or ROM to expand its capabilities into the engineering field. The Business Basic and Trig Packages are available in ROM, which leaves all of the RAM storage available for applications written in the Basic Language. This is a concept for which you may pay $9,000 to get from an IBM 5100 computer.

Sphere Corp. has included in the basic price of the Micro-Sphere 200 the Monte Carlo games package on cassette, which allows you to play blackjack, roulette, and other games just for fun.

One Cassette recorder is sufficient to do everything by simply changing tapes. Multiple file handling such as inventory control, pay roll, and general ledger processing etc. will be more convenient if two or even three cassette recorders are used. For example tape #1 may contain the last year-to-date accumulation file, tape #2 may contain the present pay period account, while tape #3 is used to combine tapes #1 and #2 into a new year-to-date accumulation master file. The second and third Cassette Interface options are available for those who require them.

In the near future, Sphere will release a Programmable Input/Output Controller for use with printers, disks, and other input/output devices.

The attractive two-tone case is made of mar-resistant high impact plastic designed to fit any modern decor. Additional strength and protection to components is provided by an internal metal chassis.

The unit is designed to operate in a normal home or office environment without any extra care. The Micro-Sphere is the product of many years of experience in the micro-computer field, providing a tremendous amount of power and capability in the smallest space-it requires only a small desk with space left over, and it comes fully assembled and tested--ready to use.

LIMITED WARRANTY — This unit is warranted to be in operating condition as described upon arrival.
OPTIONAL FULL WARRANTY — For additional 10 percent of purchase price. For a period of one year following delivery of the Micro-Sphere 200, you may return the unit to Sphere for repairs or replacement if any component is found to be defective or inoperative. This warranty can be renewed each year for 5 years.
WHAT IS NOT COVERED — Power cord, fuses, damage incurred by shipping abuse, natural disaster, war or accident. Shipping, handling, postage and insurance are 2 percent in addition to purchase price.

PRICES FOR MICRO-SPHERE 200 WITH OPTIONS

No.	Description	Price/Each	Total
200	MICRO-SPHERE 200 - SYSTEM PRICE INCLUDES "A" ITEMS BELOW	$ 860.00	$ 860.00
	"A" ITEMS: 6800 type Micro-Processor unit		
	4K of Memory (RAM)		
	Cassette Loading System (ROM)		
	Sphere Cassette Operating System (SCOS) Cassette — 1 time license fee @ $137.50		
	Includes Floating Point and Trig Package — Cassette copy @ 12.50	$150.00	Incl.
	Monte Carlo Games Package (Cassette)	$10.00	Incl.
	First Cassette Interface		
	128 by 128 B&W Dot Matrix Graphics Display		
	Alpha-Numeric Keyboard		
	Attractive Mar-Resistant Plastic Case		
	Operators Manual		
	OPTIONS AVAILABLE THROUGH FACTORY INSTALLATION. * To install options after purchase is $35.00 per shipment to our plant.		
	"B" ITEMS: Second 4K of memory (RAM)	$180.00	$180.00
	Character Generator (ROM)	$25.00	$25.00
	"C" ITEMS: Second Cassette Interface	$50.00	$50.00
	Extended Business Basic (ROM) Includes Business Basic Manual	$400.00	$400.00
	Floating point & Trig package (ROM)	$130.00	$130.00
	Third Cassette Interface	$50.00	$50.00
	OPTIONS FOR PURCHASE NOT NEEDING FACTORY INSTALLATION.		
	Extended Business Basic on Cassette (Requires 2nd 4K of RAM and Character Generator in ROM.) Includes Business Basic Manual Floating Point & Trig Package	$100.00	$100.00
	9" TV for use with Micro-Sphere 200	$150.00	$150.00
	"Mouse" Graphics Input Device (Available in May 1976) 2 ea.	$150.00	$150.00
	Operators Manual (SCOS)	$10.00	$10.00
	Business Basic Manual	$10.00	$10.00
	Maintenance Manual	$40.00	$40.00
	Empty Cassette Tapes 3 for	$10.00	$10.00
200A	INCLUDES MICRO-SPHERE 200 PLUS ALL OF "A" ITEMS ABOVE REGULAR $860.00	$860.00	$860.00
200B	INCLUDES MICRO-SPHERE 200 PLUS ALL OF "A" & "B" ITEMS ABOVE REGULAR $1215.00	$1215.00	$1215.00
200C	INCLUDES MICRO-SPHERE 200 PLUS ALL OF "A" & "B" & "C" ITEMS ABOVE REGULAR $1645.00 - EVERYTHING IS IN ROM !!	$1645.00	$1645.00

ALL UNITS ARE COMPLETELY ASSEMBLED AND READY TO USE!!

uP

That's u as in micro, a P as in processor. The world of uP is changing too fast to keep in touch. Like the first really big uP chip was the Intel 8080, which came out at around $295, as I recall, and was a bargain at that price. Bill Godbout called the other day to lay our ears back with his latest deal . . . an 8080 (prime chips, he says, not seconds or rejects . . . prime), eight of the 2102 RAM memories for 1K bytes of RAM, plus a 5204 5K byte PROM . . . the works for $65. Lordy!

That should get the rest of the experimenters off their duffs and busy putting uPs together. What can you do with 4K PROM and 1K RAM plus a uP chip? Well, you sure can run a repeater to a fare-thee-well, have an extremely sophisticated keyer with all sorts of memory, and even play a lot of the simpler computer games. The fact is you have a simple computer which can be expanded with more RAM memory and some interfaces to work with slow scan, with teletype, cassette recorders, paper tape gear, etc. The only fly in the ointment is that you will have to accept that you are an experimenter and you won't for the time being find much in the way of assistance from friends or magazine articles.

One other thing . . . you are going to have to start boning up on how to program uP systems. With any luck we'll start running some articles in *73* on this. You might even be the one to write 'em.

THE GREAT COMPUTER PERIL

All is not skittles and scones (whatever those things are) when you put a computer kit together. Sure, you end up with a gadget that is more fun than a barrel of monkeys (to coin a phrase . . . say, have you ever tried out a barrel of monkeys? . . . or even one monkey? My folks had a monkey when I was younger and monkey-owning has its joys and sorrows).

Once you actually get your computer working and doing things (Herculean task, some say), it is all too easy to forget some of the goals you maybe had in mind for mating it with ham gear and succumb to the fun of putting in some game programs. The next step is all but inevitable . . . bragging to your family about it. Once you've opened your mouth you've essentially lost your computer, for you will have one heck of a job getting them to allot you some time with it . . . particularly if you have any kids between seven and forty-seven hanging around.

Look at the bright side as you are putting together your second computer. You have to admit that this is the first time you've built anything which was of interest to the family . . . and that your image has subtly altered from being just a weirdo who spends a lot of time soldering useless ham gear together and then presents his back to his family while he uses it. You may even begin to detect some slight signs of respect, however camouflaged. If you hang around behind corners you may hear your kids bragging to their friends about your wizardry. Oh, they'll still put you down at every opportunity if they think you can hear, but you watch and see.

Well, the prices on computer kits are coming down, so maybe it's a good idea to shop around and get a second one. Unless you have the good fortune to work in a chip factory, you'll probably do much better to go the kit route. The kit people are buying chips in large lots and the prices are enough lower so you'll have a tough time matching them.

YES, BUT WHICH KIT?

Hopefully we will begin to get some articles discussing the pros and cons of the various computer kits available. For many applications, there is less than a significant difference between systems based on the different microprocessor chips.

MITS got in there first and this has a lot of advantages for the home builder. A great deal of competition has built up aimed at supplying boards and peripherals for the Altair system. Thus the bus structure of the Altair has become an accepted bus standard. MITS further locked much of the microprocessor industry into their bus by bringing out their new 6800 based board using the same bus and plug compatible with the Altair 8800 system.

What's a bus? It's the wiring between all of the components of the computer. Rather than having each printed circuit board of the system plugged into the other boards as we do with most electronic systems, all of the boards plug into a common set of wires and the switching of signals is done with programming rather than real switches. It's a lot easier that way and saves on hardware as well as cabling.

Many firms are now providing kits of parts for boards which will work with the Altair system . . . memories, interfaces, clocks, etc. If you want to use a teletype machine with your computer you have to have a circuit to take the information from the bus and send it to the teletype. It has to ignore bus data intended for going in or out of memory, in or out of tape recorders, television typewriters, etc. Your interface boards only pass that information along addressed to a specific destination . . . such as a teletype . . . and they convert the information into the form needed for the unit being served. In the case of a teletype it would convert the bus info into a 20 mA series of pulses (or 60 mA if you are using a slower and older machine). For a cassette recorder it would convert the info to a series of frequency shift tones. Okay?

In selecting the kit of your choice you have a lot of factors to consider. Since all of them are pretty good, you won't really lose by throwing a dart . . . but it is possible to get a good enough grasp on what is happening to make an educated selection.

The older kits have the advantage of being much better supported with info on problems and programs. As you get more involved with computers you will begin to understand the overwhelming importance of programming. This is a new concept to most of us and we are inclined to give it short shrift. Don't. There is an awful lot to be said for a lot of software support for a system.

On the other side of the coin, newer kits are generally able to work a lot faster and have more sophisticated abilities. Progress has been extremely rapid in the microprocessor chip design field and there are substantial differences between older chips and the new ones. A dilemma. The newer chips are better, but we are going to have to wait a while before we can get much in programming for them.

One comforting aspect to this is that the above dilemma is not really of significant importance to stop you. Practically speaking, most of the expense of a computer system is in the interfaces, memories and peripherals . . . and there is no sign that we are going to have any breakthroughs in these which will obsolete your systems. You can start out with an 8008 based system and add memory, teletype, TVT, and use the wealth of data available for this older system . . . plus all the programs . . . and then change the CPU to a 6800 system and keep everything but the microprocessor itself.

One fact you are going to have to face . . . hard fact . . . programming is not going to be very meaningful to you until you have some hardware to get your hands on and learn by doing. Oh, we can explain the fundamentals of programming in articles, and then give you lots of clever ideas for improving your programming skills, but like Morse Code, you are on your own when it comes to really learning how to program.

Once you start to get the hang of programming you'll have a ball with it. With some of the systems, you can program in just about anything that you would normally expect would require switches to accomplish . . . converting from ASCII to Morse Code . . . at whatever speed you want . . . or from Morse to ASCII . . . or to Baudot. You can route the output to your rig, a repeater, lights, a teletype, a cassette recorder, door chimes . . . anything you want. You can program music generation . . . a whole bunch of people are getting off on computer music these days. You can generate

What's a Computer?

Many experimenters are reticent to purchase and build a microcomputer system, even though complete systems can now be purchased for less than $100. This hesitancy on the part of interested experimenters can in most cases be attributed to several factors:

1. Temporary depletion of pocket cash.
2. Lack of knowledge of computer fundamentals.
3. Lack of personal confidence in being able to handle the technology required.

I have prepared a series of articles addressing problem areas 2 and 3 (problem 1 is only temporary!) by giving the experimenter a fundamental overview of computer principles. The various components of fundamental computer systems will be discussed, computer terminology will be explained, and fundamental, inexpensive breadboard circuits and experiments will be given in order to teach the rudiments of computer technology. The simple circuits and related experiments will give the experimenter the experience and confidence needed to build and debug computer circuitry.

The average experimenter with a basic knowledge of electronics who studies these articles and performs the experiments given should be capable of building and using his own microcomputer system.

What Is a Computer?

A computer is a device which accepts information, applies some prescribed process to that information, and supplies the results.[1] This definition can be applied to large classes of devices. For example:

1. A series of gears, shafts, axles, cables, etc., such as a speedometer, takes rotation of axle (accepts information), converts the information to usable form (applies prescribed process), gives reading of speed on dial (supplies results).

2. A frequency counter takes input pulses (accepts information), counts them (applies prescribed process-counting), displays frequency on an indicator (supplies results).

3. An amplifier takes a small voltage (accepts information), amplifies it (applies prescribed process-amplification), gives larger voltage as output (supplies results).

These three devices are all examples of "common" computers.

A "computer" is not always recognized as a "computer," and a "computer" is not always called a "computer." The term "computer" is a broad term and may be applied to common everyday devices. Computers need not be electronic, but may be mechanical, hydraulic, pneumatic, or perhaps biological.

What is a Digital Computer?

Computers are divided into two common classes: analog computers and digital computers. Both classes of computers are the same in that they accept information, apply a process to that information, and deliver results; however, they differ in the types of information which they can handle.

An analog computer processes information within a continuous range or within continuous ranges. Using the amplifier as an example, consider a simple device which will deliver a gain of precisely 100 to voltages in the range of .03 V to .08 V. In this amplifier an input of .03 V will give 3 volts out. An input of .039927 V will give 3.9927 volts out. This simple analog computer will operate with *any* voltage within its specified range. Furthermore, *all* values of voltage within the range of the device will be processed. The range of the information that the analog computer will handle is continuous – there are no gaps within the range.

A digital computer can process only discrete values (for example, in the range 1-5,

Fig. 1. Fundamental computer.

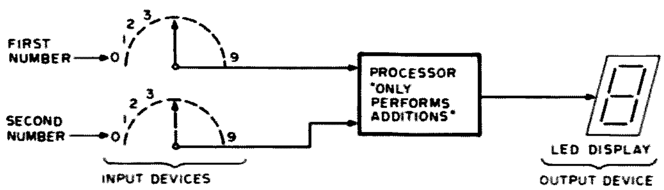

Fig. 2. Simple "addition only" computer.

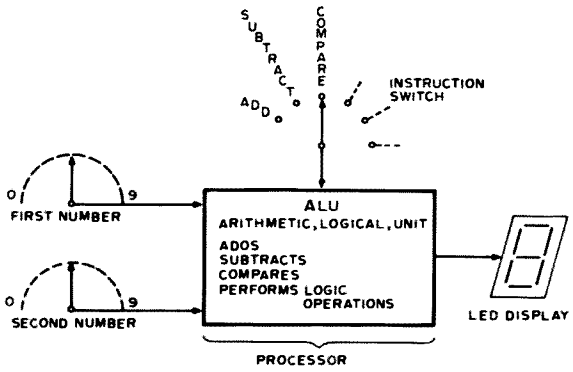

Fig. 3. Simple computer using ALU.

the numbers 1, 2, 3, 4, 5 are discrete values). The digital computer is not capable of handling continuous information. The reason for this is simple. The digital computer uses a series of "on-off" conditions to store information. The number "one" might be represented by an "on," while the number "zero" might be represented by an "off." But what about numbers such as .5? Can you have half of an "on" or half of an "off"? Certainly not very conveniently. Of course we could change our definition and let .5 be represented by an "on," but then how do you represent .55, .51, and so on? The point is that a digital computer can only handle discrete numbers, regardless of how we define those numbers. It cannot handle *all* numbers in a given range.

The frequency counter is an example of a digital computer. It accepts discrete pulses, counts them, and displays the results. In a given one second interval it cannot count 1/2, or 1/3, or .40497 of a pulse. It can count only discrete pulses.

What are the Components of a Digital Computer?

The typical digital computer may have numerous components with a rat's nest of interconnections; however, a fundamental digital computer requires only three pieces: an input device, a processor and an output device (Fig. 1).

The input device may be as complex as a graphics input terminal or it may be as simple as a single switch. The output device may be as complex as a video display or it could be a single small indicator. The processor could be very sophisticated, or it could be simple logic used to detect the simultaneous presence of switch closures.

As an example, consider a simple computer which has the sole function of adding two numbers in the range 0 to 9 together and displaying the output on an LED indicator. The block diagram of this simple computer is shown in Fig. 2.

This simple computer is a fixed function computer and can do only one function – add. The limitations of this computer should be apparent. It has a small range (0-9), cannot perform other arithmetic functions, and cannot compare two numbers for equality.

We could expand the capabilities of our processor by exchanging the simple "addition box" for an ALU (arithmetic, logical unit). This ALU type of processor is a readily available unit and offers additional capabilities such as subtraction, comparison of two numbers for equality, and logical operations such as "and" and "or." The simple configuration has now been expanded to that in Fig. 3 by the addition of an extra switch, an "instruction" switch, and by using an ALU for the processor. By varying the position of this switch, the various "instructions" could be selected. We could perform any of the allowable operations on our two "input" numbers and have the results displayed on the LED indicator. At this point, the fundamental computer has additional capabilities, but still does not have enough capability to be really practical. The ALU by itself can only process two independent numbers at any given time. It is not capable of simple steps such as adding a column of ten numbers, let alone complex problems involving many steps.

If our problem was to add a column of ten numbers, we could expand the fundamental computer still further by adding some device to store the column of ten numbers. The device could be connected to the processor in such a manner that the ten numbers would automatically be added. This storage device could be in the form of ten sets of switches, a tape recorder, a rotating magnetic disk, a series of magnetic cores or a series of electronic storage locations. A storage device in one of these classes is commonly called a memory. Note that a memory can be of several forms and is not limited to magnetic core or electronic storage. (Note: One of the earliest digital computers used a tank of liquid mercury as a delay-line memory.)

At the risk of appearing to go on and on forever, one last addition will be made to the fundamental computer system – an instruction memory. This instruction memory will serve to hold a series of steps for the processor and will give these instructions to the processor in sequence. A clock (in this example, part of the instruction memory) is used to generate pulses to step the instruction memory from one instruction to the next (Fig. 4). With this system we could command the processor to perform the following steps in sequence:

1. Add the first two numbers.
2. Add the last two numbers.
3. Compare the two sums.
4. Display the smallest sum.

Of course the sequence of commands could be endless. This simple computer system has a lot of versatility and could be very useful. (An example of this type of "programmable" computer is a programmable calculator.) The process of setting up the instructions for the computer is called *programming*. The computer as it follows the programmed instructions *executes* or *runs the program*.

A Real Life Computer

A real life computer does not differ much in logic or function from that shown in Fig. 4; however, the ALU is usually expanded to provide additional capabilities, and additional circuitry is usually provided to simplify input/output as well as to facilitate

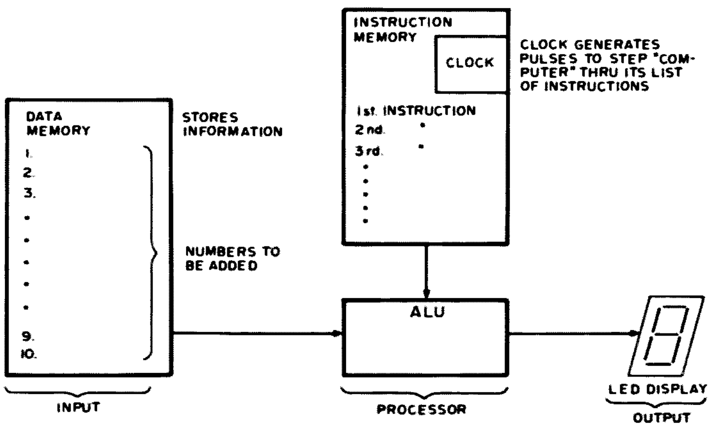

Fig. 4. Computer with memory.

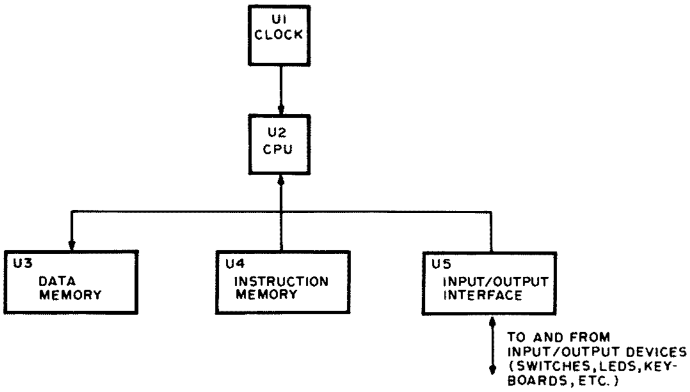

Fig. 5. "Real life" computer. U1 = 4201 clock chip; U2 = 4040 CPU chip; U3 = 4002 random access memory; U4 = 4308 read only memory; U5 = 4207 (4209, 4211) general purpose I/O.[2]

the flow of information and instructions within the system. While this last statement may sound like a "zinger," it is not, since a device called a "CPU chip" (a single integrated circuit) in most cases contains the additional circuitry as well as the arithmetic and logical functions. A CPU chip (Central Processor Unit) is a very unique and versatile device and is commonly called a "microprocessor." Fig. 5 shows a block diagram for a typical, fundamental microprocessor computer system. The five blocks shown correspond to 5 integrated circuits. This is a real life system. An Intel 4040 microprocessor system could be built using just 5 ICs.

How Do I Get Started?

It is not difficult to wire five integrated circuits together to form a microprocessor system. It is difficult, however, to make the plunge without first acquiring some important fundamental knowledge. By gathering this basic knowledge first, you can better utilize your microprocessor and you are in a better position to correct a problem should difficulties be encountered.

Fortunately, a large investment is not required in order to get into computers. For a nominal investment in a power supply, a breadboard, and a handful of very inexpensive ICs, the experimenter can build up simple computer-oriented circuits to experience firsthand just how things work. While simple circuits will not duplicate all of the functions of a microcomputer system, the experimenter will be able to perform arithmetic and logical operations as well as store and retrieve information with simple memories. If the experimenter is able to understand these basic concepts and is able to duplicate simple experiments, then he should be able to build and use a microcomputer system. Future articles will explain some of these simple circuits and experiments.

The Next Step

Man works with numbers in the decimal system, while computers work with numbers in the binary system. Future articles will discuss number systems, will explain how to do arithmetic in the binary system, and will give procedures to convert from one number system to another. Several experiments have been designed using an inexpensive ($3.95) ALU chip to illustrate binary arithmetic. Future articles will also discuss logic, memories and input/output. ■

I/O

from page 67

fantastic art forms by plugging into a color TV set . . . and there is a rapidly growing group of people working on computer art.

You can program your computer to compare any input against a desired data. You might tune in the Congressional Record on RTTY and set your system to check for certain key words such as Amateur Radio . . . and whenever this came up in the text your teletype would start printing.

Or perhaps you'd like to have your system switch your 2m receiver through all of the local repeaters constantly, checking for anyone sending a certain series of tones which would be your calling code. You get the picture.

CASSETTE I/O STANDARDS

One of the least expensive bulk memory systems so far available uses the garden variety cassette recorder. Those 4K and such memories in the computers are used to sort out and process data in the computer . . . the system still needs some place to store data for later use. The data may be programs to get the computer to play certain games, it might be names and addresses for a mailing list, book or record lists for an index, etc.

Eventually we will have other bulk memory systems which are reasonably low in cost. At present a floppy disk memory runs around $2000, which puts it rather in the expensive area for most home systems. A disk can hold around 250,000 bytes of memory and make it available within a few microseconds . . . good business if you are going to sort data or want quick access to random things.

Regular computer tape drives are not cheap . . . yet. They use half inch tape (usually), and cost $2000 or so, too. They can hold a lot more memory, but the time required for searching through the tape is much longer. There are some quarter inch tape cartridge systems in evolution which may be low in cost for home computers, but nothing is yet ready.

All of which brings us back to cassettes.

When I began to get an understanding of what was involved I looked to see what standards were being used for putting information on cassettes. I found, much to my horror, that there seemed to be as many standards as there were firms coming into the field. This would never do! We needed one standard for cassettes so that any program or memory cassette would work in any system regardless of manufacturer.

Since there was no one else to tackle the problem, I figured it might as well be me. I sent letters out to everyone in the industry that I knew about suggesting a meeting of everyone involved on neutral ground. I picked Kansas City because that was equally far away for everyone. I scheduled the meeting for November 7-8th.

The meeting came off right on schedule and just about everyone from the microprocessor industry turned out for it. At first the meeting got off to a very slow start and it looked as if no agreements would be possible, but (as I suspected) the spirit of cooperation won out and everyone finally got together and hammered out a standard which was agreeable to all.

The standard calls for two tones to be used, a mark tone at 2400 Hz eight cycles long for logic one and a space tone 1200 Hz and four cycles long for logic zero. A recorded character will consist of a space (start) bit, eight data bits, and two or more mark (stop) bits. The eight data bits are organized with the least significant bit first and ending with a parity bit, if used. All unused bits will be mark tones . . . e.g., the three unused bits when you are sending five level data. Mark tone will also be used in between characters as fill.

This system will give you about 47K bytes of data on a 30 minute cassette (one side of a C-60). If you use all four cassette tracks that would add up to almost 200,000 bytes. To put that in terms of an application, figure that you are putting names and addresses on the cassette. If you take 80 bytes for each name and address (which is what we use for the *73 Magazine* subscription records), this would permit you to have over 2000 names and addresses on a single cassette. That's a hefty amount of storage. If you are going to use an inexpensive recorder you would probably only put half that much on it since you would only use one track each way . . . but 1000 names isn't bad!

DO YOU REALLY WANT ASCII?

One of the questions I get a lot at hamfests has to do with when I think the FCC is going to okay ASCII for use on the ham bands. In due time I asked about this and got the news that there hadn't been a lot of worry about rushing ASCII because there had been very little demand for it to their knowledge.

It is the squeaking wheel that gets greased, to again coin a phrase. If you want to use ASCII on the bands, as what reasonable amateur wouldn't, you would do well to keep after the big candy store. Write them about it. Better, ask for "Special Temporary Authority" (STA) to try out ASCII and then get busy with it and pepper the FCC with reports on your fantastic results.

If we have to translate everything from ASCII to Baudot or Morse Code to send it we are hobbling ourselves as far as modern communications is concerned. ASCII is the standard and it should be permitted on the bands, so get busy.

The IC See-er

Having been a dedicated ham and/or electronic freak for upwards of forty years (I was born in 1920, so you figure it out), I feel that I can speak with some authority on the subject of home construction of electronic projects. Unlike an engineer pal of mine whose motto is, "Never build it if you can buy it," I have one which is, and has always been, "Never buy it if you can build it." I have a shop full of electronic residue to prove it – and some of it even works.

Until recently I thought that I had run into every form of frustration possible in the genre – that is, until I started (about six months ago) my love/hate relationship with the ubiquitous integrated circuit. It is my considered opinion that no invention in electronics since the galena crystal and cat's whisker (and I can remember them, so how's that for dating?) has caused as much fumble-fingered cussing and soldering iron-induced frustration as the IC. Well, since I have always wound up spending more time building the tool to do the job than on doing the job, here is a gadget that will cost you less than ten bucks to build (using all new parts), will cure all of the abovementioned evils and will take the hate out of love/hate.

Yeah, I know that there is an outfit that builds a better one, but this is for guys like me who wouldn't buy one even if we could afford the fifty bucks.

As you can see in Photo 2, I built it in a 7" x 7" x 2" aluminum chassis. The lens is one of a pair of condenser lenses from a long since defunct 4" x 5" Omega enlarger. These little tidbits are six and a quarter inches in diameter and weigh in at about two pounds apiece. I'm waiting for a seven inch plastic lens to arrive from Edmund Scientific, so I can build a new improved version and maybe sell Wayne another article.

Photo 1.

I think that it will be obvious from the explanatory photos (2, 3, 4) that a collar was fashioned (six inches in diameter by two inches deep) from scrap, medium hard aluminum, to hold the condenser lens in place in the chassis (after cutting a six inch diameter hole in same).

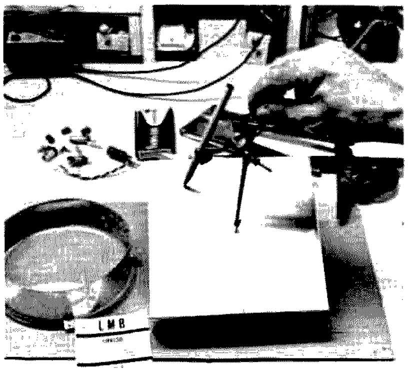

Photo 2.

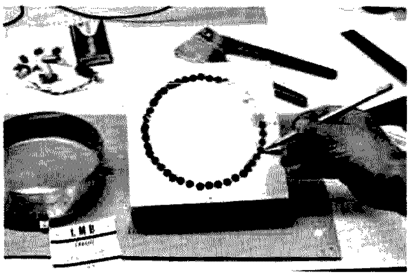

Photo 3.

Please take note (Photo 3) that I do not own a fly cutter large enough to cut a six inch circle, so I fell back on the old-fashioned method of drilling a series of small holes and chiseling away the metal between them. Since aluminum chassis are soft, it goes rather quickly, and the whole operation took me less than ten minutes using a drill

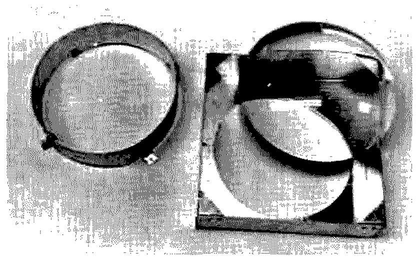

Photo 4.

press. If you have to use a hand drill it will pay you to center punch at proper intervals so that you will not mess up your nice new chassis. After you have the circle cut, a half round file will dress the rough edges easily. Before I forget, I split a piece of spaghetti tubing lengthwise and used it for an edge liner around the hole. A spot or two of glue and the pressure of the lens keeps it tight, and it makes a very professional looking finish.

I drilled holes in the sides at the point of balance and inserted three-sixteenth inch bolts and nuts for the side supports. By adding wing nuts and lock washers, I created

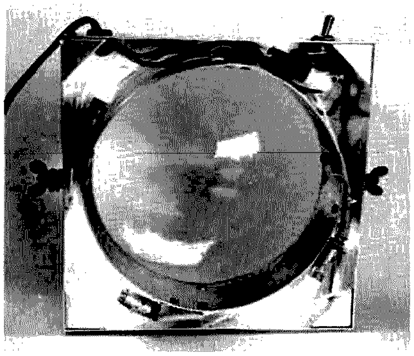

Photo 5.

an easily adjustable mount. Two pieces of 1/8" x 1¼" x 7" aluminum from an old panel were used for side supports, and I bolted them to a scrap plate of 5/32" x 8" x 8" metal that has been kicking around the shop for years. As you might suspect (and as my XYL will tell anyone who will listen), I never throw anything away, and this base is the living proof that it pays.

I must admit both that I should live in a barn and that my wife is a living, breathing saint (direct from the Old Testament) for putting up with me. Actually, the mounting of this gadget can be done any number of ways and this was just the easiest and quickest, considering the weight of the lens. Besides, I was in a hurry to finish as I had a project waiting to be soldered and I wanted to give the IC-See-er a workout.

Now for the novel lighting arrangement (Photo 5). As you can see, there are four pilot light sockets fastened at equally spaced intervals around the outside of the retaining ring collar. If you decide to go my route on this, I want to give you a word of caution right now!

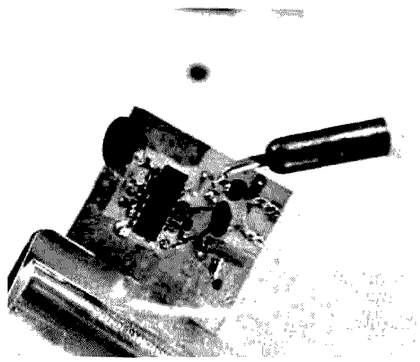

Photo 6.

Make damn sure that the sockets are well insulated from each other and from the metal collar that they are mounted on, 'cause what I did was to wire them in series and hook them across the 115 V ac line with a switch to turn them off and on. The bulbs are Tung-Sol #T313, 28 volt, bayonet base pilot lights. Twenty-eight times four equals 112 volts, and hooked across 115-120 this gives a not brilliant but very pleasant and quite adequate light for close-up work.

An additional bonus is the high-priced PC board vise (always give them a little extra for their money). It will be obvious that this added luxury feature is the really expensive item of the project, since chromed two inch

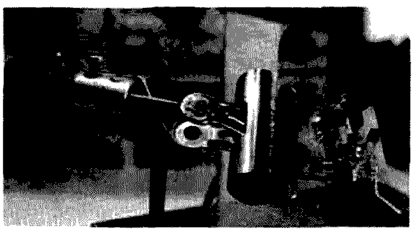

Photo 7.

Photo 8.

paper clamps are selling in our inflated economy for the munificent price of twenty-seven cents each. I splurged and bought four, so that I would have extras for a vise to hold larger PC boards. The rest of the stand is made, as is shown in Photos 7 and 8, from odds and ends of ¼" shafting and old shaft collars, plus some assorted scraps of aluminum and radio hardware.

It took me about two hours to build this little gadget and, quite honestly, every ham/experimenter who has been in the lab has tried to steal the damn thing right off of the bench, with me watching yet. Suffice to say I would not part with it for love or money.

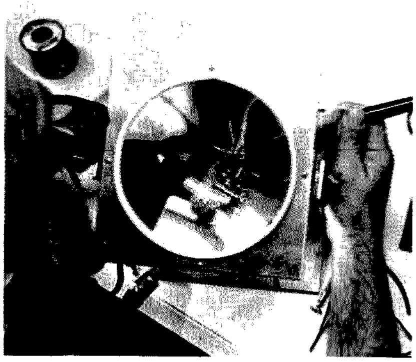

Photo 9.

The one fault it has is that I made the support legs a little short. Still, it is doing a heck of a job for me and in retrospect I don't know how I survived so long without it. I have also built myself a little device for holding my small (37 W) soldering pencil and controlling the heat of same – that no one who works with ICs should be without – but this is just a plug for another article.

Build yourself an IC-See-er and you can also wonder how you ever got along without one. ■

Build This Exciting New TVT

by
Louis I. Hutton K7YZZ
12235 SE 62nd Street
Bellevue WA 98006

About a year ago I decided to reactivate the RTTY mode of my station, and this article is a description of two of its facets: the keyboard and the television terminal. The keyboard development went reasonably well; then came the television terminal for RTTY, which I call the "RTTY TVT" for short. I immediately found that almost no data has been published on such a unit, with the closest thing being the computer TVT video readout devices. This problem was discussed at length both on the air and by mail with Dr. Robert Suding WØLMD, who suggested that I see what could be built using a low cost TVT circuit board kit designed by The Digital Group[1].

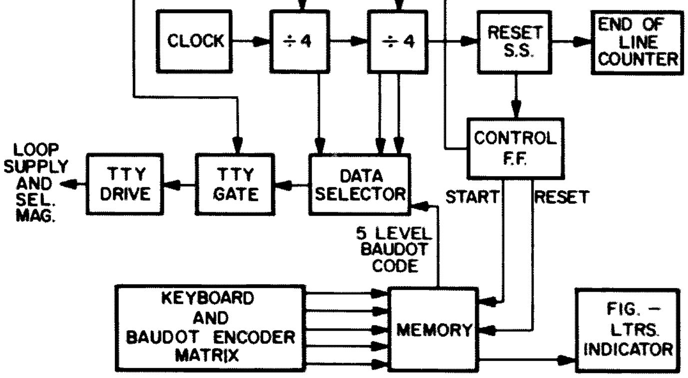

Fig. 1. Block diagram of RTTY keyboard.

PART ONE KEYBOARD

Several years ago I acquired a Model 15 Teletype machine, built up a tube type terminal unit, and enjoyed many years of operation with the green keys. This equipment was retired recently and a new project was begun to update the RTTY equipment. A 100 speed Model 28 KSR was acquired and the experiments begun. This article presents an effort undertaken to build a "solid state" version of the Model 28.

A literature search was conducted to find out what has been written with regard to the design and construction of a solid state keyboard for RTTY. A RTTY keyboard using the old RTL ICs was found in an article by Krupp several years ago, and in another by Horowitz about a CW keyboard modified for RTTY operation. Another article by Bell and Schmidt was located which presented a pre-coded message on RTTY. These articles gave me some ideas on how I wanted to design my solid state keyboard for RTTY.

The unit described in this article will permit the operator to generate the RTTY Baudot code at 60, 67, 75 or 100 wpm. It features LED indication of End Of Line, Figures or Letters mode of operation. As a result all fancy frills and extras are not provided, just a keyboard, using the 7000 series TTL IC chips. This is one of the advantages of building it yourself – no unwanted expensive extras.

Circuit Description

A block diagram of the unit is shown in Fig. 1. The clock speed is manually switch selected from 60 to 100 wpm speeds. The

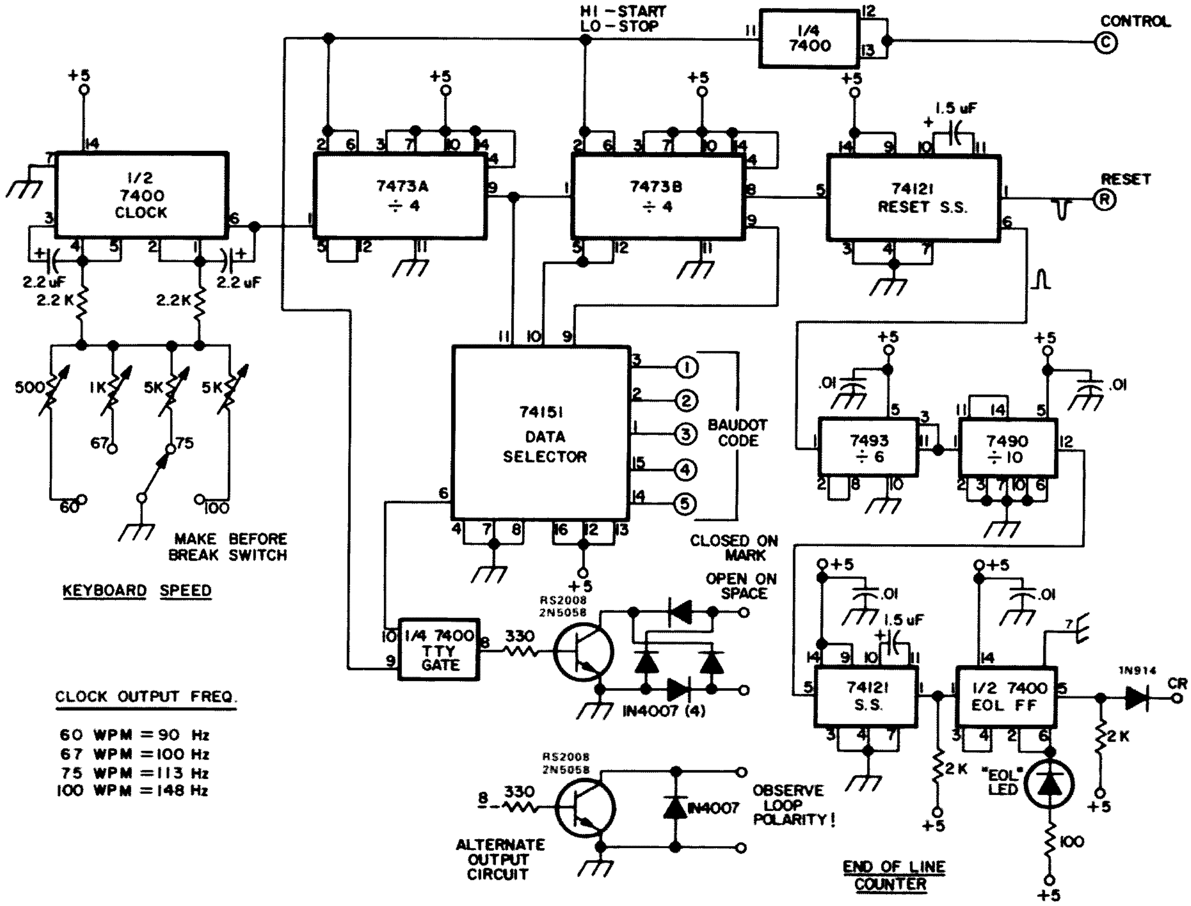

Fig. 2. Schematic diagram of RTTY keyboard.

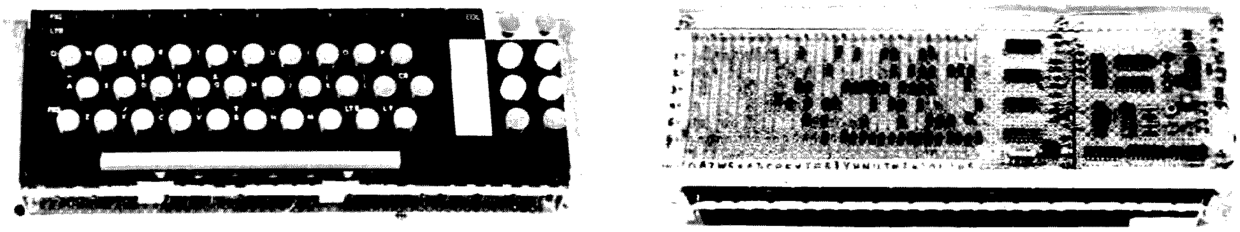
output of the clock (90.0 Hz at 60 speed) is fed to a frequency divider chain. The three frequencies taken from the divider at 60 speed are 22.5 Hz, 11.25 Hz and 5.6 Hz. These three are fed to the Data Selector which acts like an electronic version of a TD (Terminal Distributor). When a key is depressed the Baudot code for that key is set up in the Memory flip flop via the diode matrix. The output HIs and LOs from the Memory are fed to the Data Selector. A start pulse from the keyboard is also sent to the Control FF which unlocks the frequency divider chain and the RTTY Gate. For 176 ms (at 60 speed) the frequency divider chain transmits the selected frequencies to the Data Selector which then reads out the RTTY code set up in the Memory. This code consists of a series of 22 ms pulses: one start pulse, five Baudot code pulses and two stop pulses. At the end of the pulse train the Reset SS fires and the Control FF is reset. This action clears the Memory FFs and stops the divider chain from counting any further clock pulses. The RTTY pulses are fed from the RTTY Gate to the RTTY Drive output stage which is in turn connected to a diode



Top and bottom views of solid state RTTY keyboard.

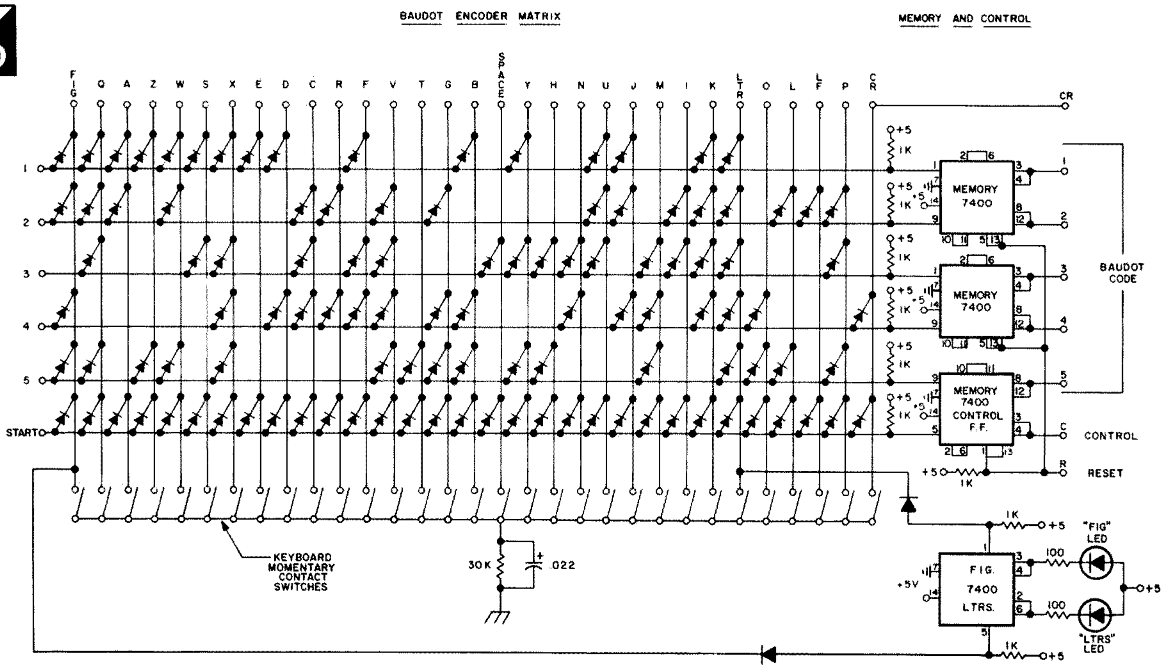


Fig. 3.

bridge permitting connection to a loop supply of any polarity. The End Of Line counter is used to indicate when 60 keyboard actions have been taken after a Carriage Return function has been keyed. This is used when the keyboard is used for driving a tape puncher. When the FIG key is depressed an FF is set and the FIG LED is lit. When the LTR key is depressed the FF is reset and the LTR LED is lit. Depressing two keys simultaneously will cause an error in the output. No mechanical or electronic means are provided in the low cost unit to prevent this event.

Construction

A surplus computer keyboard was purchased from a surplus house that advertised in *73 Magazine*. This unit uses magnetic reed switches and has plenty of extra keys for other functions that are planned for in the future. The key tops were removed and the computer markings replaced with decals of the standard RTTY upper and lower case markings. Since the keyboard already had a very nice set of numbered keys I put them on the top row, which made it not quite like a Model 15 or 28 but a bit more like a typewriter. Again, with home brewing you can make it to suit yourself.

Two metal rails were formed and attached to the bottom of the keyboard unit on metal spacers. A long piece of perforated fiberglass board 4" by 8½" was fitted in between those two rails as seen in the photographs. The diode matrix, Memory, Control FF and FIG/LTR FF were mounted on that circuit board. This configuration permitted me to conduct circuit design and debugging on a second small board containing the remainder of the circuits. The second board is 4" by 3¼". If one wishes, a board 11¼" long by 4" wide could be used for all the circuits, now that the unit has been designed. The ICs are fixed, mounted and hardwired into the circuit. Since this is not a production item no effort was made to design a PC board.

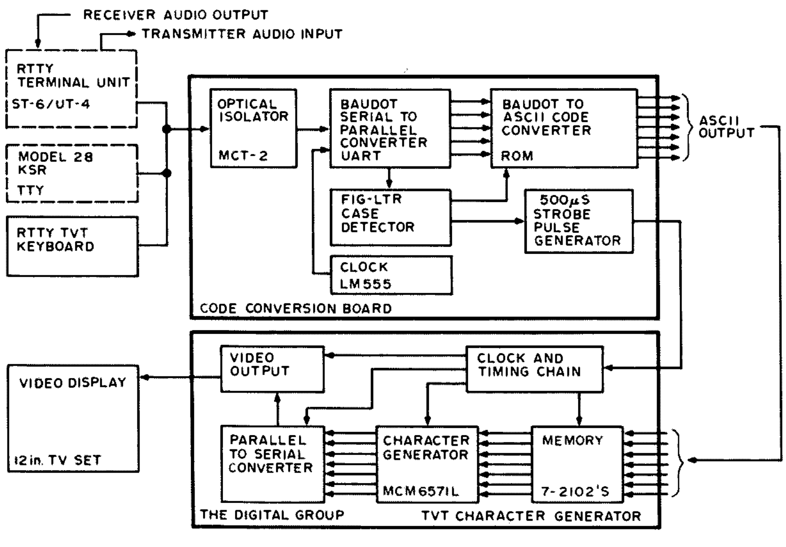

Fig. 4. Block diagram of RTTY TVT.

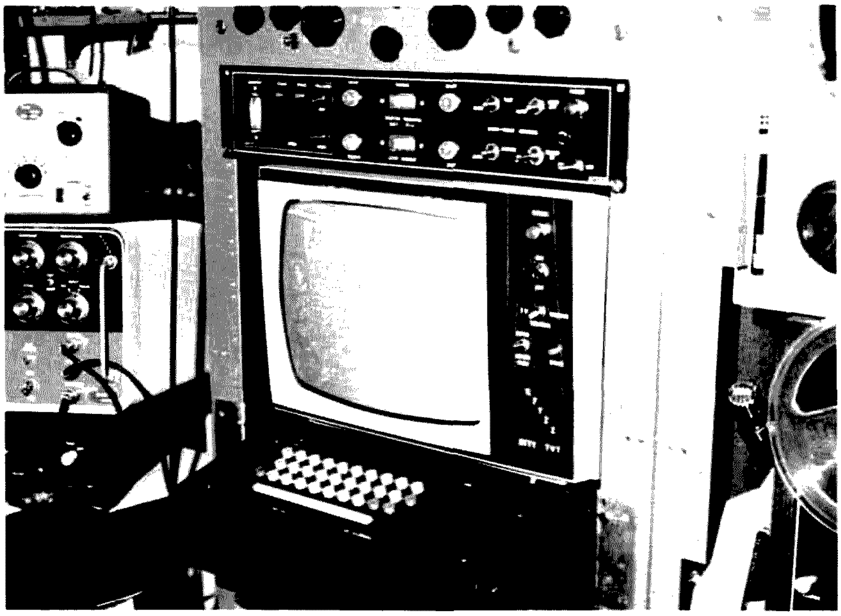
Testing

The long circuit board was wired first, and a manual jumper was wired from the keyboard key grounding capacitor and resistor to test out the diode matrix and memory before wiring keys in the circuit. A jumper was wired from the reset line on the memory that was momentarily grounded to reset the memory. The wire from the key circuit was touched to the selected diode matrix letter and then the five Baudot output lines were checked for proper high and low states. Each diode in the matrix represents a mark or high state. The absence of a diode represents a space or low state.

The diodes used in the matrix were of the fast switching type used in computers. I used some obtained from Radio Shack which carry their part number 276-114. They come in a bag of 50 each and must be tested.

When checking out the small circuit board the first thing to test is the clock. I monitored the pin 1 of 7473A to see if the clock was oscillating in each position of the speed selector switch. That switch must be of the make-before-break type for proper



The RTTY TVT.

operation of the clock. Each adjustment pot was set to give the proper speed according to the chart on the schematic. At 60 speed, 90 Hz should be appearing at pin 1 of 7493A, and with the control line high at pins 2 and 6 of each of the 7493s you should get 45 Hz at pins 5 and 12 of the 7493A. Pin 9 should be 22 Hz. Pins 5 and 12 of the 7493B should be 11 Hz, and pin 8 of the 7493B should read 5.5 Hz. A negative going pulse of around a half a millisecond should be seen reoccurring each 176 ms on pin 1 of the 74121 Reset SS. With a temporary ground on pins 2 and 15 of the 74151, the output as monitored on pin 6 of the 74151 should read low, high, low, high, low, high high, repeat, etc., in a serial bit stream. If a temporary ground is placed on pins 2 and 6 of the two 7473s the bit stream should stop. If all works OK at this point, then remove all the temporary wiring and wire the board in the circuit with the encoder board.

As a final test I wired the output in series with the loop supply and printer magnets of my Model 28 KSR and was able to type out a copy on a local loop using the keyboard and the Model 28 printer at 100 speed. I ran into some noise problems and had to add some power bus bypass condensers on several of the ICs, and these are so noted on the diagram.

This unit was a very interesting project and it was a very good feeling when I finally got it assembled and running with my printer. The circuit development took several months of breadboarding to get all the various parts of the unit tested before tying them all together in the finished product. I wish to thank Mr. John Small and

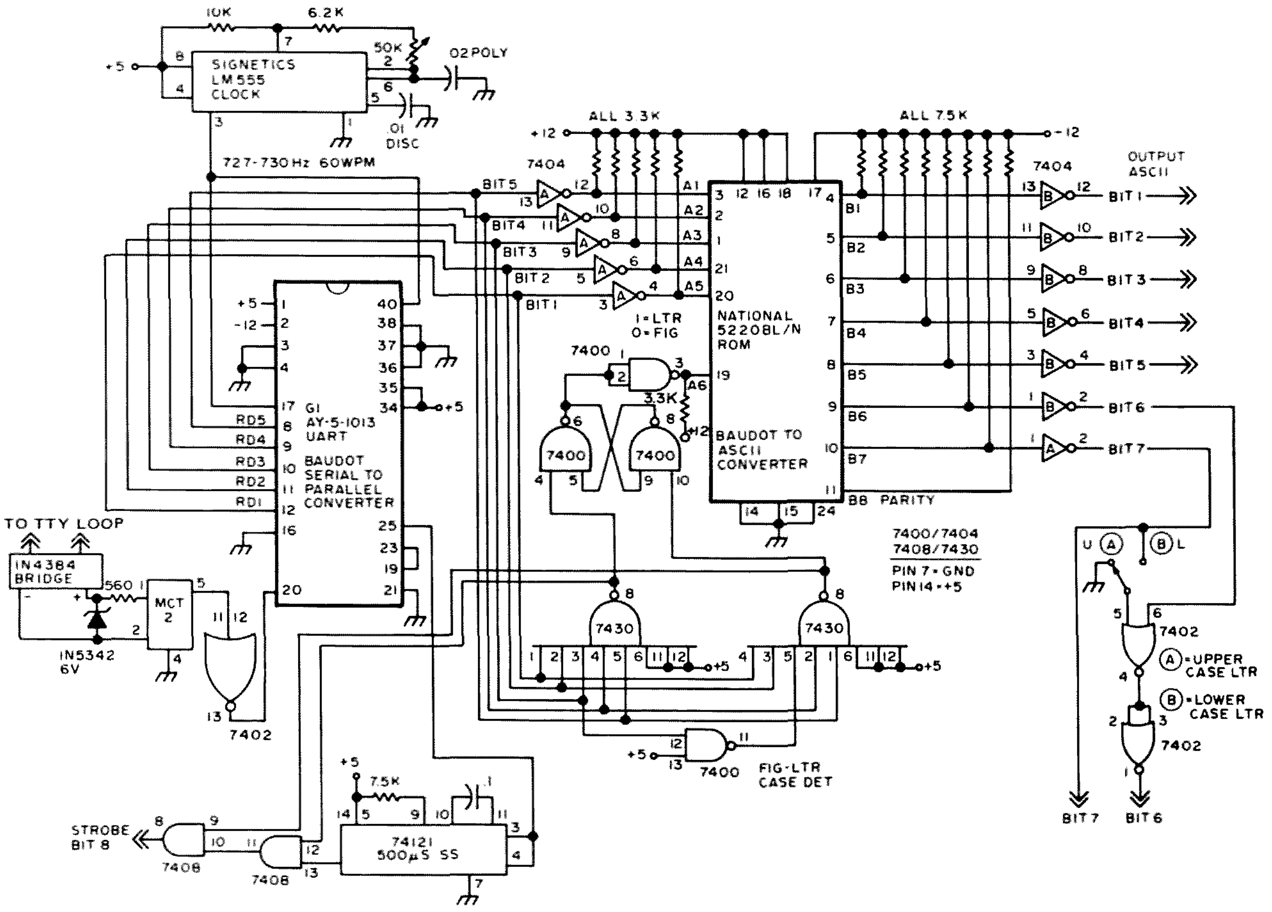


Fig. 5. Baudot to ASCII TTY code converter. Note: If FIG-LTR state on pin 19 (5220 BL/N) is incorrect, rewire 1-2-6 of 7400 to 1-2-8 of 7400.

Mr. T. Jackson who were most helpful in keeping my thinking straight as I developed this unit.

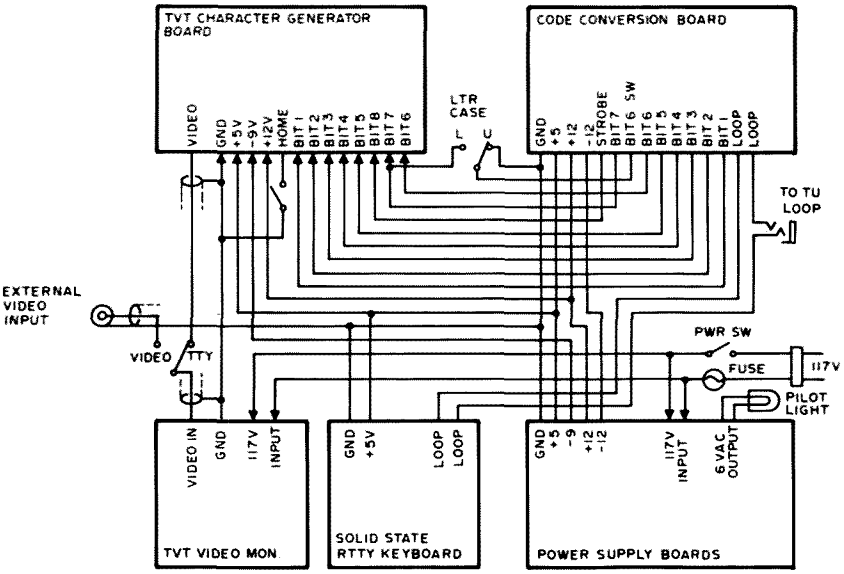

Fig. 6. Intercabling diagram.

PART TWO
TELEVISION TERMINAL

There are two approaches to getting that RTTY signal on a TV set. One way is to make the keyboard output the ASCII code so that it could talk to the TVT without any conversion. This method also requires both send and receive code converters to get the Baudot code converted over to ASCII to be compatible with the display. Also, when you send from your ASCII keyboard it must be converted to Baudot so the other chap's machine can print the message. The second approach is to use a keyboard that only sends in Baudot and make only one conversion from Baudot to ASCII so that the TVT could read the incoming signal from either the keyboard or the terminal unit. This is the approach that I used, and the results of my efforts are described here.

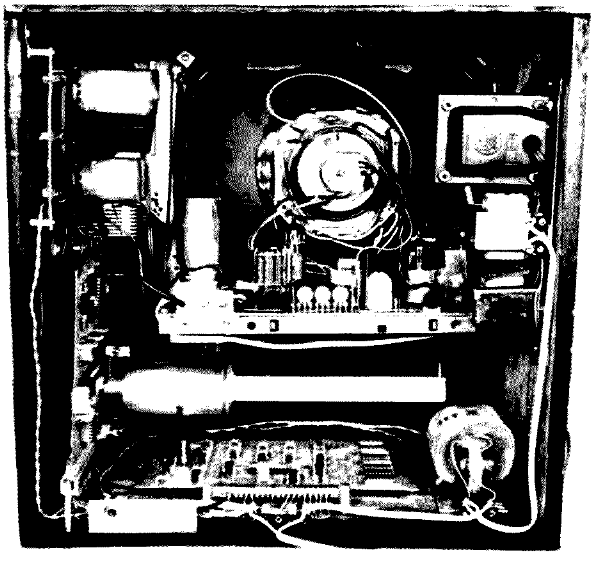
This unit includes a surplus keyboard rebuilt to include a diode matrix for encoding and generating the Baudot code at 60 wpm. The output of this keyboard is used to key the ST-6 loop and the TVT through a code converter board. This circuit board converts the Baudot encoded bit stream coming from the ST-6 or the keyboard from serial to parallel Baudot data. The parallel Baudot data is then converted into parallel ASCII data and a strobe pulse is added to trigger the TVT display circuit. The parallel ASCII is fed to the character generator circuit board and onto the TV screen. The display has eight lines of thirty-two characters per line. When the last character is printed at the bottom right-hand side of the screen the printout returns to the upper left and erases the existing character and prints the new one as it progresses across the screen line by line.

A HOME push-button switch is provided that will return the writing beam to the upper left-hand corner of the screen. An upper and lower case letter selection switch is also provided as that feature is available in the TVT circuit board by The Digital Group. Since this board was used in a microprocessor computer terminal, it has Greek notations which cause some glitches in the Baudot scheme of things. These were most troublesome in the FIG and LTR modes. The code conversion board has circuits incorporated to tell the character generator to ignore those key functions in the Baudot system. All other frills and extras were left out of this terminal to keep the cost down. It is estimated that one could probably be duplicated for anywhere from $250 to $350 depending on how many surplus components were used.

Circuit Description

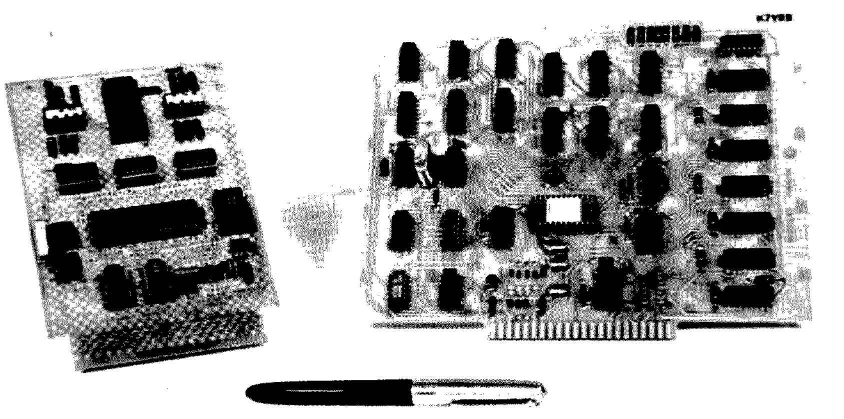
A detailed description of the design and operation of the keyboard has already been presented. A block diagram of the RTTY TVT is shown in Fig. 4. The input to the code conversion board is made to the ST-6 loop circuit through an optical isolator to keep the loop high voltage from the five volt TTL circuits. An UART (GI AY51013) is used to convert the serial Baudot to a parallel Baudot output where it is fed to the input of a code converter ROM. The clock (LM555) for the UART is set for 60 wpm speed (727 to 730 Hz). In the code converter, a National 5220BL/N ROM, the Baudot code is changed to the ASCII code.[2] A figures-letters function detector is used to tell the code converter to include either bit 6 or bit 7 in the ASCII code output. The case detector is also used in conjunction with the strobe generator to eliminate the Greek letter that would normally appear on the TV screen when the FIG or LTR key is touched. A strobe of at least 500 microseconds is required at the end of the generation of each character on the TV screen. The strobe generator is triggered by the output of the UART transmitter section.

The ASCII output, along with the strobe line, is connected to the TVT character generator board. The video output from the TVT board is connected to the video input of a modified TV set. To prevent the TVT display from returning to home position after every time a CAR RET is keyed, IC30 (7430) is removed from its socket. A 2.2k pull up resistor is connected between pins 8



Internal view.

and 14 of the IC30 socket. A wire is run from pin 8 of IC30 socket to pin 14 of the PC board connector. This is the reset "HOME" terminal. When this terminal is grounded momentarily via a push-button switch it drives the write beam of the CRT to the beginning of the first line on the display. This is the only modification required to The Digital Group TVT circuit board to get it working as a RTTY TVT circuit board. The video readout of the RTTY TVT unit is a salvaged 1969 Sears 12" portable TV set. This set came from a junk yard, and to put it into use as a video monitor all the circuits were removed except the sweep, video and high voltage. It makes a very acceptable video monitor for this application.



The two PC boards.

Construction

The cabinet for the RTTY TVT is constructed from plywood and is 15" high by 15" wide by 15" deep with about 4" sticking out in front to house the keyboard. The outside of the cabinet was sanded and given two coats of shellac. The edges of the cabinet were painted a dull black. The remainder of the exterior of the cabinet was covered with simulated wood grain sticky-black plastic covering obtained from a hardware store. This makes a really nice looking cabinet. The panel holding the keyboard was also covered with this same simulated grain material. A metal panel was fitted over the holes left by the removal of the TV tuners and controls, and was covered with the simulated wood grain material.

The power supplies were constructed from surplus parts and are mounted by metal standoffs to the inside of the cabinet. The circuit board containing the code conversion circuit is 4½" wide by 6" long. The TVT readout board is 8" wide by 6½" high. A diagram of the code conversion board is shown in Fig. 5. The overall intercabling diagram for the RTTY TVT is shown in Fig. 6.

The conversion of the 12" TV set for use as a video monitor required considerable time as the set was in pretty bad condition. The filaments of the four tubes used were rewired so that they would work from lower voltage circuits. I did not want to run the thing from the power line direct like it was originally wired. I used a small isolation transformer to supply the 120 volts for the power supply input. I found that both the yoke and flyback transformers were defective and had to be replaced using parts from other discarded sets. Fig. 7 is a schematic of how I accessed the input to the video amplifier of the rebuilt set. The original set used a tube to rectify the high voltage to the picture tube and I replaced that with a solid state high voltage rectifier removed from another junk set. This helped to further lower the current drain on the set. The front part of the old set's cabinet formed the front of the TVT unit. It was attached to the plywood cabinet by handmade metal brackets. The panel to the right of the picture tube contains all the controls for operating the RTTY TVT. These are the pilot light, power switch, video monitor or RTTY monitor selector switch, upper case-lower case letters selector switch, and the HOME switch. The CRT brightness and contrast controls were mounted on a small metal plate fastened to the rear of the TV chassis. They are set once and left that way.

Test and Checkout

Since I was developing many of the circuits to put this thing together, I ended up by running all sorts of tests during that time. Many of them are not needed for someone essentially duplicating this circuit. When the code conversion board is finished, the input to the board should be connected to the output of the keyboard and the ST-6 or terminal loop supply. This way you can send Baudot encoded characters to the board one at a time to see if they are being encoded properly at the output of the board in the ASCII code. The clock must be set for an output frequency of from 727 to 730 Hz as measured at pin 3 of the LM555 (60 wpm). Each time a key is depressed on the keyboard a pulse of approximately 500 microseconds should appear at pin 8 of the 7408 gate. There should be no pulse appearing at that point when the FIG or LTR keys are keyed. A "high" or 1 should appear on pin 3 of the 7400 when the LTR

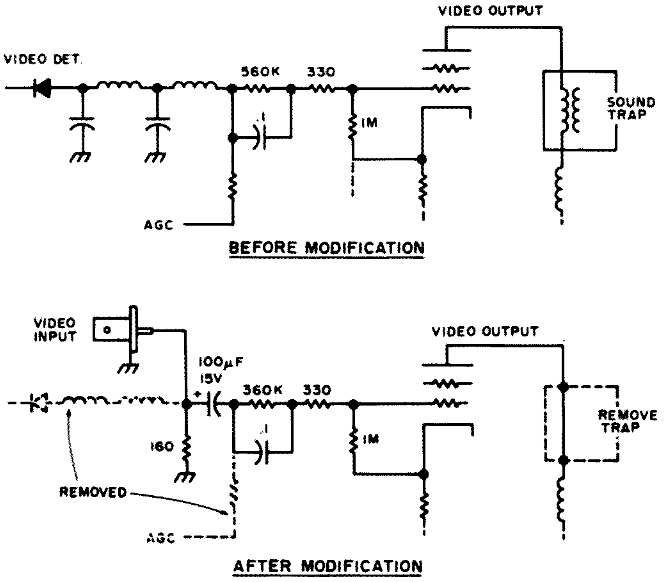


Fig. 7. Video input modifications to 12" TV set.

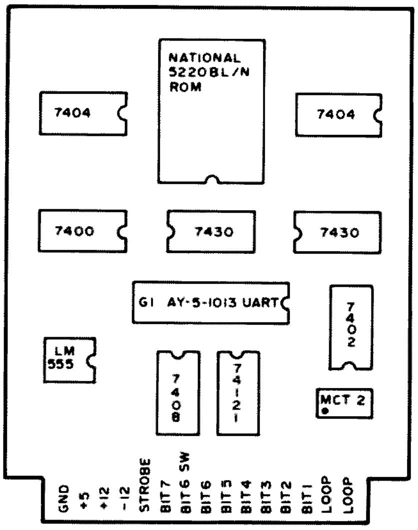

Fig. 8. Major parts layout, Baudot to ASCII code conversion board.

key is depressed, and a "low" or 0 should appear on pin 3 of the 7400 when the FIG key is depressed. Pin 5 of the 7402 should be temporarily grounded so that the output of the code converter may be checked.

Key in the letter A on the keyboard. Now look at the output of the board and bit 1 and bit 7 should be high and all other bits low. Now try the letter R on the keyboard. Only bits 2, 5 and 7 should be high on the ASCII output. Now try the letter Y and the ASCII readout should have 1, 4, 5 and 7 high. Now key the FIG key and then the number 2. The ASCII output should have only 2, 5 and 6 high. On FIG operation bit 6 of the code is used and on LTR bit 7 is used. If at this point you are getting this kind of response on the ASCII output you are in fine shape. The next thing is the character generator circuit board.

The circuit board data furnished by The Digital Group with their TVT character generator gives very detailed step by step instructions on how to check out their board and will not be repeated here in this brief article. I had an old 1950 Admiral TV set that I had previously modified for use as a video monitor with a camera for fast scan to slow scan conversion construction project. I used this set to test out the TVT board and to check out the system from keyboard through the code converter through the TVT board and onto the TV set. This way I was sure all bugs were worked out before I mounted the parts in the cabinet. The TVT circuit board performed as designed with only a slightly defective memory chip giving me any problem. This bad chip caused the wrong character to appear in certain lines on the screen. When replaced by the vendor it worked perfectly.

When connecting the input of the RTTY TVT into my ST-6 I had a polarity problem and had to reverse the input leads to the RTTY TVT to get it to print properly. This was the only interfacing problem encountered. I have my Model 28 KSR wired in series with the loop driving the RTTY TVT and if I want a hard copy I just turn on the power switch on the machine motor and the copy is printed.

I would be interested in hearing from those who decide to build one of these RTTY TVT units and will try to answer any questions they may have about the machine. All I ask is that they include an SASE. 73s and good printing on your CRT. ■

Magic Fingers for RTTY

If you have speedy fingers, never have RTTY problems (ha!), or have built your last perfect RTTY AFSK unit and have it all tuned up, more power to you. If, however, you are like most of us and have two thumbs per hand, a Model 19 that periodically has spasms of TIN-GT's (this is not *&#% going to's), or ever experiment with building new ideas in AFSK gear, you can sure use the item I am about to describe.

I think the circuit to be described, when coupled to a tone source, is the handiest gadget I have ever built for RTTY. It gives you any RTTY character or the RY test combination automatically repeated over and over. While you can use various tone sources, from a modified AFSK sending unit to the new tone generators like the 566 IC that is TTL compatible when run correctly, I highly recommend using the very accurate and stable tone source described in an article by Dr. Robert Suding WØLMD in the July 1975 *73 Magazine,* page 98. The generator is great and apt to be the starting point for many projects and articles of mine in the future.

Ever since I built the first one (I now have 3 in one form or another), I have been sold on the unit and keep building gadgets to put it to more use around my bench and ham shack. One is the unit to be covered in this article, another I have written up and built as an SSTV generator producing gray scale with sync, and the third will be forthcoming for use with touchtone equipment and repeater users may find it of interest. A fourth is in progress at the time of this writing for use with SSTV in the form of copying the weather satellites.

Project Outline

This little adapter unit will provide you all the RTTY tones (and SSTV) if you use it with the original tone generator by WØLMD. Further, it gives you automatic generation of the "RY" alternating letters used as a standard Teletype test because of its alternating Mark-Space format. For those just getting into RTTY, I am referring to the normal 7 part, 5 level code used by amateurs. All characters start with a Space tone from the "Mark-Hold" tone that keeps the machine (Teletype) quietly sitting there and not chattering away. Then the next five units are either Mark or Space, depending on the character sent. The final or seventh unit is always a Mark, usually sent 31 ms long (the rest are each 22 ms) to be sure some of it makes it through to end the character. Only a small part of the 22 ms units is really used, too, but all is usually sent to be sure of recovery in spite of fading, noise, etc. This unit uses all 22 ms units (often called Western Union because that is the format they use), the reasoning being that the unit

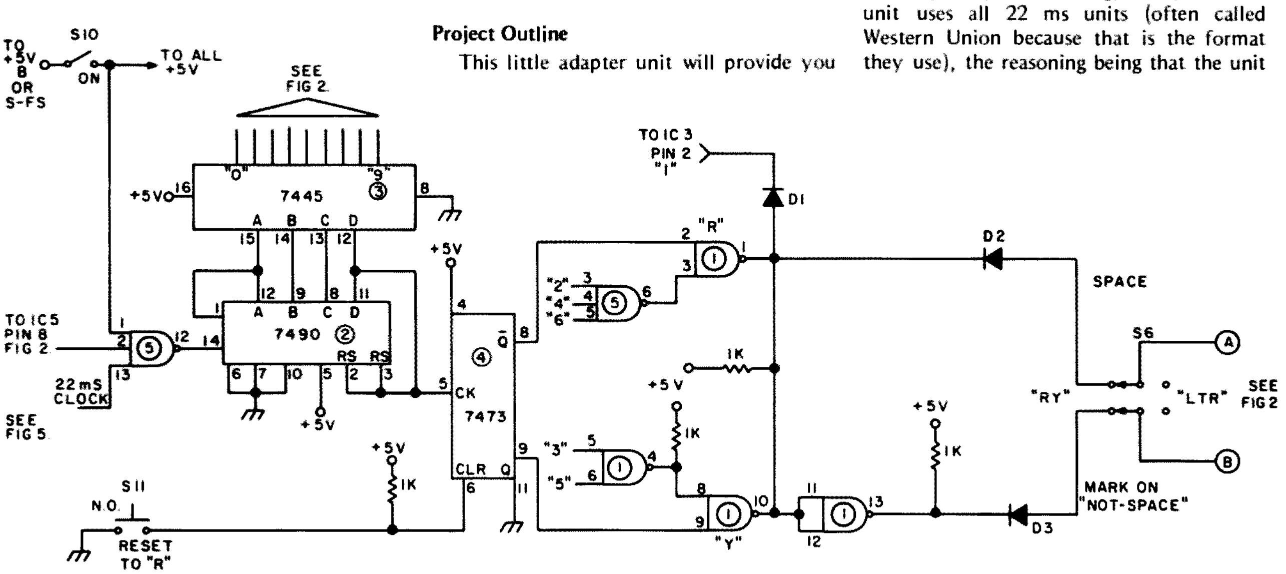

Fig. 1.

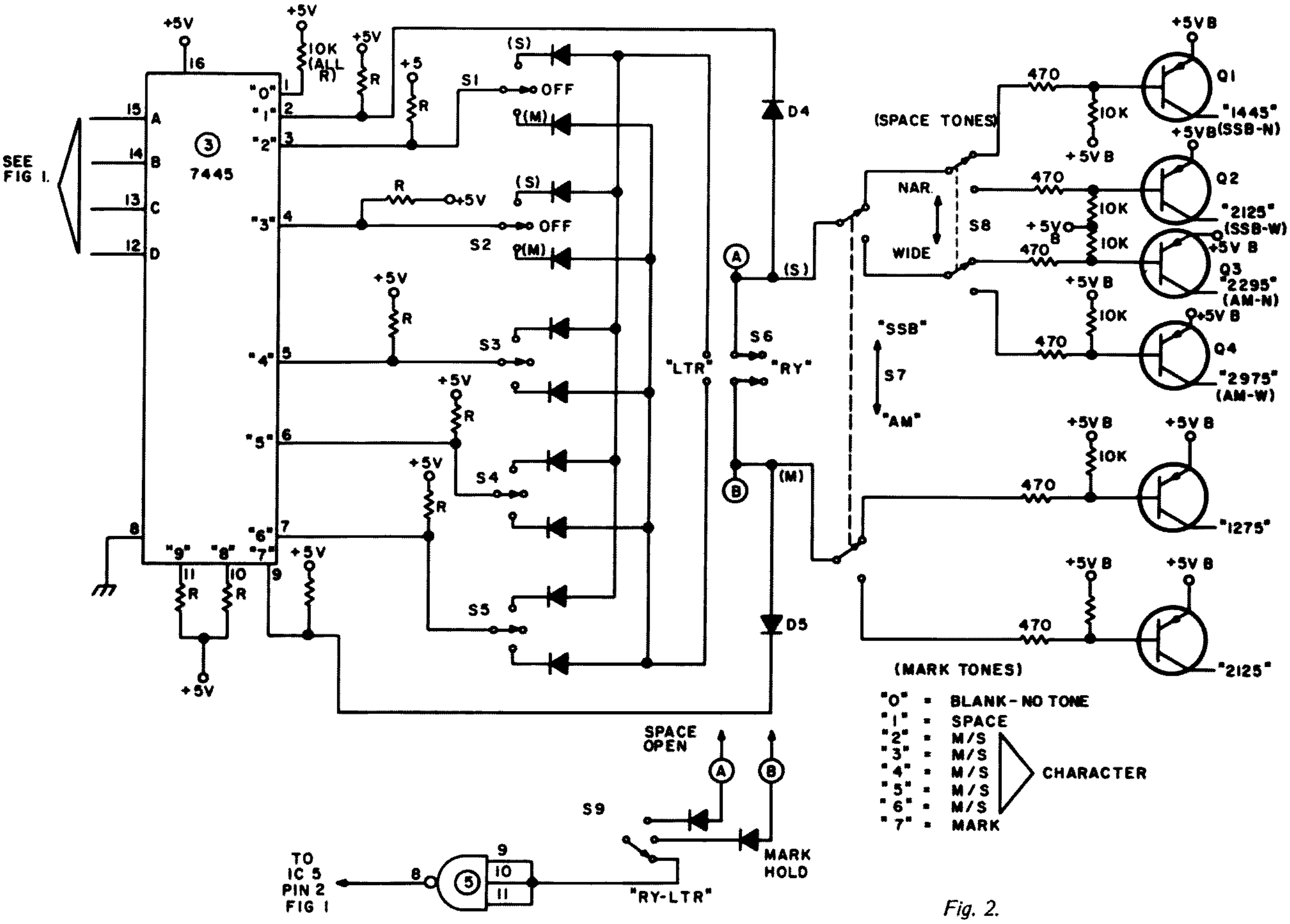

Fig. 2.

will be hooked right into the RTTY AFSK unit, and noise and fading are definitely not a problem in such a case. Secondly, it greatly reduces the hardware required.

A few words on switching are in order at this point. Switches added for the automatic character sending are: (1) S-1 to S-5, which are 3 position slide switches used to set up a character of your choice, to check out the TTY machine or one of the "SELCAL" type decoders if you are building such an item. Fig. 3 shows the actual slide switch form instead of functionally as in Fig. 2. (2) Switch S-6 is used to choose whether a "letter or figure" is sent or the "RY" pattern. (3) Switch S-7 is a DPDT unit marked "SSB-AM." What is really meant is whether the newer-lower tones that will pass through an SSB receiver filter are sent, or the older-higher audio tones used on AM type operation are chosen. (4) Switch S-8 chooses whether the older shift standard of 850 Hz wide (W) shift is sent, or the newer shift of 170 Hz narrow (N) is the result.

S-1 through S-5 are set up by using a chart of the required Mark-Space combinations for the character you desire. S-6 is set to "RY" for the automatic RY test, or to "LTR" for using S-1 to S-5 and a letter. S-7 and S-8 will depend on your use, equipment, and tones that you require.

S-9 is a function switch allowing a continuous Mark-Hold tone for 1275 or 2125 Hz Mark channel adjustments. It also stops the Teletype from chattering away while you change to a new letter or to RY combination. A second choice of S-9 is the Space-Open. The machine will run "open-loop" and chatter away if on, but you can adjust any of the four frequencies used for the Space channel depending on the setting of S-8 and S-7. The last position chooses the automatic mode, either "RY" or "LTR" depending on the setting of S-6.

S-10 is an on/off position to allow this unit to be used with the original tone generator when in the on position, and other gadgets to use the same tone generator when turned to off. In the off position, +5 V is removed from all +5 V points in the adapter except the electronic switches (transistors) used to key on the tone desired. The transistor emitters are supplied directly from the +5 V bus and have +5 V whenever the tone generator is on.

A word about the original tone generator as it applies to this adapter. All of the 7430 ICs with SSTV outputs can be eliminated if you want an RTTY only unit, thus reducing the overall cost. These ICs have SSTV frequencies of 1200, 1700, 1900, 2100 and 2300 marked at their outputs pin 8. The 7410 used to decode 1500 at pin 12, 1275 at pin 6, and 2125 at pin 8 must remain due to the two RTTY frequencies involved, but pins 1-2-12-13 need not be wired. The 7430 that has all the SSTV frequencies at its input can be eliminated and the 7402 pins 5 and 6 tied together. You may note that only half of the 7473 is used in the original tone generator, and you may feel free to use the other half for the RTTY adapter IC-4 by using the numbers shown in Fig. 1 and save some money.

Now that the unused ICs are out and the other half of the 7473 is used for the RTTY unit, you need only IC-1, a 7401; IC-2, a 7490; IC-3, a 7445; and IC-5, a 7410. A typical total cost of all these is $1.82. But you say, "Yeah, what about the tone generator?" If built as I described above for RTTY only, the IC cost for all ICs – tone generator, RTTY unit, and power supply IC – is only $6.45 plus $1.82, or $8.27. The power supply 309K is $1.95 of that cost, but I highly recommend its use. You must increase the power supply transformer to one with a 1 Amp rating, but that is the only power supply change.

My suggestion for wiring eliminates the switch in the original tone generator and replaces it with the electronic switches as shown. Each RTTY tone can be gotten alone or automatic mode is possible. If you choose to retain the SSTV mode, then merely rewire the switch as a seven position switch,

per the original switch for the first six positions A through F. (NOTE: The original Fig. 1 shows 2100 and E in position 6 which should be 2300 and F.) Then use Fig. 4 to wire up position 7. This allows normal SSTV use for six positions, and position seven puts you in RTTY function all with a single pole rotary switch and only +5 V being switched around.

Circuit Description – Logic

By placing a square wave with a 22 ms period into pin 13 of IC-5, and S-10 being on, the encoder IC-2 (7490) will begin to count. Its BCD lines are decoded in the decoder IC-3 (7445), and one line at a time from "0" to "7" goes low. The encoder and decoder is prevented from counting "8" or "9" by tieing the D line back to the encoder reset gate, resetting the counter as it tries to go to "8" (D-high). The D line is used for something else to be explained in RY generation. In the "LTR" mode of operation the lines "2", "3", "4", "5" and "6" cause Marks or Spaces to be generated depending on the settings of S-1 to S-5. Line "1" always generates the characteristic Space first unit, just as "7" always generates a Mark final or Stop unit. Switch settings as described decide what exact tones are generated for each.

RY Generation

The test pattern is a bit more complicated, but not greatly so if you break it down. IC-1 marked "R" can do *anything* only when IC-4 pin 8 is high. Likewise, IC-1 marked "Y" can only get a low output when IC-4 pin 9 is high. These two pins of IC-4 cannot both be high at any one time. Therefore, let us follow through an R generation, that is S – S - M - S - M - S – M (S = Space, M = Mark). Remember the first Space and the last Mark are put in for any automatic LTR or RY by lines "1" and "7" of IC-3, and won't be covered over again. The R is generated when IC-4 pin 8 is high, so let's start as though S-10 is turned on and then the "Reset to R" push-button S-11 is pushed. S-6 is in "RY" and S-9 in "RY-LTR." When the counter and decoder reach "2", IC-5 pin 3 goes low, IC-5 pin 6 goes high, and IC-1 pin 1 goes low. This low

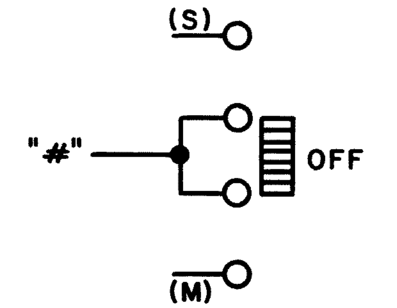

Fig. 3. S1-S5 switches: 1P3T. Center off position allows the generation of false characters to check logic-type decoders. It can be deleted and SPDT used if not wanted.

through S-6 and on through the chosen space frequency switch causes a Space tone to be generated. When advanced to "3", IC-1 pin 5 goes low, and pin 4 goes high, but since IC-1 pin 9 is low, IC-1 pin 10 stays high. Since both IC-1 pin 1 and pin 10 are high, and "1" is high (see D1 Fig. 1), all inputs to IC-1 pins 11 and 12 are high, and its output goes low causing an appropriate Mark tone for the switches S-7 and S-8 chosen. Diode D1, incidentally, defeats the Mark switch IC-1 pins 11-12-13, during the first "1" Space required by all letters and figures and is used in RY mode only. It appears to key the Space by the path through D2, but a better path is found through D4.

As the counter advances to "4", the same action as "2" results using IC-5 pin 4 instead of pin 3. Again at "5", the same as "3", using IC-1 pins 11-12-13 for a Mark. And finally at "6", again as in "2" and "4", using IC-5 pin 5. "7" sends its Mark as well as the low at IC-1 pin 13. This just happens to insure Mark sent when in RY mode only and is just a logic result and not intentional.

To generate a "Y", the same kind of logic applies throughout with "3" and "5" creating Spaces for the Y or S – M - S - M - S - M – M. The "3" and "5" control IC-1 pins 5 and 6, and function just as "2", "4", and "6" did into IC-5 pins 3-4-5. The one change is that following the generation of "R" above, the D line returning low and resetting the counter also sets IC-4 to the opposite state with the Q pin 9 high, and allows IC-1 pins 8 and 9 to control the tone generation. IC-4 (7473) continues to change state (toggle) after each pass of the counter to "8" and the D line falling from high to low. This is a narrow pulse just wide enough to reset the counter and toggle IC-4. The toggling of IC-4 produces alternate use of IC-1 "R" and IC-1 "Y", producing the RY tone sequences.

Position "0" allows a 22 ms opening to be inserted before each new character whether in RY or LTR mode and gives everything a chance to settle down. This makes up in part for the seventh (unit 7) Mark being only 22 ms wide.

Summation

Since the unit will probably be used into an AFSK unit, the filter shown in Fig. 6 should be used at the output of the tone generator to make the output into a pretty good sine wave. It is lifted exactly from an article by Bert Kelley K4EEU in July, 1973, *Ham Radio*, page 6. It worked so well on the SSTV adapter I built and mentioned earlier that I have sort of adopted it – hi! It passes the SSTV nicely, too, so you can use it even if you build the total combination unit SSTV/RTTY.

A couple of tips are in order if you are building an AFSK unit and are going to use this adapter to set things up. (1) Don't overdrive your filters; some type of compression limiting is highly desirable, coupled with an AGC system in your audio channel of the AFSK unit. (2) Consider a pair of active T filters in tandem as a front end. A switch selected resistor tunes each of them to the right high-pass and low-pass frequency easily. This tandem pair forms a bandpass circuit rejecting low frequency noise and high frequency chirps and peeps you tune across (and that tune across you). And finally, (3) DO try a trick I have learned from EME and Oscar listening that works gangbusters on RTTY for tuning. Do build the AFSK unit so that the incoming signal decoded into a dc shift in level keys your AFSK tone generator for sending – even when receiving. The keyboard controls it sending, and the incoming decoded dc shifts controls it on receive. This allows you to put a monitor and speaker/headphone jack on the AFSK sending unit's output. Obviously you can now monitor your sending for openers, but the best deal of all is receiving/tuning. Feed the output direct from the receiver speaker output to the AFSK receive input and the right or left earpiece of your headphones. Next feed the monitor output to the remaining earpiece of the headphones. Tuning becomes a snap – make the receiver sound like the monitor! Build the AFSK unit to have Mark-Hold in the absence of signals. As you tune in on a RTTY signal it will have one note (Mark) that sounds more and more like the other earpiece (monitor). As you tune closer yet, your decoder begins

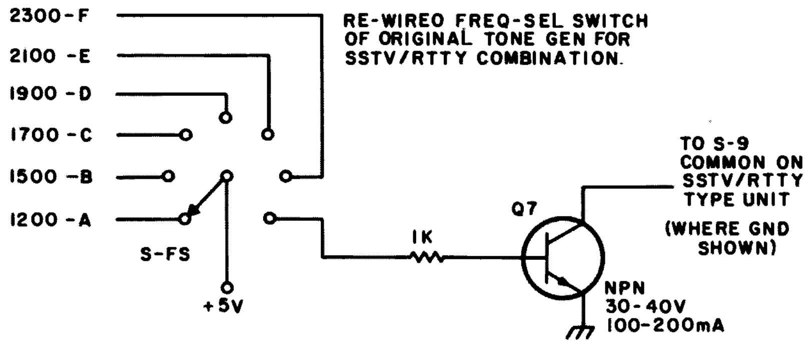

Fig. 4.

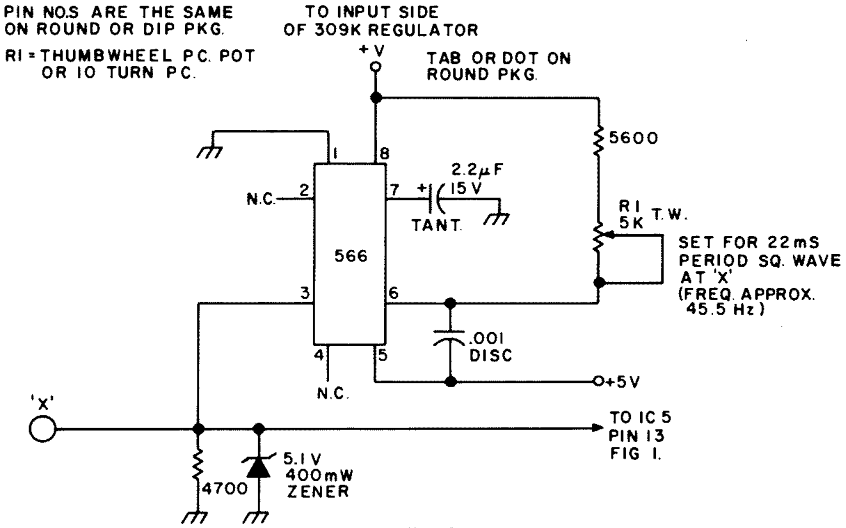

Fig. 5.

working and the machine comes to life since now it sees Mark-Space changes. Make the two sound alike and you are in the money.

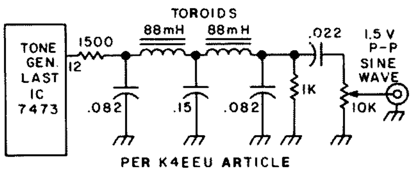

Fig. 6.

Sneaky way to tell in a hurry if he is on narrow shift and you on wide, etc., if either will key your decoder, but your AFSK sending unit is set up (switched) to the wrong shift — the Space tones never match — only the Mark tones!

Per usual, an SASE will bring whatever help I can be, but there should not be much trouble with this one with so few parts and wiring. For that reason, there is no circuit board layout. If enough guys want one, I guess I could lay one out for this and the SSTV unit. I built mine right into the RTTY rack mounted control unit. It also contains such things as a K2OAW CW identifier which was part of a repeater control by Pete. I just put a solid state timer or manual switch control into it, and it sends my call either every ten minutes if I send that long straight, or at the beginning of each transmission. I begin all transmissions with a blank key which sends nothing on my machine, but momentarily breaks the loop. Anytime the loop breaks, a PTT arrangement like VOX keys the transmitter, and the identifier identifies by shifting the Mark tone a small amount, but not enough for the other guy's unit to leave the Mark-Hold and print garble. This is quite legal and a widely used means of CW identifying. When it is running (10 wpm CW), the keyboard is disabled and the line over-run lamp on my Model 19 blinks in step with the CW being sent. Really quite easy, and sure makes RTTY a lot more fun than keeping one eye on a clock, your fourth hand keying the transmitter, etc. It is a collection of other guys' articles plus some original ideas all boiled into one small package by sharing parts, but I guess I should write it up if there is still interest enough in RTTY anymore — it sure works well.

Hope you enjoy the adapter, and a little careful wiring should have it working right the first time. TTL and digital things work that way — wire it right and it loves you. ■

What's That In Binary?

My first introduction to the world of computers left me with a reaction similar to the one I had when I saw my first schematic of a single sideband rig. The HHW* flag came up in every register.

I also tend to break out into a rash when real math comes my way, which is not the best reaction when starting to shake hands with computers.

Since others of the ham fraternity may suffer similar reactions, I have dredged the contents of my SVM** to recall a simple way of converting a base ten number into the binary numbering system or into the octal system of notation.

Interestingly enough, I was exposed to this method some thirty-five years ago, in, of all places, a Latin class. The instructor believed in making things come alive by spending some class time showing us how to multiply and divide Roman numerals. Computer stuff, by comparison, is mere child's play – and it is no wonder the barbarians wiped out Rome. It had to be painfully obvious that the Romans were so busy XXVIIing it that they had no time left to fight a mere war.

Here is a little something for my fellow non-math lovers:

$$A_{1b} + A_0 + \sum_{1}^{\infty} a^{-1}\ b^{-1} \ldots$$

It is perfectly obvious that this little bit of razzle-dazzle contains all the wisdom needed to convert a number of any base or radix to a number with any other base. For example, a decimal number to a binary number or an octal number to a decimal number.

Rather than trying to unscrew the unscrutable by translating this little gem into basic English, let me pass on a simple nuts and bolts nugget of wisdom derived from said mathematical mouthful.

Specifically, let's examine a way to convert any decimal number, such as 19758 or a number of your choice, to binary or octal. All you need is the native ability to divide by two or by eight.

Decimal to Binary Conversion

1. The digits as derived are set down right to left, the rightmost digit being the least significant bit and the leftmost digit being the most significant bit.

2. We divide the number first into odd or even by inspection. If the number is even we automatically make the least significant bit a ZERO. If the number is odd, we make the least significant bit a ONE.

3. Now we proceed to divide the number by two in a series of successive divisions. We ignore fractional remainders produced by the divisions, i.e., 19 divided by 2 would produce a real world answer of 9½, but we would ignore the remainder or fractional ½.

4. Any division that produces an EVEN number gives us a ZERO in our process of converting decimal to binary.

5. Any division that produces an ODD number gives us a ONE in our process of converting decimal to binary.

6. The process of successive divisions ends when the number is finally reduced to ONE again, ignoring any fractional remainders.

Example: Convert Decimal Number 38 to Binary

1. By inspection, since 38 is an even number the least significant bit is a ZERO.

.....0

2. 38 divided by 2 = 19. Nineteen is ODD, hence next bit is a ONE.

....1 0

3. 19 divided by 2 = 9 (ignore fraction). Nine is ODD, hence next bit is a ONE.

...1 1 0

4. 9 divided by 2 = 4 (ignore fraction). Since 4 is even, next bit is a ZERO.

..0 1 1 0

5. 4 divided by 2 = 2. Since 2 is even, next bit is a ZERO.

.0 0 1 1 0

6. 2 divided by 2 = 1 (divisions end). Since ONE is ODD, the next bit is a ONE.

1 0 0 1 1 0

The final binary number thus produced is decimal 38 converted to its binary form.

This painless method makes it much easier to generate decimal to binary conversions than remembering the absolute values of each binary bit, particularly for conversions where the decimal number is four or five digits long.

Decimal to octal conversion is a similar process involving successive divisions by eight. However, the signposts in the divisions are different. In the decimal to binary conversion we completely ignored the fractional parts associated with the successive divisions. In the octal conversion we use the numerator of these fractional parts to tell us what the octal bit values are to be.

As you know, in binary or base two, we only have a string of ONEs or ZEROs in the final conversion. In octal or base eight we use the numbers ZERO through SEVEN.

*How the Hell does it Work?
**Somewhat Volatile Memory (mine).

Decimal to Octal Conversion

1. As in the binary conversion, we are using a series of successive divisions; this time the constant divisor is 8. The same rule of bit value applies: Rightmost digit is the least significant bit and the leftmost digit is the most significant bit.

2. Select a number in decimal to be converted to octal and divide it by 8. This will result in a whole number or a whole number plus a fraction. If the result of the division is a whole number, the octal bit is a ZERO.

3. If the division results in a whole number plus a fraction then the octal bit is represented by the numerical value of the numerator of the fractional part.

4. The next successive divisions divide the whole number part of the previous division by 8, applying the above rule for determining the bit value of the octal number.

5. The successive divisions come to an end when you are left with a simple fraction.

Example: Convert Decimal 525 to Octal

1. 525 divided by 8 = 65-5/8. Thus our least significant bit is 5.

. . . 5

2. 65 divided by 8 = 8-1/8 thus our next bit is 1.

. . 1 5

3. 8 divided by 8 = 1-0/8. Since ONE is a whole number the next bit is a ZERO. The form 1-0/8 is shown to make it clear that the numerator is really still our guidepost even in the case of "no" fractional remainder.

. 0 1 5

4. We now divide ONE by 8 (which equals 1/8), which produces our most significant bit – and the division process ends as we are down to a simple fraction.

1 0 1 5

Thus 525 decimal has been converted to 1015, which is its octal equivalent.

These simple conversions will make life a bit more livable when you meet the computer, and you are a giant step ahead of good old Flavius Maximus, who had to MCXVII it all the way to the Circus Maximus checkout. By the time he got his change counted, the show was over! ■

The Smart Power Supply

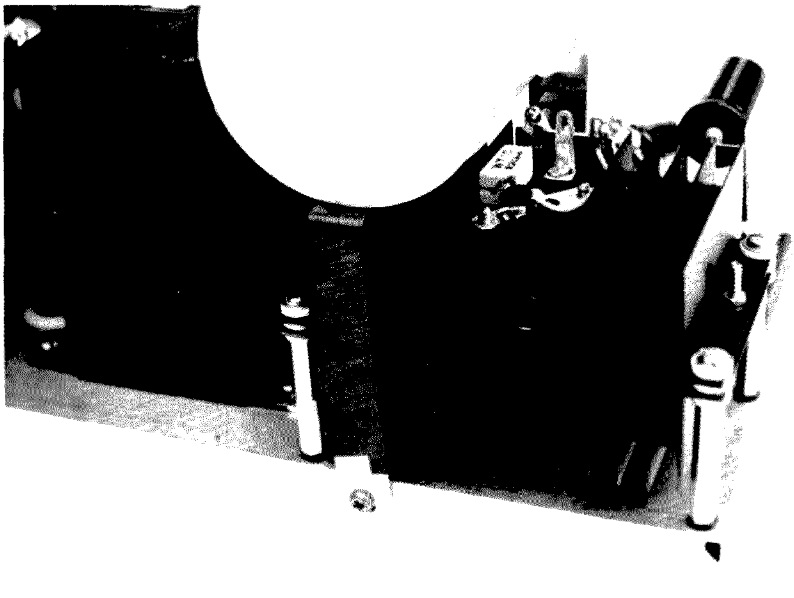
The need for a good, laboratory grade high current power supply prompted the design of this continuously variable current and voltage regulated supply for general bench use. Various parameters were considered with an eye to size, cost and simplicity. It was decided to design a 0-20 Amp, 0-25 volt regulated supply with an additional regulated 5 volt, 10 Amp logic output for experimenting with high current TTL circuits.

A Motorola chip MC1466 is available for \$7.50 from most IC distributors. This basically is the heart of the power supply. The chip continuously monitors the voltage/current requirements and provides an output proportional to the various parameters as set by front panel controls. This output is fed to some pass transistors to boost the current to the required level. All the regulator parts are mounted on a PC card with the exception of the 2 pass transistors and their emitter resistors.

With this design, any voltage/current relationship may be employed, the output depending only on the maximum ratings of the 2 pass transistors and the transformer/rectifier used. It would not be unrealistic to use this same circuit but with a different transformer to provide a 0-50 volt, 30 Amp supply, or by changing both transformer and pass transistors a 0-500 volt, 2 Amp supply. The chip is quite versatile, maximum current and voltage output being determined by the value of the voltage and current adjust pots. For maximum output, 1 mA must flow through pins 3 and 8 of the IC. Therefore, for a 25 volt supply, this value is 25k. For a 50 volt supply, it is 50k. As long as the voltage from the rectifier is 2 volts or so above the maximum value required, the finished unit will exhibit voltage and current limiting to the required maximum limits.

The circuit is straightforward and simple. An auxiliary supply, 20 to 30 volts at 20 mA, is required for operation of the MC1466. A Calrad or similar Japanese transformer rated at 26.5 volts at 80 mA was used with a simple on-card half wave rectifier and filter capacitor. The main dc supply is obtained from a Signal Transformer Company 18-12 transformer. This transformer has two center-tapped windings rated 18 volts at 12 Amps. Paralleling these windings and utilizing a bridge rectifier gives a maximum 25 volt, 24 Amp output from the supply. Transient and noise protection to the IC is necessary and is accomplished by C_1, C_2, C_3, C_9, C_{10}, C_{11}, R_1 and D_3. The capacitors equalize high frequency components across the main and auxiliary supplies while the resistor and zener diode shunt transient spikes around the IC.

A range switch switches the transformer secondary taps to keep from wasting power. When up to 10 volts or so is needed, this switch controls a relay which is hooked to



Heat sink and capacitor (C15) mounting. Unregulated voltage from the bridge rectifier assembly is attached to one of similar screws at each end of heat sinks. 2N3055 pass transistors are fastened to heat sinks. The .10 Ohm resistor in view was used in prototype, but higher current supply as described in text must have two each.

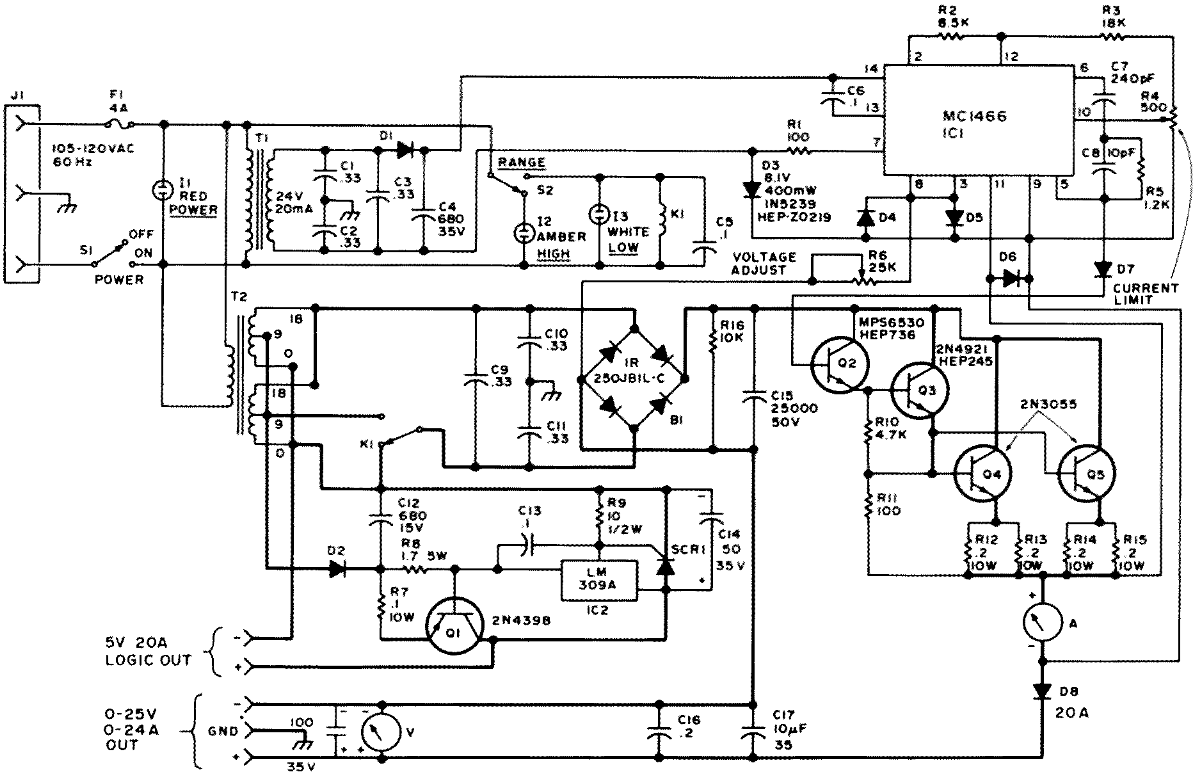


Fig. 1. Schematic. Note: All resistors ¼ Watt except where noted. All diodes 1N4002 or equivalent except D2, D3, D8. D2, D8 are 50 piv 20 A. Dark lines indicate #12-#14 wire or heavier. All other wiring #18.

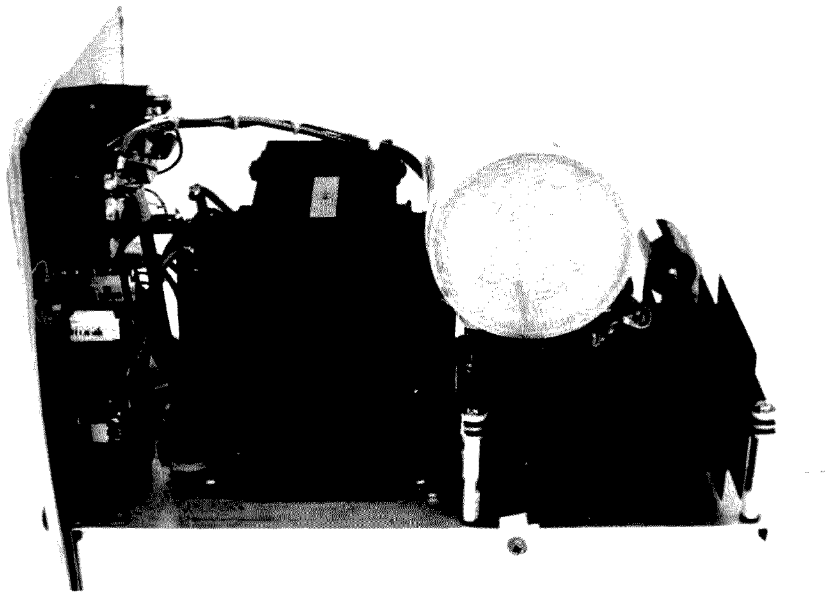
the 0 and 9 volt taps on the transformer. If higher voltage is needed, it must be placed in the high position which utilizes the full secondary of the transformer.

Since cost was a factor, inexpensive Japanese meters were used. They are accurate to within 4% of full scale. With respect to voltage, this is a mere one volt. When checked against DVOM, they were found to be well within this accuracy.

The bridge rectifier used was an IR 250 JBIL-C, rated at 25 Amps, 100 piv. Since this is an integrated bridge rectifier configuration designed to be mounted on a single heat sink, it was used to save the space four discrete mount rectifiers would require. Note that an adequate heat sink is required (IR HE 510).

After filtering, the 25 volt output from the main supply is fed to the pass transistors and the regulator card. The pass transistors are two 2N3055s in parallel for current requirements mounted on two IR HE513 heat sinks. The collectors must be insulated from ground since they are connected directly to the unregulated dc output from the filter. The IR heat sinks have insulated mounting bushings which preclude the use of mica transistor insulators and thus provide better heat sink action. The four 0.2 Ohm resistors (R12-R15) equalize the emitter loads and allow for differences in



Side view of supply.

Method of mounting capacitor C15 (25000 uF). Large cable ties strap it to heavy aluminum bar, bent to fit chassis. Heat sink to left contains 10 A 5 V logic regulators. Small capacitor beneath is C12; C13 is visible attached to LM309 socket. R16 is attached to C15 terminals.

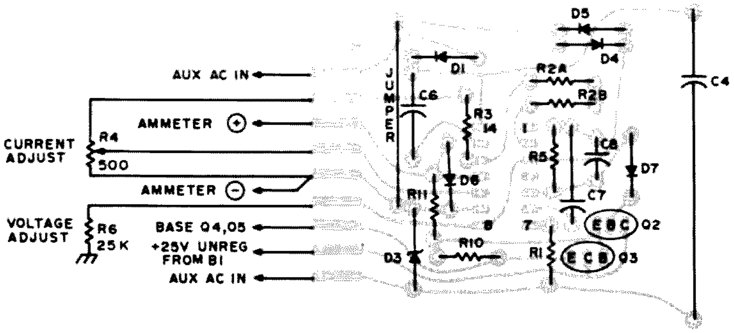

Fig. 2(b). Component layout.

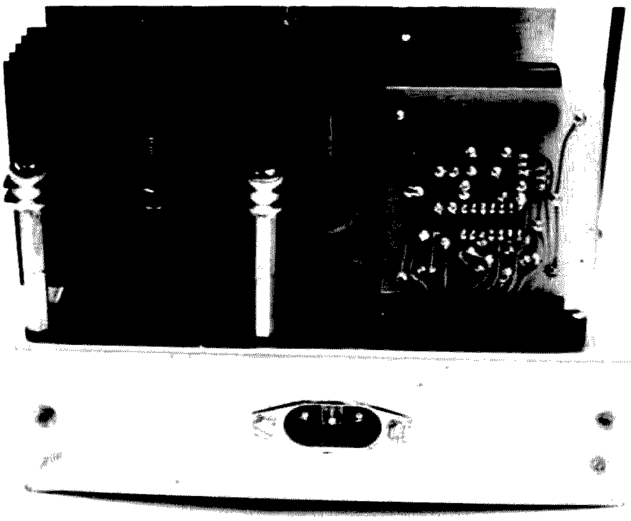
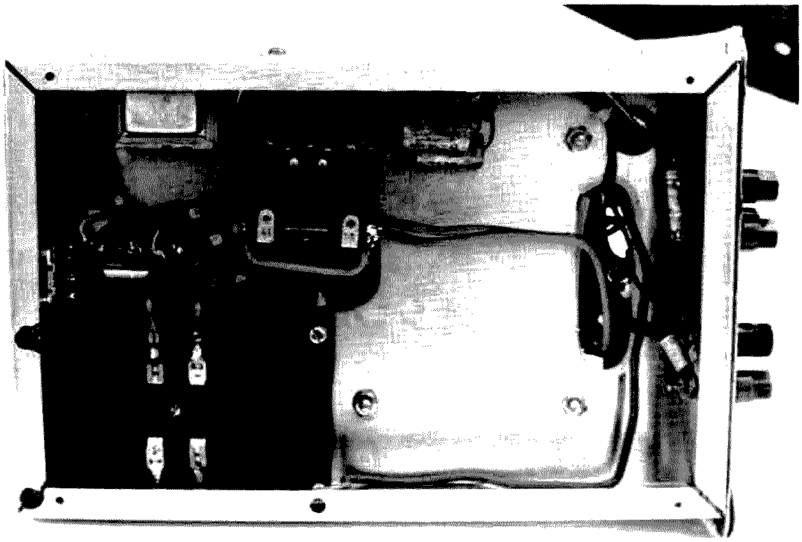


Rear view of power supply showing PC board and heat sink mounting (for pass transistors). PC board contains all regulating parts except for pass transistors.

individual transistors. At full output, each parallel leg passes 10 Watts. Thus 2 resistors at .2 Ohms, 10 Watts in parallel are hooked to the emitter of each transistor to give a .1 Ohm, 20 Watt resistor. A terminal strip is fastened to the heat sink for the other end of these resistors by tapping out a 6-32 hole in the heat sink and mounting the terminal strip so that the resistors fit snugly along the channels of the heat sink.

This method helps keep the resistors cool and makes for a neater layout. After connecting these terminal strips together with heavy wire, another length of 12 or 14 gauge wire is run to the current meter. Note that if this meter is not used, a .025 Ohm, 15 Watt resistor must be used across diode D3 (or 4 0.1 Ohm, 5 Watt resistors). Also diodes D4, D5 and D7 must be used if your input voltage is above 20 volts, for protection of the chip during short circuit or transient conditions. Additional protection is insured by D6 in the case of simultaneous pass transistor failure and output short circuit, and D8 protects the power supply in circuits with a high ac content which could damage the IC.

The logic supply consists of an LM309 and 2N4398 (or equivalent) shunt transistor to provide a fixed 10 Amp, 5 volt regulated supply for logic designs where high current TTL is used. The 0 and 9 volt ac taps from the power transformer are used for primary input power. This is rectified in a simple half wave circuit and filtered with C12. C13 prevents oscillations from lead dress or other factors evident in some of these surplus 309s. The LM309 then provides the control and protection circuitry for the entire circuit. Current limiting is achieved by limiting the base drive to the PNP transistor under short circuit conditions. The internal current limit for the LM309 is approximately 3 Amps. Under short circuit conditions, this causes about a 3.4 volt drop across R8, one Amp being needed to drive the base of the transistor. Assuming a 1 volt VBE for the 2N4398, the peak output current is then limited to about 10 Amps. The transistor and LM309 are mounted on a common heat sink allowing the thermal limiting circuitry of the IC to protect both the power transistor and regulator in case of excessive dissipation. Additional protection is achieved by the SCR and R9. If the output rises above 5 volts, the internal zeners in the LM309's output conduct, greatly increasing the ground pin current. When the output approaches approximately 7.5 volts, the SCR will fire, thereby shutting off the over-voltage and protecting the circuit under test. Under normal conditions, only about 50 mV is dropped across R13. Since the 50 Amp SCR is expensive, this is not a necessary addition. If this is omitted, however, the 10 Ohm resistor R13 should be shorted. This crowbar circuit is effective and is good over voltage protection, however, since the 5 volt supply is not metered.



Bottom view of chassis, showing PC board socket wiring, relay placement, and rectifier and heat sink location.

The whole circuit is built into a Bud WA1541 portacab on a Bud AC407 chassis. This cabinet has a handle on the top for easy carrying and is usually found at hamfests, sans front panel which can be easily made. The front panel layout is included in Fig. 3 for photo layout on Scotchcal® or other panel materials. The 2N3055 transistors are mounted on heat sinks which are placed bottom to bottom so that the mounting flanges are closest to each other. After the 2N3055s are mounted and R12-R15 installed as previously stated, a hole is drilled through the center of each heat sink flange and a 6-32 screw with a 6-32 nut, used as a spacer, on each holds the heat sinks together. The main supply connects to one of these screws. The insulated bushings supplied with the heat sinks are secured in place and the whole assembly is mounted on the right rear corner of the chassis using threaded spacers. Directly underneath these heat sinks on the inside of the chassis, the heat sink for the 25 Amp bridge rectifier is secured through the chassis to the threaded spacers. A hole is drilled and tapped in the bridge heat sink to accept an 8-32 screw, which secures the rectifier assembly. The use of silicone grease is recommended to insure adequate heat sinking. Since the IR 250 JBIL-C rectifier is insulated from ground, no mica insulators are needed.

The PC card is designed for a Cinch 50-10A-20 board edge connector. This connector is fastened through the left rear of the chassis and wired. Directly in front of this is another heat sink for the LM309 and 2N4398. The front half of the chassis is reserved for the main power transformer T2. Underneath, the auxiliary supply transformer T1 and relay K1 are located. Filter capacitor C15 is a 25000 microfarad 50 volt unit obtained surplus. It is so large physically that it had to be mounted to a piece of steel bracket bar ½" wide, which was bent to go up, over and down past the pass transistors and other heat sinks on the top. It is then fastened to the chassis sides and the capacitor held in place with large wire ties. The photos show the layout of the larger parts.

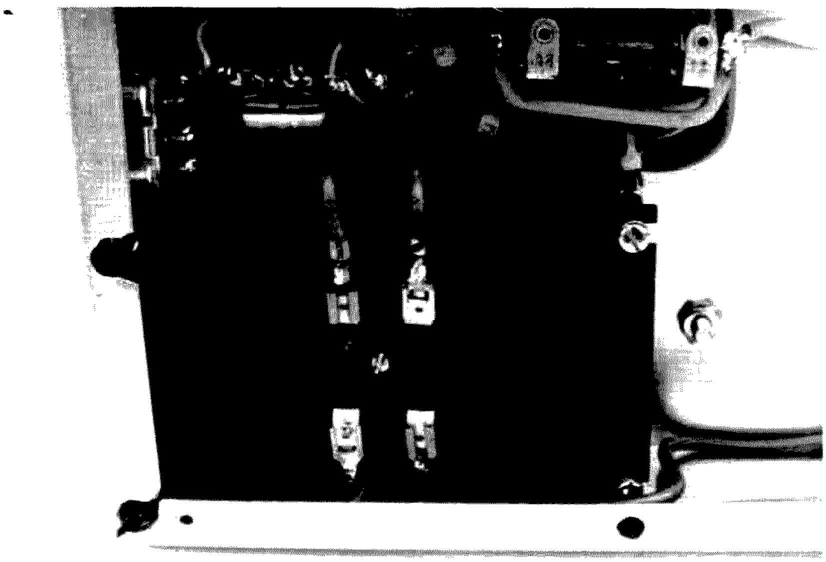
Substitutions are no problem. The pass transistors can be any high current types. The others can be any substitutes, keeping in mind that an F_t of $>$ .5 MHz is desirable. The diodes, except for D2 and D8, are all 1N4002 or any 1 Amp garden variety plastic diodes. If the space is available, the IR bridge assembly may be converted to 4 discrete diodes wired in a bridge configuration but with adequate heat sinks. D2 and D8 are 20 Amp diodes heat sinked to the chassis. The main transformer, as stated previously, can be any voltage desired, not to exceed the Vce ratings of the pass transistors. Similarly, the current ratings can be 2 Amps or 200 Amps, making sure, again, that your chosen pass transistors will handle it. Relay K1 is a surplus 110 volt DPDT unit with 15 Amp contacts wired in parallel.

After construction, check the unit out by placing it on its side and setting the controls as follows:

Voltage Adjust	Fully ccw
Current Adjust	Nine o'clock
Range Switch	Low

Turn the unit on and make sure the "low" and "power" lights come on. Set the range switch to high and check its indicator. Then rotate the voltage control until the voltage meter reads 10 volts. Rotating the current limit pot fully ccw, the voltage will fall to zero. Next connect the 0-25 volt terminals together and carefully adjust the current limit pot until the current meter reads 2 Amps. Let this condition remain for a few moments to check for signs of overheating. Next, a 10 Ohm, 10 Watt resistor should be placed across the output which will indicate a current of one Amp. Watch the voltage meter for signs of fluctuation while hooking this up to check the regulating circuits. A small drop may be evident which will be as a result of I^2R losses in the wiring and current meter.

Do these steps in exactly the above manner if you are not sure what you are doing. If all seems normal, disconnect the load and rotate both voltage and current adjust pots to max and watch the meters. Throw the range switch to low and assure that the voltage drifts to about 12 volts with no load.



Close-up of 250JBIL rectifier bridge and heat sink assembly, showing method of mounting and wiring.

If all seems normal, install in the cabinet using the 4 panel mounting screws. Next, place it on the rear end and drill out the chassis flanges to accept #8 self-tapping screws, and affix rubber feet through the cabinet to these holes. Do not rely on the 4 panel screws because of the weight of the transformer.

The prototype has been in use for the last three months and has been found to be reliable and trouble free. The power supply exhibits a low impedance at all frequencies and low noise. It has been used at full output to service a 100 Watt Class C amplifier being driven by a 10 Watt transceiver, as well as a low current automobile tape deck, and performed equally as well on both set ups. It was a pleasure to set the voltage output to 13.5 volts, key the transmitter and amplifier and watch the output remain constant in spite of the increased current, a fact not before possible when unregulated, variac controlled power supplies were used. Charging batteries is another use to which this has been put. A constant charge rate is easy to achieve by setting the voltage to anything over what the battery is rated and setting the current flow to the desired rate. ■

FOR YOUR EYES ONLY

Guidebook of Electronic Circuits
by John Markus
McGraw-Hill, Inc. ($24.50)

This is one of the most comprehensive collections of electronic circuits available, and it will save you much time in finding that special circuit for your next project. Here in one volume are over 3600 diagrams of the most widely sought, yet difficult to obtain, electronic circuits. This book is a rich collection of circuits from amateur radio magazines (including *73*), books, application notes and hundreds of other electronics magazines.

All diagrams are arranged in a manner which makes it easy for the amateur, student or engineer to find exactly what he's looking for in a matter of minutes. In addition to the table of contents (arranged in 131 alphabetical classifications), there is an author index – as well as a subject index with over 10,000 entries to help you find the exact circuit you need.

As an example of the sections, here are just a few of the 131 categories presented: alarm circuits, amplifiers, A/D converters, audio, automotive, battery chargers, clock circuits, computer circuits, counters, digital display circuits, filters, hobby circuits, lasers, measuring circuits, metal detectors, multiplexers, op amps, oscillators, photography circuits, receiver circuits, regulators, remote control, science fair projects, stereo circuits, telemetry, telephones, television circuits, test circuits, transceivers, transmitters, VCOs, zero voltage switching circuits – and the list goes on and on.

In addition, all circuits described are fully tested with component values listed to assist you in duplicating the results.

Information for the book was drawn from a multitude of sources and the following quote by the author verifies this:

"The circuits for this new book were located by cover-to-cover searching of back issues of U.S. and foreign electronic periodicals, the published literature of electronic manufacturers, and recent electronic books, together filling well over 100 feet of shelving."

Now that you have some idea of the wealth of information contained in this single, easy-to-use volume, I'm sure that you will want to own your own copy. I highly recommend it.

W. J. Prudhomme WB5DEP

Electronic Projects for Musicians

This is a dandy book, written by one of *73*'s authors, Craig Anderton. It runs about 134 pages and sells for $6.95. If you are into music you'll really get a kick out of this one. There are very simple projects for building all sorts of fantastic music gadgets . . . particularly for electric guitars or amplified guitars. Fuzz, ring modulator, treble booster, all kinds of special effects. If you're not into the guitar, you might be into making money as a builder of music gadgets . . . looks like a very profitable field.

The book is written for the absolute beginner, and there are several chapters about the parts, building, switches, knobs, wire, hardware . . . a very good basic introduction to home building which any Novice would do well to read.

To get the book, complete with a record built in demonstrating the effects of the gadgets, send $6.95 to Guitar Player Productions, Box 615, Saratoga CA 95070.

Master Handbook of 1001
Practical Electronic Circuits
Edited by Ken Sessions
Tab Books No. 800
$9.95

Here is a different approach to a radio and electronics handbook. The *Master Handbook of 1001 Practical Electronic Circuits* is a valuable reference tool, containing schematic, logic, and block diagrams for scads of electronic goodies.

There are circuits for alarms and automotive circuits, power supplies and regulators, timers and test equipment, transmitters, receivers, and lots more, each section including simple and complex circuits. The collection is well organized and indexed. You can use the handbook to help you design equipment, or simply build the circuits directly.

Modern digital IC circuitry is presented, with both large-scale integrated circuit diagrams and "discrete" logic diagrams that clarify what goes inside the "black boxes." An appendix gives IC substitution data.

Adrift Over Your C's?

by
F. G. Rayer G3OGR
Reddings, Longdon Heath
Upton on Severn, Worcs.
WR8 ORJ, England

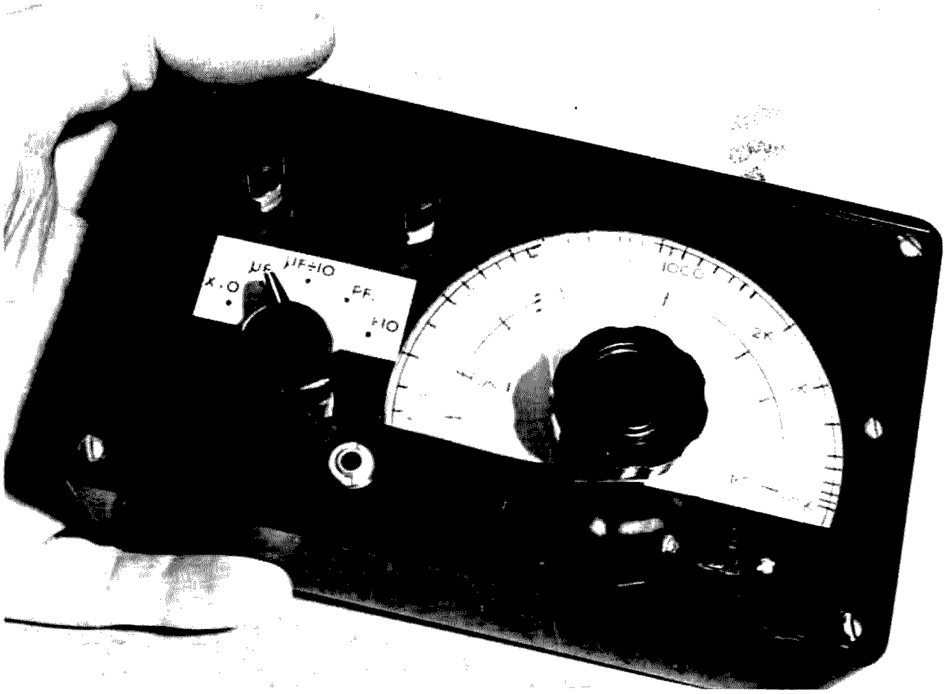
Once upon a time capacitors were nicely marked 0.1 uF, or even 0.05 MFD, or so on, as the case might be. But now it is necessary to deduce their value from a rainbow of bands or spots, not to mention such numberings as 4k7, 5n, 5pj. Is that last colored band a figure in the value, or a tolerance? Not to mention the useful collection of mica and other capacitors with obliterated markings, and those with only a maker's number. Having recently used some quite large tubular capacitors marked 5kp, in the expectation that they were 5,000 pF, or 0.005 uF, only to find they were in fact 50 pF, I decided it was high time a simple means of checking the values of doubtful capacitors was made.

The circuit of the result is shown in Fig. 1, and despite its simplicity it works nicely for values from 25 pF to 10 uF. Q1 and Q2 are combined to form an audio oscillator, output from Q1 being applied across the bridge.

The bridge has five capacitors, for five ranges. Cx is the unknown capacitor. VR1 is a linear pot (it must be linear) for balancing, and high resistance phones indicate the null, so that the capacitor value can be read from the setting of VR1.

Oscillator

Assembly details will probably not matter much, but the audio oscillator can be wired on a tag strip, as seen in the photo. Both the



transistors are audio or small output types, such as are available in great number, and it is difficult to find two transistors which will not work here. Q1 must, however, be NPN, while Q2 is a PNP type.

A quite high tone is best, and if necessary juggle with C6 or R2, or both, to obtain this. The supply need not be 9 V. The phones put across R1 will show how this works, and two flying leads are soldered on to go to the bridge part of the unit.

Bridge

The 5-way switch selects any capacitor C1 to C5. Without using the extreme settings of VR1, where accuracy falls, the center setting of VR1 is obtained when Cx is the same as C1, C2 or so on. As an example, if C3, 0.01 uF is in circuit, the middle setting of VR1 balances the bridge at 0.01 uF for Cx. From here, the swing of VR1 goes from one-tenth to ten times, so that this range is 0.001 uF to 0.1 uF.

In the same way, C2 (1000 pF) gives a range of 100-10,000 pF, while C4 gives 0.01-1 uF, and C5 gives 0.1-10 uF. C1 would by the same token provide 10-1000 pF, but the null or balancing point for VR1, easily audible with larger values, grows a little difficult to hear at the extreme low capacitance end of this scale.

It will be seen that the overlap is such that the same total coverage would be achieved with only C1, C3 and C5. These three ranges would be 10-1000 pF, 0.001-0.1 uF, and 0.1-10 uF. However, the extra capacitors C2 and C4 are well worthwhile, to fill in for easy checking.

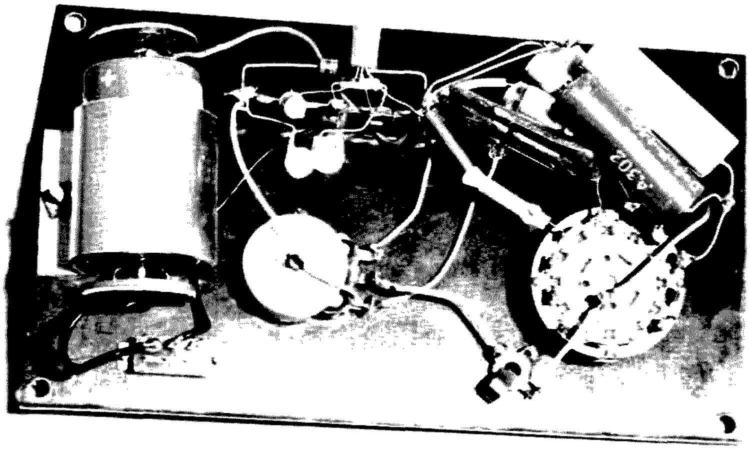
C1 and C2 should be silver mica 1 percent items. For C3, a 2 percent or 5 percent item will probably have to be adopted. C4 may be difficult to get with better accuracy than 10 percent, unless costly, while C5 is actually two 0.5 uF tubulars in parallel. This means that calibration can be accurate for the lower values, but is less so for high values. In any case much accuracy is often not necessary with large values, except possibly in audio filters and some other applications.

These items are grouped mainly round the switch, and the layout shown allows convenient wiring with the capacitors supported by a near tag of the audio oscillator section.

Case Etc.

A plastic box about 6 x 4 x 2 inches with insulated panel is most suitable. It carries an outlet for the phones, on-off switch, two terminals for Cx and a bracket to clamp the battery in position.

The scale for VR1 is marked 100 pF to 10k pF for C2 range, and 0.01 uF to 1 uF for C4 range. The switch is marked pF and



Interior view.

uF for direct reading of these ranges, and for uF x 10, uF ÷ 10, and pF ÷ 10 for the other ranges.

Calibration is carried out on the C2 range, with several known capacitors, perferably 1 percent, such as 100 pF, 250 pF, 500 pF and a few others. Values can be obtained by paralleling some, such as 250 and 100 for 350 pF, while switching to C1 range allows the 100 pF, 250 pF and other low values to be used again, for what will be 1000 pF, 2500 pF and similar 10x values on the C2 range.

No calibration is made for the large capacitor ranges, as these will be progressively 10x the existing ranges (assuming C3, C4 and C5 are accurate enough).

A clip or two on short leads from the terminals will be handy for some capacitors. Simply rotate VR1 for the null, and read the value on the scale. High impedance phones, in the 2k to 4k range, will be best. A dip but no real null shows leakage, and is to be expected with electrolytic capacitors. ■

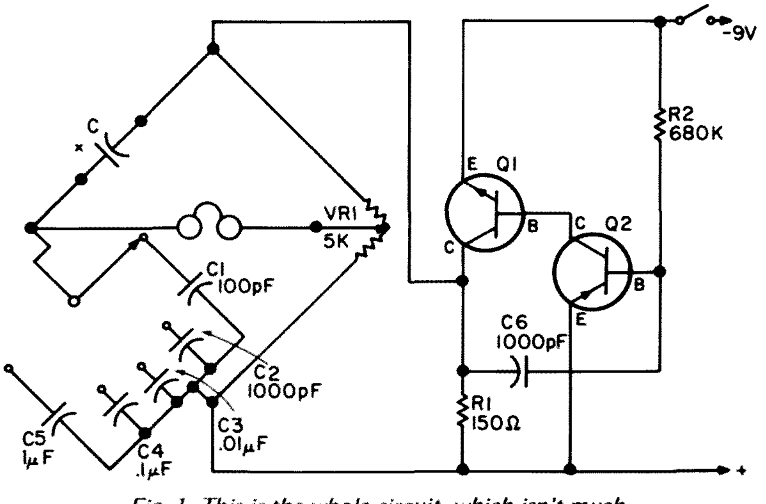


Fig. 1. This is the whole circuit, which isn't much.

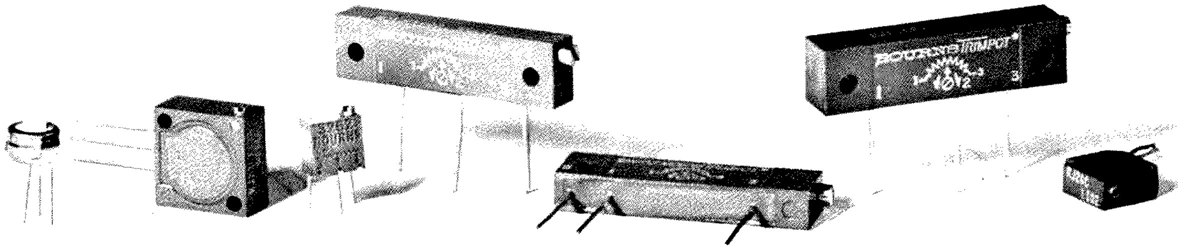
How to Use Surplus Pots

by
Robert W. Fay WB0NPN
4201 Briar Park
Lincoln NE 68516

There are many good buys in potentiometers to be found on the surplus market. Some of these are of the adjustment and precision types, forms of pots that are precisely settable and manufactured to exacting specifications. This article will describe basic characteristics of adjustment pots, methods for identifying usable units and simple tests to make sure they are functioning properly.

A potentiometer is a variable resistor used to adjust voltages in electronic circuits. It is composed of a



resistive element, whose total resistance is the value used for identification purposes. A current flows through the resistance creating a voltage drop across the resistor, and a movable wiper contact is driven from one end of the resistance to the other, thereby tapping the resistance to obtain the desired voltage.

Adjustment potentiometers are made by several major electronics components manufacturers. Surplus circuit boards often contain pots of varying styles and resistance, thereby offering a variety of additions to the junk box.

The most common type of pot is the single turn panel mount used for repetitive adjustment purposes such as volume, squelch, etc. These are turned with a knob, screwdriver, allen wrench or the bare finger routine, and are adjusted from end to end in one turn or less.

Precision pots are also panel mounted and knob adjustable. However, they are made of multiple turn design which permits the use of a long, coiled resistance element. As the pot is adjusted, the wiper spirals along the coils permitting great precision and settability. Precisions are often mounted with a clock or digital readout dial, thereby allowing exact resetting.

An adjustment pot operates on a screw and gear reduction principle, with multiple revolutions of the adjustment screw being required to drive the wiper from one end of the resistance to another. Since they have a shorter resistance

Style	Resistance-Temperature Characteristic	Temperature Characteristic	Terminals	Resistance	Failure Rate
Wirewound RJ24	C	2	P	101	
Non-wirewound RJ24	F		P	101	
Established Reliability RTR24	D		P	101	M
RJR24	F		P	101	M

Table 1.

element, their precision falls between the multi-turn and the panel control. Additionally, most adjustment pots contain a clutch mechanism at the end of wiper travel to prevent internal damage, which could result due to the mechanical advantage of the gear reduction system. Leadscrew versions are driven linearly with a machined leadscrew, in the same manner as the tool holder of a lathe. Worm gears have the resistance element formed in a circular manner, and contain a worm driving a gear to produce the circular motion of the wiper. Space, mounting requirements, electrical specifications and function are the prime determinants in the selection of which type to use.

The most common types of pots have resistance elements made of carbon, cermet, conductive plastic and wire. The carbon pot is most often found in panel mounting controls. They are made by depositing a carbon based resistance compound on a dielectric mandrel. Carbons can be made in very high resistances, have a negative temperature coefficient, and tend to absorb moisture.

The cermet pot is made by printing a proprietary suspension on a ceramic substrate. This type is rapidly replacing the carbon pot due to superior electrical and mechanical performance, plus manufacturing cost advantages. They withstand elevated temperatures, offer long mechanical cycle life and infinite resolution.

Conductive plastic is quite similar to cermet, and represents the latest development in pots. The resistive ink is chemical in nature rather than a suspension.

The wirewound pot is made by winding a very small diameter wire on a dielectric

or insulated mandrel, which is then formed to fit within the configuration of the finished unit. The resistance per foot of the wire is translated into the number of turns of wire required to produce a predetermined total resistance for a given diameter and length of element. Destructive analysis of a 10 Ohm and a 50k Ohm wirewound would show much larger diameter wire more widely spaced in the 10 Ohm than in the 50k. The wire in the 50k will actually be smaller *in* diameter than human hair.

Generally speaking, wirewound pots are used in applications requiring high power handling capability, stability of setting, and low temperature coefficient characteristics. Carbons, cermets and conductive plastics permit infinite resolution, stability of setting, better high frequency performance than wirewounds, and are available in a very broad range of resistances and tapers. They are lower in cost than wirewounds.

Before we go further into identification and testing, let's look at definitions for some of the terms already used and those to come later. These are the most common terms affecting the casual user.

Resistance (Ohms)	Code
10	100
20	200
50	500
100	101
200	201
500	501
1k	102
2k	202
5k	502
10k	103
20k	203
50k	503
100k	104
200k	204
500k	504
1 Meg	105
2 Meg	205
5 Meg	505

Table 2. Resistance Codes.

Total Resistance (TR): The resistive value in Ohms of the entire pot. Omitting the variable wiper tap, the pot could be used as this value of fixed resistor.

Resistance Tolerance: The variation from nominal value in Ohms, usually specified as a percentage. A 50k Ohm unit with a tolerance of ±10% could have a value between 45k and 55k.

Power Rating: The power in Watts which the pot is capable of dissipating at a specified temperature. Use Ohm's law to calculate the power dissipated in a particular situation. The power dissipation capacity will be reduced at elevated temperatures.

Maximum Operating Temperature (MOT): The highest temperature at which the pot is rated to function.

Higher temperature, either internal or ambient, may result in electrical characteristic changes, and/or electrical or mechanical failure.

Resolution: The minimum change in resistance that can be obtained in adjusting the pot. It is infinite in the case of a continuous strip resistance such as the cermet. In a wirewound, it is dependent upon the number of turns of wire that are in contact with the wiper, and the change in resistance per turn of wire.

Contact Resistance Variation (CRV): The change in resistance seen by the wiper circuit attributable to the movement of the wiper. It is specified as a percentage of the total resistance. This can be demonstrated by connecting a wiper to the vertical amplifier of an oscilloscope. Using a slow horizontal sweep rate, turn the adjustment screw at a constant rate. This will produce a slanted trace which shows the voltage drop seen by the wiper from one end of the resistance to the other. However, at the instant the screw is started and stopped, there will be a sharp vertical deflection of the trace. This represents the added resistance in the circuit caused by the movement of the wiper over the resistance material. Special circuits can also be constructed to show the short time duration spikes which occur during adjustment. A storage scope is of great use in this testing.

Minimum End Resistance: The smallest resistance obtainable when measured between a TR pin and the wiper, with the wiper driven to the end of its mechanical travel. It is expressed as a percentage of total resistance, or in Ohms. Ideally, it is zero Ohms, but in practice will not reach this value due to contact resistance within the pot or physical factors of construction.

Nominal Turns Adjustment: The average number of revolutions of the adjustment screw needed to drive the wiper from one end of the resistance to the other.

Temperature Coefficient: The change in resistance per degree change in temperature, expressed in parts per million (ppm). Typically, the temperature range is $-55°C$ to $+150°C$.

Taper: A term describing the change in resistance per unit advancement of the wiper. The taper is linear when the change in resistance is uniform with respect to wiper advancement. Just about any taper can be made.

Mil-Spec Humidity Requirement: Mil-Spec units must pass a humidity test. This insures that they will

operate satisfactorily in a wide variation of ambient conditions, and may be successfully post coated after assembly to the circuit board. Will be stated as yes or no in the specification sheet.

Noise: A discontinuity between the wiper and resistive element experienced as the wiper is driven along the resistance. It would be observed in the same test set up for CRV as a sharp vertical deflection or discontinuity on the scope. Manufacturers establish QC criteria relating to permissible voltage variations and time durations. Everyone has experienced this in the extreme form of a noisy volume control.

DESC: Defense Electronic Supply Center. The agency which sets Mil-Specs for all electronic components, and verifies performance to these requirements.

Qualified Parts List (QPL): A listing of manufacturers qualified by test and performance verification to produce potentiometers listed in the Mil-Specs. Letter designators are listed on the pot to indicate the level of qualification (number of successful hours of testing without failure exceeding prescribed limits).

When you obtain a surplus pot, you will find it marked with either the manufacturer's model number or the Mil-Spec designation. In some cases both the Mil-Spec designation and the manufacturer's model number may appear on the pot. In this case, it is obvious that the manufacturer uses the same basic design to fill both markets, although the exact specs and quality control testing for each group may be different. It should be noted that Mil-Spec requirements are minimums that a pot must meet. It is possible to exceed these requirements in regular production.

A manufacturer introduces any model potentiometer for which he feels there is a market. However, in the case of Mil-Specs, there are only certain model classifications. These relate to physical size, type of resistive element, and electrical/mechanical specs. This permits standardization

Table 3. Key to terminal types.

Type	Description
J	J Hook Solder Lugs
L	Insulated Stranded Leads
S	Solder Lugs
P,T,Y	Printed Circuit Pins (flat mtg.)
W	Printed Circuit Pins (edge mtg.) with screw parallel to pins
X	Printed Circuit Pins (edge mtg.) with screw at right angles to pins
Y	Printed Circuit Pins (staggered — flat mtg.)

Qualification Level	% Failures per 1000 hours load life test
M	1.0
P	0.1
R	0.01
S	0.001

Table 4. Key to failure rates (established reliability).

within the military electronics market.

To be listed on the QPL for a given designation, a manufacturer must produce pots which will meet all of the applicable Mil-Specs, in test conditions supervised by DESC. Once listing on the QPL is obtained, the manufacturer must periodically retest production units in each designation to insure continued compliance. Additionally, there are different levels of qualification which relate to the total number of hours test units have been functioning under specified electrical load conditions without failures exceeding a set rate. The qualification level, as we will see later, is marked on each Mil-Spec unit. Most manufacturers also conduct a similar program of recertification for their own models.

Each potentiometer model is manufactured in several different mounting configurations. This permits the utmost flexibility for the circuit board designer. Basically, these involve the orientation of the adjustment screw with respect to the terminal pins, the spacing and shape of the pins, and the physical dimensions of the pot. It is also possible to buy pots with wire leads, thereby permitting mounting of numerous assemblies at a location convenient for service adjustment. Rarely will the operating characteristics of the same model vary between pin styles.

Now that we have the basics down, let's pick up a pot and learn how to identify it. We'll start with some Mil-Spec units, which are the most often encountered type.

Tables are included to explain the coding. The breakdown between wirewound and non-wirewound is evident, together with the additional R in the established reliability group. Each type will also have a date code, such as "7426A." This means the twenty-sixth week of 1974, and the letter indicates manufacturing plant location, which can be obtained from the QPL.

See! 73 BICENTENNIAL SUBSCRIPTION AD p.19

There is another grouping of Mil-Spec pots known as the Established Reliability group. These are upgrades of the regular DESC models, and must continually pass the most exacting tests. Table 4 contains an explanation of the failure rates.

All pots also have an electrical schematic printed or molded on them. This enables you to mount the pot correctly and know which way to turn the adjustment screw for the desired effect.

Were you to obtain the same pot produced as the manufacturers' model, it would be labeled as "3290-1-101," or in the non-wirewound, "3292P-1-101," in the case of Bourns. The model numbers have been substituted for the RT/RJ, -1 indicates it is the normal production version of this model, and P and 101 have the same meaning as in the DESC version. Some pots may also have the resistance printed in plain language.

Pots are often made with special characteristics or testing for specific customers. In such a case, the -1 would be changed to an identification number unique to that customer. Although you are apt to find such units on surplus boards, there is no way to interpret these markings, and the unit will have to be tested to determine if it is usable in your particular application. In most cases, it will be, since many of these pots have had only special testing or electrical preconditioning.

Now that we can identify what we have, let's move on to some simple tests that will let you know if the pot is usable. All of these can be performed with an ohmmeter.

Set the ohmmeter range to coincide with the TR code of the pot and measure TR by connecting to the two appropriate pins, as indicated by the schematic. Remember to account for the TR tolerance per our definitions. If you are unable to get a reading, switch the meter successively to different ranges. No reading on any range indicates an open pot, which is useless. If a reading is obtained on a different range, the pot may be misprinted, or there may be an electrical malfunction within the unit. We will see how to determine which of these is the case further along.

Now switch one of the ohmmeter probes to the wiper pin, leaving the other on one TR pin. A change in resistance as the adjustment screw is turned should be noted. If a change does not occur, the wiper is not driving, and the pot is useful only as a fixed resistor.

Continued

	Symbol	Maximum Resistance temperature characteristic (25°C)	Maximum ambient temperature at rated wattage	Maximum ambient operating temperature
Non-wirewound	C	±250 ppm	85°C	150°C
	F	±100 ppm	85°C	150°C
	H	±50 ppm	85°C	150°C
	J	±10 ppm	85°C	150°C
Wirewound	C2	±50 ppm	85°C	150°C
	D (ER Only)	±50 ppm	85°C	150°C

Table 5. Resistance-Temperature Characteristic.

Without changing the ohmmeter connections, turn the adjustment screw until the resistance indicated goes to zero. Now, turn the adjustment screw at a uniform rate until the resistance indicated reaches the TR value. If the resistance change from zero to maximum occurs uniformly with revolutions of the adjustment screw, the unit has a linear taper and is functioning properly. Watch for equal resistance changes per screw revolution, rather than uniform meter movement, since most ohmmeter scales are non-linear. Various tapers can be determined by plotting resistance change vs. screw revolutions.

If a unit whose measured TR did not agree with that printed on the case were tested in this manner and showed a sudden change in resistance under this test, we would have a defect within the pot which is causing a large resistance change at one point along the resistive element. These pots should not be used, as changes in TR with environmental or internal temperature variations may occur. Such failures can occur due to broken substrates, broken wires or numerous other failure modes. Dissection of the pot and subsequent tracking of the ohmmeter probe along the resistor would reveal the defect location.

Connect the ohmmeter lead simultaneously to all three terminals and the other lead to the adjustment screw. There should be no continuity. This test may be repeated several times while you are checking drive. Indication of continuity would mean electrical contact between wiper and screw, resulting in an electrically active screw and a potential for circuit damage or electrical shock.

The ohmmeter may or

may not be able to detect noise within the pot, depending upon time duration of the wiper discontinuity or damping of the meter. A short term deflection of the meter towards infinity is an indicator of noise. It can most readily be observed while turning the adjustment screw slowly. Unless noise extends over the entire resistance, the serviceability for amateur use is not seriously affected, since it is unlikely that the wiper would have to be positioned exactly at that point.

With the general information, definitions, tables of characteristics, and tests which we have developed, you are set to identify, test and use surplus pots. In home brew work, the choice of which pot to use in a given application usually is controlled by what is on hand more than operating parameters. I would suggest only a few guidelines.

If you are dealing with frequencies above audio, stay away from wirewounds. They make excellent inductors, with very unpredictable results. Check the power requirements which will be needed against the manufacturers' or DESC specs, and don't exceed them. By the way, the catalogs of major electronic supply houses are excellent sources to obtain the manufacturers' basic specs.

The MOT of many pots is close to the maximum temperature that internal components can stand without failure. Overloading the pot will raise its temperature, inviting failure. Choose a pin style that will fit neatly on the circuit or perf board and provide easy access for adjustment. If the pot has to be buried in a sandwich, use a wire lead model.

Adjustment potentiometers are rugged devices, so only moderate care need be exercised in mounting to circuit boards. All pots have high solderability requirements for the terminals, since they are usually wave soldered to boards. Surplus pots may show degraded solderability due to contaminants on the pins. These may be cleaned with freon or isopropyl alcohol prior to use. The flux contained in the solder core should do the remainder of the cleaning job.

As with all electrical components, there are a lot of specs that the normal user is never concerned with. I've listed only the most common ones in this article, leaving it to the individual to acquire other information if the situation warrants. Good luck and happy building using adjustment potentiometers. ■

COLLINS R-388/URR RECEIVER, military version of the 51J-3, tunes 500 kHz to 30.5 MHz, 19" rack mount, 115 V/60 Hz $345.00

COLLINS R-388A/URR RECEIVER, military version of the 51J-4, has switch for mechanical filters, tunes 500 kHz to 30.5 MHz, 19" rack mount 115 V/60 Hz 475.00

COLLINS R-389/URR VLF RECEIVER, tunes 15 kHz to 1500 kHz, digital readout, 115 V/60 Hz 550.00

R-390/URR RECEIVER, tunes 500 kHz thru 30.5 MHz digital tuning, dual rf, audio filters, 115 V/60 Hz, 19" rack mount 450.00

R-390A/URR RECEIVER, tunes 500 kHz thru 30.5 MHz, mechanical filters, 115 V/60 Hz 19" rack mount . . 650.00

HAMMARLUND SP-600JX, tunes 540 kHz to 54 MHz in 6 bands, 115 V/60 Hz, 19" rack mount 375.00

URR-13 RECEIVER, tunable UHF 225-400 MHz, used to monitor military and satellite frequencies, 115 V/60 Hz 145.00

R-109/GRC RECEIVER, 27 to 38.9 MHz FM 28 V, tunable 24.50

BC-348 RECEIVER, tunes 200-500 kHz and 1.5 to 18 MHz, 28 V, easily converts to 115 V/60 Hz by building a power supply 65.00

BENDIX MN-26C RADIO COMPASS RECEIVER, 28 V, 150 thru 1500 kHz 18.50

ARN-14 OMNI RECEIVER, 108.1 to 135.9 MHz, synthesized, complete with mount and control head 39.50

BC-733 RECEIVER, 108-110 MHz crystal controlled aircraft receiver, 28 V 7.50

ARN-5 GLIDEPATH AIRCRAFT RECEIVER, 332-335 MHz, 28 Vdc, crystal controlled 9.50

R-19/TRC-1 FM RECEIVER, 70-100 MHz 115 V/60 Hz 19.50

COMMUNICATIONS ELECTRONICS CO. TYPE 901-1 RECEIVER, tunable 30-60 MHz and 60-300 MHz in two bands, AM/FM/CW 300 kHz and 20 kHz bandwidth, S meter, 19" rack mount 225.00

PRC-6 ARMY HANDIE TALKIE, 47 to 56 MHz complete with antenna, less battery 28.50

RT-294/ARC-44 MILITARY FM AIRCRAFT TRANSCEIVER 24.0 thru 51.9 MHz, 280 channels, synthesized, 8 Watts output take 28 Vdc with control head 45.00

SG-3/U FM SIGNAL GENERATOR by Measurements Corp., covers 50 MHz thru 400 MHz in 3 bands, 01 to 100,000 M/V calibrated output fully metered, a late military type generator for FM alignment in the amateur, marine and commercial field, 115 V/60 Hz 375.00

MODEL VOX-2, Technical Material Corp., variable frequency oscillator, tunable 2 thru 64 MHz, oven controlled, 115 V/60 Hz 85.00

FREQUENCY COUNTER FR114/U, 20 Hz – 1 MHz 6 digit Nixie readout, ideal for low frequency or audio work, a scaler could be designed to operate in higher ranges to cover amateur or commercial frequencies – a beautiful counter, govt. cost $3,800.00 . . . . 85.00

ELECTRO MODEL NF FILTERED DC BENCH POWER SUPPLY, metered 0-50 Vdc and 0-25 amps dc, variable pot. Size 9½H x 14W x 14L, ideal power supply to run 12 or 28 Volt equipment, filtered for transistor work 95.00

BALLANTINE 300 AC VTVM, 10 Hz to 150 kHz range, 1 mV to 100 V in 5 ranges, logarithmic scale 1-10 dB, accuracy 2% 32.50

SG-34/GPM-15 LORAN TEST SET, use to calibrate and test all Loran a/c receivers 115 V/60 Hz 125.00

AN/PRM-1 RADIO INTERFERENCE AND FIELD INTENSITY METER, range 150 kHz – 25 MHz, sensitivity 1 mV 185.00

PRM-10 GRID-DIP OSCILLATOR, 2 MHz thru 400 MHz, perfect for antenna work 65.00

TS-175/U FREQUENCY METER, 85 kHz to 1000 MHz high frequency version of the BC-221 with original calibration book 75.00

HP-400D VTVM, a popular lab instrument, ac 1 mV to 300 V, 10 Hz to 4 MHz 69.50

BOONTON 260A Q METER, 50 kHz to 50 MHz . . 225.00

NEW LONDON 257A FM MODULATION DEVIATION METER, 20 MHz thru 1000 MHz 145.00

B & K MODEL 1075 TELEVISION ANALYST, a flying spot scanner, ideal for slow scan 135.00

TEKTRONIX 525 TELEVISION WAVE FORM MONITOR OSCILLOSCOPE. Used to monitor video wave forms165.00

BIRD IM-89/UR SWR INDICATOR, 200-400 MHz, 0-50 Watts 1 to 6 swr UHF version of the model 43 . . . . . 65.00

FR-4/U FREQUENCY METER, replaced by Military BC-221, range 100 kHz thru 20 MHz, has built-in scope and audio oscillator heterodyne unit that generates 100 mV output at 50 Ohms .001 accuracy, with calibration book 65.00

TS-230E RADAR TEST SET, measures power and frequency range 8500-9700 MHz 39.50

TS-505/U VTVM, 0-250 Vac, 0-100 Vdc, 0-100 M resistance, ac frequency response 30 Hz to 500 MHz, high input impedance, portable ruggedized construction, complete with probe 45.00

HP-185B OSCILLOSCOPE with 187B dual trace amplifier, dc to 1000 MHz 10 mV – 200 mV/cm, timebase 10 NSEL-10 PSEC +X2, X5, X10, X20, X50, X100 magnifier, sweep rate 40 PSEC 350.00

HP-410B VTVM, ac 0-300 V, dc 0-1000 V Ohms 0.2 to 500 milliohm, freq 20 Hz to 700 MHz 85.00

TEKTRONIX 181 TIME MARK GENERATOR 95.00

HP-614A SIGNAL GENERATOR, 900-2100 MHz, metered modulation and calibrated output 195.00

MEASUREMENTS 82 SIGNAL GENERATOR, freq. range 20 Hz to 200 kHz in 4 ranges and 80 kHz to 50 MHz in 7 ranges, output 0 to 50 Volts mod 0-50%, ideal for VLF/HF work 225.00

SG-103/URM-25F SIGNAL GENERATOR, 10 kHz thru 50 MHz in 8 bands, calibrated output, crystal calibrator, modulation 400, 1000 Hz 0-80% 275.00

SOCIAL EVENTS

Because of our publication schedule, all notices of social events must be received by the 15th of the third month preceding the event's occurrence. For example, a hamfest announcement for June 27th must be received by March 15th. Unfortunately, we cannot guarantee publication of notices received after this date.

ROCK FALLS IL
MAR 7

The Sterling Rock Falls Amateur Radio Society Hamfest will be held March 7, 1976 at Sterling High School Field House (bigger and better location), 1608 - 4th Avenue, Sterling IL 61081. Tickets $1.50 advance — $2.00 at door. For info write — Don VanSant WA9PBS, 1104 - 5th Avenue, Rock Falls IL 61071. Talk-in 94 simplex.

TOLEDO OH
MAR 13

The 21st Annual Ham Auction. America's Largest. Saturday, March 13, 1976, at Lucas County Recreation Center, Toledo, Ohio. Auction, flea market, commercial displays, prizes, XYL luncheon ($2.75 by 3/1/76). 8:00 am to 5:00 pm. $1.50 advance (SASE), $2.00 after March 1st. Talk-in 146.52. Toledo Mobile Radio Association, Box 273, Toledo, Ohio 43696.

BERRIEN SPRINGS MI
MAR 13

The Blossomland Amateur Radio Association's 10th annual hamfest will be held Saturday, March 13th, at the Berrien County Youth Fairgrounds, Berrien Springs. Advance registration $1.50; $2 at the gate. For info, write: BARA, PO Box 345, St. Joseph, Michigan 49085.

BELTSVILLE MD
MAR 14

The annual Maryland FM Association's Electronic Swapfest will be held on March 14, 1976 from 0830 to 1530 hours at High Point High School, 3600 Powder Mill Road, Beltsville, Maryland. Donations are $2.00 per person, and tables will be available for $3.00 per table. For advance tickets and/or reserved table send appropriate remittance to David McCrory WA3TKW/KQI2199, P.O. Box 111, College Park, Maryland 20740. Please make checks payable to the Maryland FM Association, Inc. Prize drawing will be held at 1500 hours. Talk-in will be on 146.16/146.76 MHz. Any correspondence with reference to the Swapfest should be directed to: David McCrory WA3TKW/KQI-2199, Chairman Electronic Swapfest, P.O. Box 111, College Park, Maryland 20740.

VERO BEACH FL
MAR 20-21

The Bi-Centennial Treasure Coast Hamfest will be held at the Vero Beach Community Center Saturday and Sunday, March 20 and 21, 1976. Sponsored by Vero Beach Amateur Radio Club, Inc., and St. Lucie Repeater Association, P.O. Box 3088, Vero Beach FL 32960.

EAST RUTHERFORD NJ
MAR 20

The Knight Raiders VHF Club's auction and flea market will be held on Saturday, March 20th, at St. Joseph's Church of East Rutherford, Hoboken Street, East Rutherford, New Jersey. Free admission, free parking, refreshments available. Talk-in on 146.52 and 146.94. Doors open at 11 am. Flea market tables: $5 for full table, $3 for a half table. Reserve your tables in advance by writing to The Knight Raiders VHF Club, Inc., K2DEL, P.O. Box 1054, Passaic, New Jersey 07055.

WASHINGTON DC
MAR 24

1976 ARRL Technical Symposium on Mobile Communications will be held on the evening of Wednesday, March 24, 1976 at the Statler Hilton Hotel, Washington, DC. Areas of interest are: HF/VHF/UHF mobile communications, repeater technology and operations, signaling and control techniques, special mobile communications (AMSAT, ATV, RTTY, etc.); especially subjects of interest to both amateur and commercial mobile radio users. Summaries are due by February 1, 1976. Manuscripts, photo of author and biographical sketch of amateur/electronic background due by March 1, 1976. Write: Paul Rinaldo K4YKB, 1524 Springvale Ave., McLean VA 22101 or call (703) 356-8918 evenings.

TOWSON MD
APR 4

The Greater Baltimore Hamboree will be held April 4, 1976 at 8 am at the Calvert Hall College, Goucher Blvd. and LaSalle Road, Towson MD 21204. (One mile south of exit 28, Beltway-Interstate 695). Food service, prizes, contests and a giant flea market. 250 tables inside gym. Registration $2. Over 1000 attended last year. Information: Contact Brother Gerald Malseed at school address or call 301-825-4266.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

HAPPINESS IS A NEW RIG

One of the greatest joys of hamming is getting on the air with something new . . . a rig, an antenna, a new mode. Unfortunately, one of the more frustrating aspects of hamming is trying to find out what to buy.

At the heart of the problem is the fact that there are too few amateurs to present a market for ham gear which attracts larger and better organized companies — thus most of the ham gear manufacturers are small outfits, often run as much as a hobby as a profit-making business. It is no fault of the entrepreneurs who run these companies that they can't afford high-powered advertising agencies to write and produce their ads . . . marketing and research consultants to determine the sales potential of products and to see that they are made and delivered on a schedule . . . professional writers to prepare spec sheets and ad brochures . . . etc.

Few men have had the experience it takes to be familiar with all of the aspects of managing a manufacturing firm . . . they may be good engineers . . . or good salesmen (has there ever been one person good at both?) . . . or they may know marketing . . . yet, when they start their own company, suddenly they are expected to be experts in all of these fields, each of which takes years to learn. They also have to know accounting, production, corporate financing and management, stocks and bonds, how to let contracts, printing, packaging, shipping, etc. Just the business of getting familiar with shipping routines is a job in itself, with hundreds of trucking firms to sort out, a weird assortment of mail rates, UPS rates, etc.

Is it any wonder that many of the ads for ham gear are written more from the viewpoint of the manufacturer than from the prospective buyer . . . you? Is it any wonder that getting information about a new product is sometimes an almost impossible exercise? The ads say little; you send for info and either get nothing or else perhaps a copy of the ad. Here you are waving your money and the manufacturer seems to be doing everything he can to push you off.

Add to that the problem of getting delivery. Maybe you decide that you really must have a certain rig. You try to find a dealer ad for it and there isn't any. Or perhaps you do find one, call the dealer, and find that he thinks he will get a unit for you in six weeks (six months is not unusual on some gear).

A POSSIBLE CURE

One thing that might help this whole situation would be some feedback to the dealers and manufacturers of how you, the customer, feel about what is happening. In practice, we've been doing quite a bit of this already, but without any serious organized effort behind it. Many readers, when they get frustrated enough, write to us and plead for help. In many cases we have been able to break things loose.

It seems to me that this should be expanded. I think that the industry would react well to better feedback from customers. I may be biting off more than I can chew (I do that every now and then), but I'd like to enlist your cooperation in an experimental feedback test.

First, there are the ads. If you are unable to find an ad for something you want to know about, drop me a line . . . mark the letter "Feedback" so I will give it priority. It is awfully frustrating to want to know about something and have to look through a year of back issues to try and get data on it. Manufacturers should advertise up to date listings of gear and prices so they are easily available.

If the ads do not tell you what you want to know, write Feedback. Ads should be written from your viewpoint, not the manufacturer's . . . they should explain what the benefits are to you in using the gear, what it costs, and where to get it.

If you send for Reader's Service (and I've been meaning to speak to you about that . . . you have *not* been sending in your reader's service coupons and I know who you are, you slacker) and info is slow in coming or insufficient, write Feedback. That holds for RS for any hamrag, by the way, not just *73*.

If you have trouble with any dealer, write Feedback. Please be sure that you are being absolutely honest with me . . . if you are screwing around with a dealer and are trying to pull a fast one, don't bring me into the hassle. Be sure you are honest about this and have not been fooling yourself because you pulled a stupid stunt and don't want to admit it. I pull 'em too and it is painful to face up to such things. The motto on my wall is comforting . . . "Intelligence is No Impediment to Stupidity."

If you get spec sheets or brochures which leave you cold, write Feedback. If you get hung up with a rig or kit which is a rip-off, write Feedback.

As far as I know, *73* is the *only* ham magazine which puts its loss of money where its editorials are . . . *73* refuses to run ads for firms which appear to be ripping off the readers . . . or causing them severe headaches . . . or seem to be ripping *73* off. It only amounts to a few lost pages of ads a month . . . perhaps a loss of about $5000 a month in ad revenue, about the cost of a 32 page section of the magazine. Would you rather have another 32 pages of magazine and have to worry about being ripped off by an advertiser?

Send your comments to:

FEEDBACK
73 Magazine
Peterborough NH 03458.

One other thing . . . please don't write and ask which firms are not permitted to advertise in *73* . . . our lawyers insist there is no way to pass along this information without opening ourselves to possible legal harassment. Sorry about that.

CHARLIE THE BOOTLEGGER

The anarchy on the CB bands promoted by the FCC's giving up on any serious effort to contain the action there seems to be spreading . . . to the ham bands. Not that we haven't been sort of expecting this.

The use of Yaesu ham rigs for CB sideband is proving a serious temptation for some of the more adventurous CBers. When they run out of steam on the 23 CB channels they start tuning the 10m and 15m bands and hear a lot of silence. What the hell, the FCC doesn't do anything to them on 11m when they ham, run high power and work skip, so they fire up on 15m and give it a try.

One group tried this in an outskirt of New York recently and got stomped by local hams who got the FCC into the act and squashed the CB expansion effort. We need a lot more hams, but that isn't the way to go about it. This was in Far Rockaway.

I'd like to hear from ham groups who are having problems with CB expansion . . . and what they have done about it. I have a feeling that it is time for the home building crew to get busy and come up with some good direction finding gear so we can form posses and find these chaps quickly. It may be that a visit from a half dozen or so hams will convince them to go back to the old 23. If it doesn't, the

FCC will need as much help as it can get in the way of names, addresses, recordings, etc.

Oh, before I forget . . . it is legal to make recordings of CBers on the CB bands if they are breaking the law. The secrecy rules state specifically that they do not hold if any law is being broken . . . and when was the last time you heard a CBer not breaking the law . . . at least by not using his call? There are no restrictions to making tapes of ham band activities . . . the secrecy rules exempt ham transmissions.

WHEN DOES MY SUBSCRIPTION EXPIRE?

Those two numbers under your call letters on your subscription label are the key . . . the first indicates the month and the second the year of your last copy . . . 56 would expire with the May 1976 issue. Now you know as much as we do.

A FIRST?

I claim the first bicentennial QSL delivery for 1976 . . . any arguments? The contacts were made at 0620 EST (no record, of course) and the *73* bicentennial QSL cards were delivered in person to AA1KPS and AC1PVF at 0727 EST January 1, 1976. The contacts were made on two meters from Peterborough NH to the stations in Somerville and Concord, Mass. The cards were delivered in Concord NH. Chuck, Sandy and I were on a field trip to check out some HTs under working conditions. Chuck, who runs Tufts Radio (New England's largest ham distributor), makes it a point to know how good the gear is that he is selling . . . and I have to know how good the equipment is so I know whether or not to accept ads from the manufacturers. Truly dedicated people such as us willingly give up our New Year's Day holiday to work hard under rigorous conditions for your benefit . . and to get in a little skiing.

SAROC — AN EXPENSE ACCOUNT VACATION

After skipping the SAROC hamfest for several years I made the trip down again to see what, if anything, had changed. Not much had. FM has taken a back seat to microprocessors in the exhibits, but that was to be expected since this is the wave of the future for amateur radio.

Exhibitors were enjoying the pleasures of Vegas during the evenings and griping about the scant turnout of hams during the days. January is definitely the off season in Vegas and, other than amateurs and an embalmers' convention or something, not much was doing and the big acts were out somewhere else. Buddy Hackett (one of my favorites) was up in Aspen skiing.

The Smothers Brothers were there. I've been one of their fans for many years . . . starting with their record albums, way before they got into TV. They were great, as usual. I understand that Dick is an amateur, by the way.

Other than the few manufacturers' exhibits, little seemed to be doing with the hamfest. The biggest attractions were the microcomputers . . . one by Hal using the Motorola 6800 chip had a first rate game of 21 set up . . . most appropriate for Vegas. It afforded an opportunity to gamble without losing money . . . and that is indeed unique in that city. Not that I should gripe about the gambling . . . this time I won.

That's right! And at the game giving the worst odds in town . . . Keno. Along about my third $1 game I came up with four out of four numbers and an amazed cashier paid out $114. I was so flabbergasted that I put some dimes in a slot machine and made a bingo there too for $10 more. I changed it all into bicentennial silver dollars and had the whole works stolen a couple days later out of my hotel room. Easy come, easy go.

The MITS systems were on display, being pushed by The Computer Store of Los Angeles. This was my first look at the MITS Altair 680 (using the 6800 chip) . . . surprisingly small package. I got my first look at the Jolt computer. It uses the Fairchild F8 chip and was an impressive unit. I'd have pictures of all this for you, except I didn't lock my cameras up in my hotel room and they got swiped along with the bicentennial silver dollars. From now on it's a metal suitcase with a good combination lock and a bicycle locking chain to go around something in the hotel room which can't be removed. If they want my suitcase they'll have to take along the sink.

SAROC is a nice expense account vacation for the ham industry.

ITU PREPARATIONS

Past amateur preparations for International Telecommunications Union conferences have been less than minimal, despite $100,000 being set aside for just that use. We went into the last big frequency conference in 1959 with virtually no planning and with no requests for more amateur bands which could then be used as bargaining chips. Through an incredible lucky fluke, U.S. amateurs did not lose out that time.

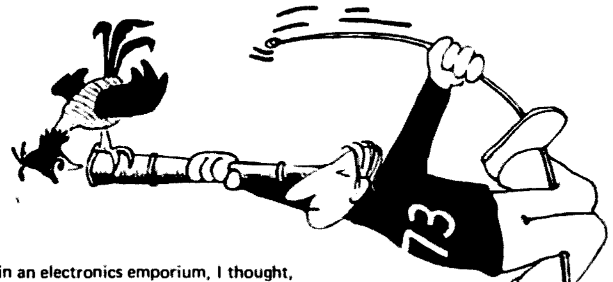
The more recent satellite ITU conference had almost as much planning and the end result was that amateurs suffered a catastrophic loss . . . 99.99% of the UHF frequencies were lost, with only a tiny segment on 450 MHz remaining. All the great ideas for worldwide amateur microwave systems via satellites went down the tubes . . . all because there was no planning, even though the money was there to pay for it.

Happily, things look brighter this time. The next ITU conference is scheduled for 1979 and an amateur committee has come up with some requests for expanded and additional ham bands. If this looks extravagant, remember that at one time amateurs had 7000-8000 kHz and 14,000 to 15,000 kHz, too. And how about that ULF band!

The frequencies suggested in the first draft of the amateur WARC-79 allocations table are as follows (from the West Coast DX Bulletin*):*

160-200 kHz	*420-450 MHz*
1715-2000 kHz	*902-928 MHz*
3500-4000 kHz	*1215-1300 MHz*
7000-7500 kHz	*2300-2450 MHz*
10100-10600 kHz	*3300-3500 MHz*
14000-14500 kHz	*5640-5925 MHz*
18100-18600 kHz	*10000-10500 MHz*
21000-21500 kHz	*24-24.25 GHz*
24000-24500 kHz	*48-50 GHz*
28000-29700 kHz	*71-76 GHz*
50-54 MHz	*165-170 GHz*
144-148 MHz	*240-250 GHz*
220-225 MHz	*300 GHz and up*

Looking West



Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

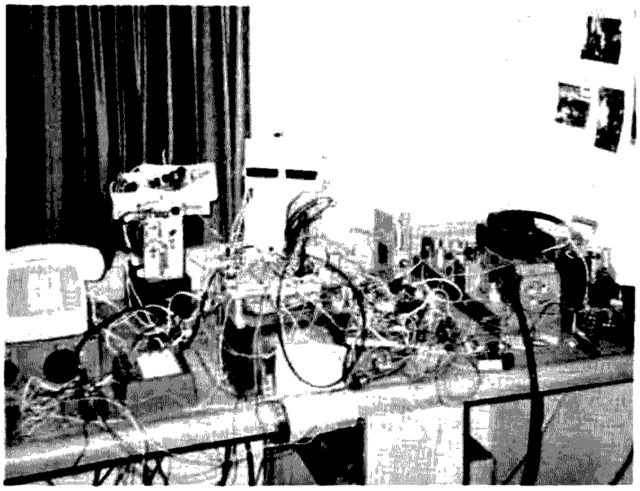
Now that was one #$&% of a football game they played out here today. Possibly one of the biggest upsets in football history. If you are one of the few that missed it, I am talking about the Rose Bowl game played here in Pasadena but a few hours ago. Ohio may have gone in as the favorite, and that first half it seemed like our local UCLA team had forgotten how to play football, but somewhere "the gods" were smiling on us and what took place in that second half. Well, I guess it's one for the record books! You can't imagine in your wildest dreams the joy that abounds in LA tonight. "Our boys done did it, so celebrate!"

We have spent a lot of column space the past few months on the topic of amateur radio public relations — getting the word out to the general public. I had intended to devote this month to but one topic: VHF-FM in the sunny southland, and in fact most of this column will be just that. However (oops, there's that word again), I came across a book in my travels around the San Fernando Valley that bears mention.

Actually, it was just after mailing last month's column to Peterborough during my lunch hour. Having wolfed down one of Grassi's fantastic Italian sausage sandwiches and a Coke, I still had about 25 minutes before I was due to be back at work. I decided to stop by Sandy's Electronics in Canoga Park to see if any new and interesting goodies were to be found. I was browsing through their bookcase when my eye was caught by a rather interesting title, *The Super 8 Handbook.* Rather an odd volume to find in an electronics emporium, I thought, as I gave it the "once-over" . . . looks interesting . . . hmmmmm . . . five bucks . . . hmmmmm . . . why not?

Little did I know the goldmine of information that I acquired when I paid my $5 to the cashier and went merrily on my way back to "ye olde saltmine." It was during my afternoon break that I began to get a glimmer of what I had in my hot little hand. First, it reads like I try to write — simple and to the point. You do not have to be a pro in the motion picture industry to grasp what the authors are trying to say. It starts by explaining in simple terms what Super 8 MM photography is and how it differs from other motion picture formats. It takes you step by step through every phase of Super 8 photography, and when the need arises, it stops to explain itself.

Want to know how to set up proper artificial lighting? See page 79 under filming techniques. Want to learn how to edit your film so that no splices are ever seen? Start on page 155 and keep going. There is even a construction project or two such as an inexpensive home brew camera dolly. I cannot begin to tell you the wealth of information cleanly and clearly packed into those 240 pages by the authors



First, a visit to the site of the ultra-sophisticated Sylmar autopatch repeater WR6AJP.

George D. Glenn and Charles B. Schloz. They are award-winning Super 8 filmmakers and tell a lot about how they did it in this volume published by Howard W. Sams & Co., stock #21001. If what I have written in the past about this motion picture format interests you, then I suggest you get a copy of *The Super 8 Handbook* even before you hit the local photo shop to look at equipment. If you do, you will know a lot about what you are looking for before you enter the door. For what it's worth, I hereby give *The Super 8 Handbook* ten gold stars and the "official" (?) Looking West recommendation. Now on to FM . . .

Let's wind up the coverage of the Ventura Convention and the SCRA meeting held there. As to the convention itself, I would be a poor person to judge, as I arrived late and never got a chance to visit the exhibits or partake of the seminars. In the gripe department, I have only one, and it has to do with the banquet. I am not one who believes that at an affair such as this one should have to stand in line, cafeteria style, to get one's dinner. To me, "dinner" or "banquet" suggests service to your table and all the trimmings that go with it. Again, this is purely personal, and the only negative I came upon that evening. On the positive, the food was good and the people sponsoring the convention came up with a special after-dinner treat that more than made up for the food line.

Now I ask you, how many conventions have you been to where you ate good food, listened while a keynote speaker like Roy Neal K6DUE held your mind captivated, and ended the evening with Alvino Ray and his orchestra? That was the bill of fare presented for those attending Ventura '75. I definitely enjoyed it; I think you would have, too. As I write this, close in my mind is SAROC '75 to which I will soon travel. Well . . . that report is next month!

Meanwhile, back at the SCRA meeting . . . quite a bit of time was spent discussing the problem of uncoordinated repeaters, but no concrete solutions to the problem were derived. The problem is that voluntary frequency coordination is just that — voluntary. It's a handshake among amateurs, and when one or two amateurs don't want to partake of that communal handshake, what can you really do? Keep offering that "hand" is one thing that most everyone attending agreed on. Keep trying to develop lines of communication with the owner of such a system, and do your best to make him "see the light." In one such conflict, it looks as if this approach is meeting with success. When they realize it is to the mutual benefit of all parties, amateurs really can learn the art of communication. Communication is the first step toward negotiation, and negotiation is therefore the first step toward solution.

Personally, I tend to prefer having any differences within our "community" settled from within. It is now a historical fact, one well proven by past experience, that when you are forced to go to the Commission for assistance, most of the time this assistance comes in the form of rather stringent regulation. After having fought hard for a good number of years to eliminate all or at least most of the effects of 18803, we do not want to make any move now that would turn the clock back for us.

It is still my belief that the simplest solution lies in some form of official recognition by the Commission of the work being done by regional frequency coordinating organizations. Note that I say coordinating organizations, not individual coordinators. I feel very strongly that a coordinating organization, whether it is called committee or council, should be made up of representatives from not only the ranks of repeater owners, but also from regional organizations representing all interests (repeater FM, simplex FM, remote base operation, AM and SSB use, and other more exotic modes). The concept of the individual entity (amateur) acting as an area coordinator is one that I personally do not agree with. Not that there have not been some truly outstanding people taking on this burden and doing an exemplary job, but is it fair to all? Is it possible for any individual to be totally objective in a situation where possibly one of his or her best friends is involved? Remember, coordinators like all of us are human beings — people — and no person that I know could be termed as perfect. I know that I am not, and I doubt if I could remain totally objective in every case or in every dispute that would come my way if I were a frequency coordinator. It is for this very reason that I doubt if the Commission would be inclined to "officially recognize" any one individual amateur in a given area as "supreme voice" on such matters.

On the other hand, a coordinating organization, one made up of all interested inhabitants of a given segment of spectrum, is a horse of a different color. By the very fact that no two people think exactly alike on all matters, you have built-in controls and are forced to develop organizational guidelines directed to benefitting the vast majority. Giving each repeater owner an equal voice in all matters affecting VHF-FM repeater operation has proven its true viability. I suspect that this simple precept has been the key of success for the SCRA and other similar organizations. Now, with the recent introduction of a number of multi-mode all band coverage radios for two meters (and unless I miss my guess, similar equipment in the future for 50 MHz, 220 MHz and 450 MHz), it will soon be incumbent upon anyone involved in frequency coordination to take steps to insure the sanctity of users of these other modes, for as more and more of such radios proliferate among our numbers, this will become a necessity. If organizations that are now involved in repeater frequency coordination take the initiative and solicit the most knowledgeable users of these other modes into their organizations, it may well prevent chaos from developing in the future. It will also show the Commission that repeater/FM enthusiasts are not isolationists. It will show that we are interested in the welfare of all spectrum users, and may be the kind of key necessary to obtain that sign of official recognition that is now so necessary.

If this sounds a bit different than the recent ideas set forth by the ARRL, I must at least credit them for putting "the bug" into my head about where the future might lead. While the basic ideas are sound, from the foregoing you probably guess I do strongly disagree with the concept of a Regional ARRL Appointed Coordinator. No matter how strong the controls from Newington, it would be too easy for a monarchy to develop should the wrong person wind up entrusted with the future of a given area. Rather, I would like to see the League solicit the formation of coordinating councils in areas now served by a single amateur acting as coordinator, and simultaneously recognize existing councils as the official representatives of those areas in which such councils exist.

Step two might be the formation of four area-wide organizations (i.e., East Coast, Mid-West, Mountain and West Coast) that would be made up of representatives of the smaller regional organizations. This would serve two purposes. First, it would let "neighbors" get to know one another and at the same time provide a platform where problems common to all in that area could be worked on. On this level, lines of communication could be developed between the four regional organizations and an ongoing exchange of information vital to standardized national growth could be maintained, and then disseminated to the local organizations. Meetings of such area-wide organizations could be held in conjunction with a major

Next, a late night interview with WR6AJP's licensee, Jim Hendershot WA6VQP.

amateur convention within that geographic area, or better yet, by use of longer range communication on 75 SSB or whatever you please. Actually, regular on-the-air meetings would accomplish a lot more than one or two meetings eyeball each year, but these are just suggestions, and admittedly open for improvement. Anyhow, going one step further, that being to a national and possibly international level, I can foresee the top echelon being a modification of the now existing VHF Repeater Advisory Committee, i.e., a reorganization to a VHF Spectrum Utilization Advisory Committee. Rather than being appointed by ARRL HQ, this "top drawer" group would be composed of four or five "elected" members of each area-wide organization and would be assigned the task of dealing with *all* VHF/UHF problems that required handling on a national basis. In addition, since VHF operation is not isolated to the USA, I could see an open invitation being given to foreign representatives of VHF/UHF interest to sit in and exchange ideas with us. Similar to the way that the ARRL Board of Directors meet, this committee could hold similar meetings either quarterly, semi-annually or annually as necessity would dictate. Travel costs for such national meetings could be generated through shared funding on the part of each local organization or that in combination with partial funding from the delegates themselves.

Note the difference: From the "grass roots" local level on up, no one individual is appointed. On every level, those in positions of power are elected by their peers. There is no one individual anyplace with supreme power over anyone. Rather all decisions on each level are handled by majority vote resulting in, basically, a democratic republic for the VHF-oriented amateur — one with the possibility of developing worldwide ties. In this bicentennial year, not a bad goal to shoot for. As a "long-standing" League member of some two months now, I offer these suggestions to both them and you for consideration, in the hope that they may be of some true utility.

LOOKING WEST VISITS AN OPEN AUTOPATCH AND VICE VERSA

Ever been visited by a repeater? Believe it or not it has happened more than once around this QTH and I have the pictures to prove it. OK . . . to be honest only once did a complete repeater, along with the person that created it, pass by to spend an evening, that being about three months ago when Mark WA6DPB stopped over to show me a new creation for 420. Got some good color slides of that one and perhaps we can get a "cover" out of one of them in the future. Maybe . . . huh, Wayne?

Anyhow, it was a visit by Jim Hendershot WA6VQP, earlier this evening that has lead to the following. Jim, better known around here as "Jr," passed by to show me the new receiver that will soon serve as the "ears" of his two meter open autopatch repeater system WR6AJP — 146.865 in — 146.265 out. Jim's system Is located here in the San Fernando Valley in an area known as Sylmar, basically the northeast corner of the Valley. AJP is one of the Inverted California Plan split-split systems that has proven that what was thought up out here really does work — an open autopatch on an inverted split-split that operates 24 hours a day without any adjacent channel problems. WR6AJP is one of two fully open autopatch systems serving the Los Angeles metropolitan area, the other being WR6ADH on 147.72 in — 147.12 out. There is a third autopatch system, WR6AKB in Palos Verdes (146.745/145), that also purports to be an open autopatch; however, its owner requires regular users of the autopatch facility to become "club members" and provide ongoing support for the "club." To my way of thinking, this latter stipulation takes WR6AKB out of the truly open autopatch category even though the repeater system itself is open access carrier squelch. By contrast, both ADH and AJP operate under the premise that voluntary user contribution must support their continued operations. While I have never spoken with Wayne Curley WA6NRB, owner of ADH, on this matter, the following from the June 16, 1975 SWAPS NEWSLETTER is a very sensible approach in my opinion.

"What is my fair share of the phone bill? The amount of the donation in support of the phone bill is based on how much a user uses it. Each minute the phone is in use is 6¢, whether he calls Whittier or Hewhall. Of course, there is the cost of the basic phone service, plus the coupler, etc., which is part of the phone bill also. With a totally open autopatch system, support is strictly voluntary. So just remember the more calls, the more time, the more money."

Note the phrase "strictly voluntary." Simply, if you are one of those stalwart souls that is providing your area with open autopatch service, technically, you are doing so "out of the goodness of your heart," and user support of your operating expenses is something really up to the whim of your users. However, when one decides that he will become a regular user of an open autopatch system, he takes on a very important moral obligation to show some form of support. No open autopatch can long survive unless those amateurs making use of its facilities give ongoing financial support. I personally look at any autopatch system as a friend doing me a favor by supplying me with an extension telephone in my car. If it were an extension of my own phone and I used it, I would have to pay the costs involved. Now if a friend were to put an extension of his phone in my home, and I were to make use of said phone, I would be morally obligated to pay my share of the bill. The guy providing you with an open autopatch is doing just that — giving you an extension telephone that you can make use of while mobile and the aforementioned moral obligation does indeed exist. The responsibility for defraying costs rests on the shoulders of all that partake. I would much prefer to see open autopatch repeaters prosper on the basis of voluntary user contribution rather than the road that WR6AKB has gone, since when an autopatch system is forced to form a "club type operation" to insure survival, and even if such a club is open to membership by any interested amateur as is the case with AKB, can it truly be said that such an autopatch repeater is an open autopatch? If the very concept of the open autopatch, a la the ADH and AJP type operation, is to survive this initial time period, it is up to those that make use of these systems, up to you.

I might be sticking my neck out a bit, but the aforementioned SWAPS NETWORK June '75 NEWSLETTER has a lot of good information about operating on an open autopatch repeater with some very good basic common sense ideas on this topic. Perhaps a note to them at PO Box "B," San Gabriel CA 91778 will bring you a copy if any are still available. If not, I will try and find space in future columns to print more of the SWAPS NETWORK's ideas on open autopatch repeater operation.

The story of WR6AJP itself is an interesting repeater story and it will be part of next month's Looking West, along with what took place at SAROC, and if space permits, a few other goodies. In the meantime, I hope that the pictures entice you enough to be back next month for the complete WR6AJP story. No, that photo of the machine itself is not a put-on. What is pictured is a fully operational two meter open autopatch that has never "been down" due to equipment failure! Who said the art of home brew is dead?

EARLY AERONAUTICS BRANCH, U.S. DEPARTMENT OF COMMERCE

In the early part of its organizational phase, the Aeronautics Branch of the Department of Commerce was very short of help. Applications for pilot, aircraft and mechanics licenses were pouring into the Washington office. They had the country divided into regions with a Supervising Inspector in charge of each. About all the Washington office was able to do with these hundreds of applications was separate them according to regions, then ship them out to the Supervising Inspector of each region. Since the District of Columbia was in my region, I would stop in at headquarters as often as necessary and pick up my new applications, sort them out and make up itineraries.

The pay on this job was something like $300 a month to start. You were provided with a book of government travel requests to take care of transportation. When you were away from your official headquarters you could collect $6 per diem to cover food and lodging, tips (not over 25¢), taxies, street cars, buses and local phone calls (not over 10¢) on an expense account. Don't you wish you had a shot at a deal like that?

My earlier trips were made by train and bus. One I remember quite well took Frank Jerdone and me to various places in North Carolina. We started at Raleigh and split up to cover two itineraries. Mine took me to Winston-Salem, Greensboro, North Wilksboro, Maxton, Hamlet and back to Raleigh. I arrived at North Wilksboro a little before noon. I had one applicant there for aircraft and pilot licenses whom I tried to reach by phone. No phone. So I went to the local police station, identified myself and asked if they could help me locate the fellow. They "hemmed and hawed" and said they would see what they could do. I told them I would be having lunch at the restaurant down the street and would appreciate any information they could get me. Well, while I was having lunch, a fellow came in and sat down at my table. He asked me why I wanted to get in touch with the applicant. I told him and showed him my ID card. "Oh," he said, "You're from the government up in Washington?" I said I was. Then he said "Well, the feller you wanted to see won't be available. There's a bus leaving for Winston-Salem in an hour and my advice to you is to be on that bus." I didn't argue with him. *I was on that bus.* The remainder of that trip took us to Rocky Mount and Norfolk Naval Air Station, where they gave us a lift over to Langley Field. After a weekend at Langley renewing old acquaintances and three working days at Richmond, we returned to home plate in Washington.

Since quite a few pilots at NAS Norfolk and Langley Field had expressed a desire to obtain a civilian pilot license, I got approval to spend a few days there checking pilots for transport pilot tickets. The Department assigned me a brand new J5 Laird for the trip. Now the Laird was a beautiful shiny ship, *but* it was an open cockpit job with no heater; the month was December and no winter flying clothes went with the machine. I had my own helmet and goggles so I bundled up as best I could in my business overcoat and set sail for Langley. The temperature on the ground at Bolling was about 45° so I flew low to Langley and didn't suffer too much. The trip back to Bolling a few days later was a different story. It was around 30° on the ground at Langley the morning of my departure for Bolling (Washington). As the trip progressed, I got colder, and the colder I got the more I leaned on the throttle, so I made the 130 mile trip in about an hour. That was unquestionably the coldest ride I ever had. They had to help me out of the ship at Bolling.

First thing I did upon my arrival at the "Deep de Com" hangar was to ask the man in charge to "scrounge" some winter flying gear for me. He said he thought he could help and this is how he did it. It seems that only a few days before, there had been a fairly extensive fire in one of the Bolling Field hangars. Now this is an event that every Supply Sergeant on the field welcomed, because it enabled him to claim that almost every item in his charge that had been lost, strayed or stolen was destroyed in that hangar fire. So all my man had to do was to get a winter flying suit, boots and gloves from a Supply Sergeant who would survey them as having been lost in the fire. I got my winter flying gear for a $10 bill. Since this was some 48 years ago, I guess that the statute of limitations will cover all participants.

As of March 1, 1928, my official headquarters were changed from Washington to Philadelphia. They also issued me a J5 Travelair. I was glad to swap the Laird for the Travelair. The Laird was a much better looking plane and it was faster, but the Travelair was much better for getting in and out of small fields — particularly the many where you had to land up hill and take off down hill.

After four months of operating out of Washington as a temporary headquarters, I was pleased to get the permanent assignment to Philadelphia. First thing I did was to rent a small apartment and move Wayne and my wife, Cleo, to Philadelphia.

The Ludington Philadelphia Flying Service operated the municipal flying field just south of the city. Bob Hewitt, an old friend, was the manager. They did a lot of flying instruction, passenger hopping, cross country work and had an excellent service and repair shop. Bob was kind enough to provide me with a small room for a field office, complete with a desk, chairs, etc. Everyone was happy.

Next month more about the rest of my time with the "Deep de Com" at Philadelphia and a first class hunting trip.

LOOTED: Heath HW-202, series 01324. Setup for 34/94, 31/91, 22/82, 16/76, 28/88, 38/98. Stolen January 1, 1976. Also taken: a first aid kit for volunteer rescue squad. Info to Blacksburg Police Dept. Blacksburg VA 24060, telephone (703) 552-2311. Douglas Hall WA4UNS/P4

ROBBED: Drake TR-22C, S/N 850265. Taken in San Diego. Reward offered. David M. Anderson WA6KHH/6, PO Box 1097, Lemoore CA 93245.

Chalk It Up As A Lesson

"Hey honkie, whatcha doin' down here?" is not an uncommon phrase heard in the neighborhood where Mike (WB6ZHD) and I found ourselves. We were there to supposedly "help" a newcomer on WR6ACS get his new rig more on frequency. Since he had given his call as KL8436B or some such, it isn't too difficult to figure out why we placed ourselves in this neighborhood late one afternoon. We had a San Francisco policeman with us.

This story has an unfortunate ending for some unlucky ham somewhere that has had his IC-230 ripped off. Of course, the metalized sticker containing the serial number was merely peeled off. Why doesn't some ham club start a project to encourage manufacturers to *engrave* serial numbers on the chassis or some other hard-to-replace part? But more important, why don't all hams engrave their driver's license and the two letters signifying their state on every easily saleable item in their home???? According to several police departments, the driver's license is much easier to trace than your callsign. It takes approximately 15 seconds to trace any driver's license if you indicate the state. It might take weeks to trace an owner by his call letters. Quite often the well-known callbook is outdated by the time it gets into print, and, believe it or not, a lot of policemen never heard of the callbook.

I personally removed both covers of this IC-230 looking for some kind of ID. There was none. The policeman called in a description of the rig — they had nothing on it. Of course not!!! If it is originally stolen by a "professional" thief, he certainly transports it out of the area before he sells it. So there was nothing we or the police could do in this episode except congratulate the owner on making a good buy (at $150.00) and advising him of the illegality of operating without an amateur license.

You don't have to conceal your engraving; in fact, it is better if it is very obvious — on the cover, front panel, or chrome frame — the thief then has more difficulty in disposing of it. It *DOES NOT* make the rig less valuable if you decide to sell or trade it. Just give the purchaser a "bill of sale" or a note. Then, if it is stolen later, the police would of course contact you, and you would be able to steer them on to the next owner. Even if it has gone legally through several owners, if each passed on a bill of sale with it, it could still be traced to the final owner easily, and believe me, the police would do this bird-dogging gladly when they suspect they have a thief. It may be their best evidence.

Think about it — the price of an engraving tool is a hell of a lot less than insurance, and quite often more apt to get your equipment back. Don't overlook engraving your TV, your tape recorder, your sewing machine, typewriter, etc.

The lucky new owner of that IC-230 is a legitimate CBer, and thought he was buying a CB rig. Now I do *NOT* want to hear descriptions of all of the stolen IC-230s across the country. Just chalk it up as a lesson to engrave your driver's license and state on your next one.

Dick Altman WA6AXV
San Francisco CA

Let's Grow Up

Reprinted from The Canadian Amateur.

Are we mature enough to run our own show or do we always have to be told what to do?

For many years now, in fact far longer than most of us can remember, the lower amateur bands have by regulation (law) been subdivided into "CW" and "phone" segments. Initially this was done to provide "guard" bands to protect services on adjacent frequencies from phone sidebands and splatter. But now the bands have been officially divided up between CW and phone mainly because of the inability of amateurs themselves to sort out and amicably resolve their own problems.

Why is it that in Canada (and the U.S.) it is necessary to have *laws* that tell us what we can and cannot do within our allocated frequency bands? Amateurs in other countries seem to be able to carry on successfully without the need for such official intervention. Surely our amateur fraternity has now reached the age of self-determination and no longer needs to be *told* what or what not to do. Why should the DOC have to expend many man-years of work (and thousands of dollars) in an attempt to solve an unresolvable problem? They never will be able to satisfy everyone. We can do the job just as well (or maybe better) ourselves.

It is my firm belief that CW and phone sub-allocations (except for band-edge guard bands where necessary) should not be made part of official legislation. If we are not mature enough to sort this problem out among ourselves perhaps we should not be enjoying the hobby. If we carry on in our present regimented fashion, CW may soon be prohibited in certain segments of the bands, and there will be sub-bands for SSB, USB, LSB, RTTY, television, etc.

So what if there is some interference between CW and phone operations — is it all that terrible? It may even improve our operating techniques and capabilities.

Such an "open" band concept does not in any way affect the incentive concept since phone and other privileges would still be allocated according to the qualifications (class of radio operator's certificates) and experience of the licensee.

Legislatively this can be easily accomplished by simplifying the list of amateur frequency bands in the (Canadian DOC) General Radio Regulation, Part II, to show only the complete amateur bands and by deleting Schedules II through V. When an operator becomes appropriately qualified, he would be authorized to operate phone on any one or more of the applicable high frequency bands without reference to any specific segment of the bands.

These are strictly the opinions of the writer, who has listened to the pros and cons of this so often vociferously argued subject for these many years, as well as having been involved, from the official side, in trying to find an acceptable solution to the multitudinous "demands" of groups and individuals within the fraternity.

Let's grow up and do the job ourselves as responsible and reasonable individuals.

LETTERS

THE MAILMAN DIDN'T RECOGNIZE IT

What kind of a nut are you? I mean really you *must* be one to be against one of the best changes in format that you could possibly have made! I can now see the damn printing for a change!

This January issue is really great and I cannot fathom your having such a hang-up on going to the larger size. More room for bigger and better schematics, layouts, pictures and above all easier to read. Best move you could have made!

This issue has a lot in it, too. I am going to build the automatic dialer or something similar to it. I really enjoyed that article. Of the other many fine articles, one worthy of special mention, at least for me, is the one on "Module Kits – a Low Cost Homebrewing Breakthrough." I was interested in this article because it is what I have been engaged in for several months, but I am not as far along as G.R. and Bob. I haven't gotten to the packaging stage, yet, just the kits.

I just wanted to write and encourage you in the new magazine format. There are always some nuts who are against "everything" new, but I'll wager a donut that the great majority of your readers will be enthusiastic about the larger size!

Lon Allbright W6SLF
San Diego CA

Nice work! Your new format for *73* is F.B. Really like it.

F. Tuttle W8QLL
Midland MI

Got my giant issue today and those advantages you wanted are showing up. The mailman, who delivers my mail next door (he can't read), didn't recognize it: It arrived in perfect condition, for once. I don't know how long he'll be fooled! I found that it swats flies better than last year's model, does better no-nos on the kiddies, and makes great placemats.

Don't be too upset over the size; XYL says that quality not size is important (that's what she tells me). Some will like it; some will learn to like it.

Richard Fosburgh WN5PWE
Dayton TX

I received my January 76 issue of *73* and was pleasantly surprised at how easy the new size of type is to read. Please count me as one in favor of the new size, even though it will require new bookshelves for the shack.

Peter K. Von Hagen WA6HXM
Palos Verdes Pen CA

I just received my January issue of *73* and want to congratulate you and your staff on an outstanding job in making the transition to the enlarged format. With a background in journalism, I can appreciate some of the problems you must have had in making layout changes.

I had every expectation that *73* would continue to be a quality periodical, and it appears that I haven't been disappointed.

Dan Davis K3DSQ/4
Langley AFB VA

I like it! I like it! I like it! The new size. The articles. The projects! I even sent for QSLs and a new callbook from this issue.

Good before . . . greater now. Keep on . . . keeping on!

Don Dye KØJVE
University Park IA

I didn't think you could do it, but you did. You actually topped the November 1972 issue with the January 1976 issue. This has got to be the greatest issue of any amateur magazine in history.

There is no way of telling what the reaction will be to the new format, but for what it's worth, I like it. For one thing, the drawings seem to be quite a bit larger, and the older I get the more I appreciate things like that.

For another, the magazine seems to lie flat and open easier. This is reminiscent of the saddle binding you used years ago when you first started *73*.

I must admit I was a bit upset when the Nov/Dec 1975 issue arrived, but I understand the problem now, and this fantastic January issue more than makes up for it.

Bill Gulledge K5UAR
Downsville LA

Just got the January 76 issue. New format looks great!!

Glenn R. Kurzenknabe K3SWZ
New Cumberland PA

Your January 1976 issue is the best ever in the 13 years I have been a subscriber.

Harry Roblyer WØDLM
Burwell NE

I love the new format. Only one comment: Move the printing over toward the edge of the page. It would make it easier to read with one hand folded over. What ever happened to GRRREEEN? About time it came back I think.

Ron Veelik WA6LTH
Crestline CA

TREATED

I have recently treated myself to a 3 year subscription to your magazine after "sampling" it from the local newsstands for some months. *73* is a magazine in a class by itself. It is really great to be able to get hold of such a varied collection of "matter" every month. Your magazine has truly got something for everyone and really doesn't waste the volumes of paper that certain other ham radio publications do on useless chitchat. I especially appreciated the various articles on weather satellite receiving station construction by WB8DQT. I am now planning the construction of my own station using some of his circuitry and some of my own. I would like to suggest that WB8DQT consider publishing a book on the topic in the same way he worked on the SSTV handbook.

John L. Webster VP2DN
St. Augustine
Trinidad, W.I.

WB8DQT's new Weather Satellite Handbook *should be on the 73 presses right now. – Ed.*

SMELL NICE, TOO

Maybe all of the people who've built the SD Sales Clock Kit wonder, as did I, about what the devil you can house the clock in really fast and easy. Here's my idea, and it costs just about nothing.

Have someone give you either after shave lotion or all-purpose(?) lotion put out by English Leather in the eight ounce size. The cardboard box (which used to be real wood) is perfect for the SD circuit boards. The front cutout needed is almost exactly ½ by 2½ inches, and the whole job can be done with an X-Acto knife. No LED mask is needed: Just let the six displays poke right through the hole you've cut in the side of the box. If you cut the box right, you won't even have to fasten down the circuit boards; they'll fit nicely with friction between them and the cardboard.

I know that the clock case people will hate this idea, but why spend money when you can have a nifty case and smell nice, too?

Tom Donohoe W2NJS/WA1PXV

GETTING OUT WHAT YOU PUT IN

Just had to pass along some "observations" regarding "Getting Out" in the January issue.

I firmly believe that Mr. Lichtgarn is a "quitter."

I was just around the 40 year old mark when I became interested in ham radio and, of course, it's hard to "teach an old dog new tricks." My line of work is about as remote from electronics as auto racing and ice hockey, so had to enter an entirely new and rather frightening world.

With the aid of a friend, VE1AMZ Clive Bagley, I was able to pass not only the "Experimental" but also the "Advanced" ticket. For those not familiar with Canadian rules, the code is 10 wpm for the "Experimental" and 15 wpm for the "Advanced." I can truthfully say that it was not easy for me and took a great deal of time and effort on my part. Now that it's over and behind me, I can sympathize with others having a rough time, but not quitting. I think the old adage of "you will only get out of something exactly what you put into it" would apply in this case.

I often remark to others that if my XYL, VE1BEV, can pass the exam, anyone can.

Hope I made my point clear without making it sound like I'm blowing my own horn.

Thanks, Wayne, and I like the new format!!

Ralph F. Campbell VE1QU
Dartmouth N.S.

I agree with your answer to Fred Lichtgarn. Anyone that doesn't have the patience to learn the code doesn't belong on a ham band. About your magazine – I'm glad it's around. It's what originally got me interested in amateur radio, and has kept me interested and working on my Novice license. I've already passed the code; the theory comes in 3 weeks. I hope to move to General in 6-8 months after getting on the air. Again, thanks *73*, for being around!

FAR AND AWAY THE BEST

Thought you might be interested in hearing the results of my letter about XU4XA that appeared in the Nov/Dec issue of *73*.

First off, I received several nice letters, but wonder of wonders, W8JTW (now WA2BRI) sent me a Xerox copy of one of my XU4XA cards and an original! He had two — I worked him when he was in Columbus, Ohio in 1939.

Then later, W3HTG, now W6HTG, and current chief operator at KPH, paid me a personal visit, and *he* brought me another XU4XA card, as he had two! He was in Atlantic City, N.J. when we were QSO.

W3LTH wrote and says old W8CRA, now W3CRA, is still hale and hearty and going strong in Pennsylvania. Also had a note from Ed Hopper W2GT — he is still quite active.

Now — if I could get a Xerox copy — or better yet — an original of my old XU8LR and XU8XA cards when I was operating in Shanghai, I'd really be pleased!

I still think *73* is far and away the best magazine published in the ham field, Wayne — I like the new and bigger size also.

Keep up the fine work, and I assure you I'll continue as a subscriber as long as I'm around.

Al Lower W6CLB

BURNED OUT

I have a cathode ray oscilloscope model 670, made by Hickok, and the power transformer has burned out. I would like to be put in touch with someone to wind the power transformer for me, as I cannot obtain one from Hickok. I have the engineering drawing from Hickok with the power windings listed. I would appreciate it if you can help me.

TWO HANDS NOW

The magazine in the new format arrived and the setup looks quite attractive. The only complaint I have would be that it now takes two hands instead of one to hold it up so if one wants to scratch his ear while perusing the periodical, he has to lose his place.

Regarding 2 meter cooperation and band plans and all, in some cases the high officials making the decisions are also high officials in repeaters and there has been some criticism that one will feather his own nest rather than make objective decisions for the benefit of the general public. I note one of the "private repeater" people is on the ARRL Committee.

Paul Schuett WA6CPP/WA7PEI
Wallace CA

WATCH OUT SOUTHERNERS!

I wanted to comment on the Looking West column that Bill Pasternak writes for your thick magazine. I don't know if Bill is a new guy or an old timer in Southern California, but the problems the 2 meter repeater councils in the North and South are having goes way back before repeaters. In fact, it has nothing to do with Ham Radio at all but is purely geographical in nature.

Here is the true problem — it seems that there is a Northern California and a Southern California. And for years the two factions have been fighting over almost everything from politics to tax dollars and water rights. For instance, it appears that when a Governor is elected he usually gets most of his votes by whether he resides in Southern or Northern California — not by whether he is a Democrat or a Republican.

So Bill, don't take it so hard. We Northern Californians have been trying to secede from Southern California for many years. We have all this beautiful country, forests, water, blue skies (smog-free), fairly unpolluted beaches, water, the Golden Gate Bridge, fewer people, water and freeways that actually move at rush hour. And Southern California — well as far as we've been able to determine up here, their biggest assets are smog, people, deserts, and Ronald Reagan the actor.

The Northerners had hoped that the earthquake they had in the South would do the inevitable — make Southern California break off and float out to sea. But since that idea didn't work, tell ya what we're agonna do. Let's go ahead and make it two states like we planned to anyway. Then you guys down there can take Jerry Brown and we'll elect a Northerner for Governor. Or we'll keep Jerry Brown and you folks can elect a new Governor. I heard on the wireless the other day that Richard Nixon is a citizen of your new state. Perhaps him!

Now, you ask, how will we make out financially when Southern California is so rich? That's easy — we sell water to the South and become rich like the sheiks in the Mideast with their oil wells. Watch out Southerners! It gets awful dry down there.

Bill, we can hear you shaking in your boots down there but please don't worry — it sounds great to us. And what of the future of Northern California? Well — today a new state — tomorrow a new country. That way we can ask for foreign aid from the rich Americans. We could also have our own version of the FCC — terrific!

As for working out the problems with repeaters — perhaps you'd like to make an appointment with our ambassador. He will be glad to send you several crates of red tape and forms in 32 parts to fill out. The North shall rise again — but don't worry Bill!!!

RELIABLE SOURCE

Just a note to let *73*'s readers know how pleased I am with one of your advertisers. Dealing with Communications Specialists, manufacturers of the ME-3 miniature PL encoder, has been nothing less than a pleasure. Their products are excellent and delivery is usually less than five days cross-country.

Reliable sources are hard to find. Thanks.

Charles B. Anzman WB2PVH/WR2AIL
Freeport NY

SHOT DOWN AGAIN

In the interest of fair play and downright revenge, I am writing and documenting the below information concerning unethical business practices on the part of one of your former advertisers in the hopes that others will be spared the frustration, mental anguish and expense I have gone through.

On 14 March 1975, I placed an order with Trigger Electronics of River Forest, Illinois for a Drake low pass rf filter. Being a patient person, I waited expectedly until July for my filter. When it did not arrive as expected, I wrote Trigger Electronics and requested to know the disposition of my order and an immediate refund if the merchandise had not already been shipped.

In reply, Trigger stated that the product had been out of stock and that I could expect shipment within two weeks. No mention was made of my desire for a refund, and in fact this was the first indication that my order had even been received in the first place.

When the filter had not arrived by September, some two months after the purported shipment date, I again wrote and demanded an immediate rebate of my purchase price and in turn was advised that I would have to provide additional information so that they might locate the "paper work." I had already provided them with copies of all previous correspondence which remained in my possession.

When I again wrote in October and threatened legal action, I was advised that I could expect them to carry out my wishes once they had completed researching their files. I have heard nothing since then.

I brought this matter to the attention of other local hams in this area via the 2 meter repeater and was appalled at what I heard. Numerous hams in this area have been the recipients of equally poor service by Trigger Electronics, service which is unethical, non-existent, and in my estimation, outright mail fraud. All, other than myself, have resigned themselves to the fact that they have been taken and forfeited their hard earned green, some losing money in the three figure range.

This type of operation must not be allowed to continue and I am sincerely seeking your attention in exposing this shoddy operation to amateurs nationwide via *73 Magazine*.

Raymond E. Ault WA6EVX/KG6
FPO San Francisco CA

ELEVEN METER FREAK?

In response to the recent letter submitted by Scott Liebling WA3OXG of Pittsburg PA, thank you Scott for your letter regarding CBers.

Yes, we are people just like you are! I resent being called an 11 meter freak and the constant nit-picking in the ham magazines concerning "people" who use CB.

I will even give you "hams" the pleasure of seeing in black and white these words from a CBer:

"In my opinion, as many as 85% of the people who key their over modulated D104 mikes belong in juvenile homes."

There once was a time when I too was engaged in chitchat, arguing with the channel "landlord" that I too had a right to use "his" channel, etc.

The time does come, though, after countless letters, calls, etc., to the FCC, that one realizes that it's useless to even bother.

I feel, Scott, that many people now might go the way of the "ham" if they were not to be embarrassed for ever being a CBer.

I recall listening in one evening on a 2 meter FM when a new "ham" was really getting a going over as he was once a CBer. He was being called his former "handle" of "Yogi Bear," etc.

I am no longer active in CB although I still have all my equipment and intend to use it again some day, if things ever straighten out on the CB band.

What I would like to say, though, is something about the good CBers I've known and become involved with.

I've personally seen and been part of thousands of CBers who searched for 8 days under the most horrifying conditions for a lost child, assisted police and fire depts. on Halloween, walking and bike marathons. I've seen CBers donate hundreds of quarts of blood, collect thousands of dollars for a truck driver who was badly hurt, hold benefit coffee breaks for burned out families, dying children, etc.

Assist the Coast Guard with missing boats when people were foolish enough to go too far and depend on a

CB radio, report accidents, render first aid on the scene — and I could go on and on.

Believe me when I say we would love to weed out the bad apples, but there are also some very fine people. Please don't forget them, for they might want to become one of you, if you'll let them.

I'd also like to mention in this letter the Newport County Radio Club to which my son belongs. Bob is now WN1VWN thanks to the fine "hams" who patiently encouraged my son and held his interest by letting him become part of their activities while learning.

A special thanks to Fred Evans W1JFF, for all he's done for Bob, things too numerous to mention.

June Vlasaty KHV-1421
Newport RI

MORE ON ETCHING

I just finished reading the article by John Harrington, "You Can Make Photo PC Boards" (Feb 76). I found it to be a good article. Having also done some work with PC boards, I thought I might offer some of my own findings to supplement the article. When working with the photo sensitizing spray, I found it advisable to do it in a well-ventilated room. Wear one of those sterile masks that painters use to cover their mouths and noses. You can find them in just about any paint or hardware store.

Another type of etchant that I found very nice and neat to use is ammonium persulphate. Sold by Kepro (EPI-G), it comes in a crystalline powder form and is mixed with water when ready to be used. The advantage of this stuff over ferric chloride is that it's clear and not as messy to handle. You can see the progress of the board as it is being etched. It's also fast when heated to the recommended temperature.

If you use the G. C. Electronics sensitizing spray, don't use the Kepro developer. Some thing holds true if you buy the Kepro pre-sensitized board and try to develop it in the G. C. Developer. One way nothing will happen and the other way . . . well . . . it's back to the drawing board or should I say exposure board. In any case, don't mix brands in these two stages. There is no problem which I encountered in the etching stage. Use whatever brand you want.

One more thing: Above all, remember — whatever stuff you use, always read the warnings and the instructions and never lose respect for the chemicals you are using.

Isaac Michalowski WN2ALK
Brooklyn NY

When etching printed circuit boards with ferric chloride, it helps to warm the solution. This will reduce the etching time from about one hour to 15 minutes for small boards. Some use a heat lamp or oven, but these methods generate a lot of heat. If you use a plastic container and don't watch, it could be possible to melt the plastic.

If you have a microwave oven, that works fine. Thirty seconds or less is all that is necessary. No unnecessary heat is generated with this method. I use a glass jar with a plastic lid for small boards. Bigger boards could be done in an open tray.

A note of caution. The ferric chloride fumes might do bad things to the microwave oven so try to use a container that has some type of cover.

Max Holland W4MEA
Madisonville TN

SOME CHRISTMAS

I have bad news. I will be "off the air" temporarily. On Dec. 20, 1975 some PUNKS stole my *entire* communications equipment, and some TV test equipment, out of my garage. Here is the list: 1—Tempo FMH H. T. w/acces.; 1—HR-2 w/touchtone; 1—SX-100 & spkr; 1—Seneca 6&2; 1—Lafayette 6m xcvr; 1—Uticom 2m xcvr; 1—PCL nuvistor amp; 2—6&2m "CW" conv.; 1—swr meter; 1—12V. 4A. DC supply; 1—Sencore MU-150 tube checker/analyzer; 1—Sencore CRT checker/rejuvenator; 2—Tube caddies full of late type TV tubes; 3—Port. B&W TVs.

Loss is estimated at approximately S2,400. Some Christmas.

Gary IN 46408

KNOW YOUR NEIGHBORS

I recently had the pleasure of attending the first organizational meeting of the new Tri-State Repeater Council. This council, serving Metropolitan New York, New Jersey and Southern Connecticut, has been formed to finish the job that the now-defunct Northeast Repeater Association started. Under the very able direction of Dave Minott WA2EXP (Trustee WR2ACD, NY City), this group is attempting to clean up FM in New York and the surrounding areas and keep it that way. The key to achieving this goal is participation. The first meeting was attended by over one hundred local repeater trustees, an excellent representation, but many were not there. I urge all repeater groups, coordinated or not, to participate in this valiant effort by contacting Dave or one of the directors. The vibrations at the meeting were excellent and I feel that if ALL repeater groups are represented at the coming meetings, the TRC will work. Duke Harrison K2QPF has been retained as area frequency coordinator. Call him if you are planning a machine — it can only benefit you by coordinating.

On the same note, I have a very simple recommendation. If you are a repeater trustee and have other machines on "your" channel or 15 kHz next door, call the trustee of the other machines and say hello. At the Rochester ham convention, I ran into Tom Palmeiri WA2WKP who is trustee of the 175-775 repeater in White Plains NY. As trustee of WR2AIL here on Long Island (also 775) I made an immediate effort to say hello to Tom and develop a neighbor relationship. Now that both repeaters are COR, 24 hours a day, and constantly expanding coverage, Tom and I have avoided many problems by calling each other once in a while and letting each other know what's happening on the other end. In the near future we plan to link the two machines duplex via UHF and many other cooperative efforts are in the works. The moral is: Get to know your frequency neighbors — it couldn't hurt!

Keep up the good work reflecting FM activities in *73*. Love the new format.

ONLY LINK

Congratulations on doing it again!! Every time I think I have the "ultimate" in a two meter station, you publish another article which forces me to dig out the tools and commence to mess up the room, much to the chagrin of my long suffering first Sergeant.

At present, I am referring to the article by WA8LEM in the September issue on page 137, entitled "Adapting Telephone Handsets to FM Transceivers."

This is very easy to accomplish on the ITC Multi-2000 transceiver. A careful study of the tiny schematic revealed that pins 1 and 4 on the microphone plug are connected to ground. All that was necessary was to remove all connections from one of these pins (I used pin 1), and reconnect them to either the other pin or direct to ground. A single wire was then run from the external speaker jack on the rear panel to the vacant pin. I elected to use a hook-up which gave audio to the handset at all times, regardless of whether an external speaker was used or not.

I went the whole route with this modification and built a complete "remote" audio system in an old telephone case. If you know of anyone who might be interested, I will be more than happy to pass along the schematics and such on the external system. It definitely makes for more convenient operation and is quieter. The latter is an important item with me as I live in a barracks.

I would also like to correspond with other Multi-2000 owners and exchange ideas and problems. At present, I have a small (2 kHz) problem with my VXO. A frequency meter indicates that the output frequency is 2 kHz lower than the VXO knob indicates. I am also in need of another copy of the schematic to convert the 2000 to selectable sideband. The copy I had was misplaced (lost) in a big room shuffle in the barracks.

Many thanks for your help, both past and present, and keep up the good work with the magazine. It is about my only link with the fast changing hobby up here on this remote site.

DESIROUS

I am in definite desire to repair a Hallicrafters Receiver, Model S-40B, into working condition for monitoring both amateur and broadcast (HF) traffic. I have a copy of the schematic and an idea where the alteration was made by the previous owner. I am very desirous to have this unit back in condition in as short a time as possible.

I am also in the process of attempting to obtain a General Class Ticket!!

DIGITALITIS

Let's keep up the technical articles and "build it" articles in *73*.

With the new (UGH) size I expect to see PC board layouts!

I use a Mamiya 500 DTL with Litho film to copy the layout and then enlarge it onto 5x7 Litho film — does a good job with G-C photo resist spray.

I have contracted "Digitalitis" from your rags.

Mel Hart WØIBZ
St. Louis MO

WANTED: K6DGX

A lot has happened since you published my letter in the November/December issue.

On 24 December I passed the Advanced Class test, and now I'm anxiously undergoing the weeks-long wait for my ticket.

I found the *73* code tapes very helpful in preparing for the test. I'd like to pass along a hint for others — I started with the 6 wpm tape, since I already knew the code, having once had a Technician license. When I was copying the tape pretty well, I wondered how to get over the hump

SAN JOSE BICENTENNIAL AWARD

The Santa Clara County Amateur Radio Association (SCCARA) is offering a special Bicentennial Award to celebrate the bicentennial of San Jose CA. The award is earned by working a number of SCCARA members, and stations located in San Jose, Santa Clara County, or the Pacific Division for a total of 200 points. The points are based on the location of the station requesting the award. A minimum number of SCCARA members must be included. Also, *one* contact with either of the club stations W6UW or W6UU may be counted for special point value. Contacts may be made on any mode, on any band, but each station can be counted only once regardless of bands or modes used. No credit will be allowed for contacts made via repeaters, except that OSCAR contacts will be counted. An endorsement for all phone or all CW contacts will be available if requested (and log data verifies). Contacts to be counted must be made between July 1, 1976 and December 31, 1977. To request the award, send log data (call of station worked, date, time, mode and handle of operator) along with $1.00 US or 5 IRCs (latest type only!) to the Club Secretary, SCCARA, PO Box 6, San Jose CA 95103.

The following table indicates QSO point values and minimum number of SCCARA members that must be included (only one contact with W6UU or W6UW is allowed, not both!):

	W/in SC Cnty	W/in 6th Dist. (Not SC Cnty)	W/out 6th Dist.
Min # SCCARA members	10	5	2
Pts/SCCARA member QSO	5	10	25
Pts for Club Stat QSO (only 1)	10	20	50
Pts for other SC County Contacts (not SCCARA members)	1	2	2
Pts for contacts w/Pac. Div. (not SC County)	–	–	1

WHEAT CITY AWARD

This award is sponsored by the City of Brandon and the Brandon Amateur Radio Club and is offered free of charge. To receive the award, work three amateur radio stations in the City of Brandon, Manitoba, Canada if you live outside of Canada. Those living inside Canada must work five stations in the City of Brandon. All contacts must be made after January 1, 1967. Send log data only to: Mr. Doug Bowles VE4QZ, 1104 First Street, Brandon, Manitoba, Canada R7A 2Y4.

The following two awards are sponsored by the Nortown Amateur Radio Club, VE3NAR, PO Box 356, Adelaide Street Postal Station, Toronto, Ontario, Canada. A sworn affidavit certified by a President or Vice President of a legitimate Amateur Radio organization may be submitted in lieu of QSL cards.

WAVE AWARD
WORKED ALL VE AWARD

Contact two different stations on two different bands in each of the following 8 sections: Prince Edward Island or Nova Scotia or New Brunswick (VE1), Quebec (VE2), Ontario (VE3), Manitoba (VE4), Saskatchewan (VE5), Alberta (VE6), British Columbia (VE7), and Northwest Territories (VE8). All contacts must be made from an area within a radius of 150 miles of one point and after January 1, 1939. Submit the 16 OSL cards (or sworn affidavit) with $1.00 or 10 IRCs. All cards will be returned. Return postage must accompany all submissions.

WACAN AWARD
WORKED ALL CANADA AWARD

Contact two different stations on two different bands in each of the following 12 sections: Prince Edward Island (VE1), Nova Scotia (VE1), New Brunswick (VE1), Quebec (VE2), Ontario (VE3), Manitoba (VE4), Saskatchewan (VE5), Alberta (VE6), British Columbia (VE7), Yukon or Northwest Territories (VE8), Labrador (VO2), and Newfoundland (VO1). All contacts must be made from an area within a radius of 150 miles of one point and after January 1, 1939. VO contacts must be made after March 31, 1949. Submit the 24 OSL cards with $2.00 or 20 IRCs and return postage for QSLs. All cards will be returned. Cards submitted for WACAN can be automatically applied towards the WAVE award – please indicate if desired. For holders of the WAVE Award, submit the QSL cards for the remaining four sections (8 QSLs) with $1.00 or 10 IRCs and return postage.

FLORIDA QSO PARTY
1500 to 2000 GMT
Saturday, April 17
0000 to 0500 GMT
Sunday, April 18
1400 to 2400 GMT
Sunday, April 18

The 11th annual QSO Party is sponsored by Florida Skip. Phone and CW are counted as separate contests. The same station may be worked on each band for QSO points and Florida stations may work other Florida stations for QSO points only.

EXCHANGE:

RS(T) and QTH; QTH = county for Florida stations, = state, province, or country for others.

SCORING:

Florida stations count 1 point per QSO. Multiplier is sum of states (49 max), provinces (12 max), and DX countries (12 max). Maximum multiplier is 73. Florida mobiles and portables operating on emergency power and running 200 Watts or less, multiply total score by 2. Out of state stations score 2 points for each Florida portable or mobile station worked and one point for each fixed

CALENDAR

Mar 27 - 28*	Tennessee QSO Party
Mar 27 - 28*	CQ Worldwide WPX Contest – SSB
Mar 27 - 29*	BARTG Spring RTTY Contest
Apr 17 - 18	Florida QSO Party
Apr 3 - 4	Open CD Party – CW
Apr 3 - 4	SP DX Contest – CW
Apr 10 - 11	Open CD Party – Phone
Apr 10 - 11	County Hunters SSB Contest
Apr 24 - 25	PACC
Apr 24 - 25	Delta QSO Party
Apr 24 - 25	BARC Contest – Phone
May 1 - 2	Massachusetts Bicentennial QSO Party
May 1 - 2	Helvetia 22 Contest (H22)
May 8 - 10	Georgia QSO Party
May 8 - 10	Vermont QSO Party
May 8 - 9	BARC Contest – CW

Dec 11 - 12	ARRL 10 Meter Contest
Dec 31	ARRL Straight Key Night

* = described in last issue

station. Multiplier is number of different Florida counties worked (max 67). Final score is total QSO points times multiplier.

FREQUENCIES:

CW – 1807, 3570, 7070, 14070, 21070, 28070.

Phone – 1817, 3970, 7270, 14317, 21370, 28570.

ENTRIES:

A summary sheet is requested showing the scoring and other pertinent information. Also, your name and address in BLOCK LETTERS, and a signed declaration that all rules and regulations have been observed. Include a 13¢ stamp for results in a future issue of Florida Skip. Mailing deadline is April 30th but late DX entries will be accepted within reason. Send all entries to: Florida Skip Contest Committee, P.O. Box 501, Miami Springs FL 33166.

AWARDS:

Certificates will be awarded to the top single operator score in each state, province and DX country as well as each Florida county for both phone and CW. There are also 5 plaques to be awarded for: High single operator in Florida and out-of-state both phone and CW (4 plaques), and to the Florida club with the highest aggregate score.

At the discretion of the contest committee, stations may be disqualified for improper reporting, excessive dupes, errors in multiplier lists, unreadable logs, obvious cheating, etc. Anyone disqualified in this year's Florida QSO Party will be barred from the contest next year.

SP DX CONTEST – CW

Starts: 1500 GMT
Saturday, April 3
Ends: 2400 GMT
Sunday, April 4

Work as many SP stations during the contest period as possible on all bands 3.5 to 28 MHz. The three categories are: single operator, single and all band; multi-operator, all band only; and SWL. The same station may be worked on each band for QSO points but a powiat may be counted only once as a multiplier. All contacts must be on CW only.

EXCHANGE:

RST plus a 3 figure QSO number starting with 001 for foreign stations. Polish stations will send RST and their powiat letters.

SCORING:

Each QSO with an SP station counts 3 points. Final score is total QSO points times the total number of different powiats worked regardless of bands.

AWARDS:

Certificates to the top scorers in each category, in each continent and each country and call area of Australia, Canada, USA and USSR.

ENTRIES:

Use a separate log sheet for each band and include a summary sheet with all the scoring information. The usual signed declaration is also requested. Usual disqualification rules will apply. Entries should be postmarked no later than April 30th to PZK Contest Committee, P.O. Box 320, Warsaw, Poland.

SIX METER GROUND WAVE CONTEST

Starts: 0300 GMT
Sunday, April 4
Ends: 0700 GMT
Sunday, April 4

The contest is sponsored by the Society For The Preservation and Encouragement of Six Meters and Global Research. It is open to all amateurs, worldwide – on all modes: SSB, CW, FM, AM, SSTV, RTTY, and FAX. Any six meter contact is valid. Skip stations do count in the event the band is open, but they only count ½ point each no matter where the station is located.

SCORING:

For scoring purposes, there are four zones defined by the distance between your QTH and the station contacted. Zone definitions and QSO points for contacts with each zone are as follows: Zone 1, Stations within 25 miles of your QTH – 1 point/QSO; Zone 2, Stations 25 to 50 miles from your QTH – 2 points/QSO; Zone 3, Stations 50 to 75 miles from your QTH – 3 points/QSO; Zone 4, Stations over 75 miles from your QTH – 4 points/QSO.

LOGS:

Show your name, call, address, ARRL section, and input power. Mobiles and portables must show actual locations. For each station worked, show: call, ARRL section, zone (as defined above), time, and points scored. Show your total score, sign the log, and submit to: Phil Caruso K9DTB, c/o Global Research, Contest Chairman, PO Box 271, Lombard IL 60148. Logs must be postmarked by May 3, 1976 for scoring on May 31, 1976. Incomplete logs will not be eligible for awards.

AWARDS:

All entries will receive a certificate from SPESM. The first place total score in each category will receive a prize. Prize categories are as follows: Mobile – any mode or power; Portable – any mode or power; High power – 100 Watts or more; Medium power – 51 Watts to 99 Watts; Low power – 50 Watts or less.

Any questions concerning rules can be answered by K9DTB (Phil) at 312-279-4658 or through SPESM. All prizes are donated by Global Research.

NOVICE QSO PARTY

Starts: 0000 GMT
Saturday, April 10
Ends: 0600 GMT
Sunday, April 11

The fifth annual Novice QSO Party is sponsored by the International Novice Amateur Radio Assoc. Any class amateurs work only Novices and work each station only once regardless of bands. Please use "CQ NP" for contest call and use the lower 10 kHz of each Novice band. The following are considered as Novices: EL#Nx, HC#Nxx, HI#Nxx, KG4Nxx, KZ5xxN, LB#xx, OA#Nxx, OL#xxx, VU2xxx, WH6xxx, WL7xxx, WN#xxx and WP4xxx (or bicentennial equiv.).

EXCHANGE:

RST and name.

SCORING:

Novices multiply total number of QSOs by total number of different prefixes worked (K1xxx & WA1xxx are different prefixes, etc.). Non-Novices multiply total number of contacts by the number of different Novice prefixes worked (WN4, WN8, OA3N, OA2N, etc.).

ENTRIES:

To qualify for awards, mail logs no later than May 1st to: Andi Anderson WB5MYV, Route 1 Box 193, Heavener OK 74937. Include an SASE for results.

COUNTY HUNTERS SSB CONTEST

Starts: 0001 GMT
Saturday, April 10
Ends: 2400 GMT
Sunday, April 11

The fifth annual County Hunters SSB Contest is sponsored by the Mobile Amateur Radio Awards Club, Inc. (MARAC). Basically, the rules are as follows: Mobile stations may be worked each time they change

Continued on page 32

RESULTS

RESULTS OF THE 1975 DELTA QSO PARTY

Plaque winners are as follows: high score, Delta Division – W5DRW; high score outside division – KØGJD/6; high score, portable station – WB4DJU/4; high score, mobile station – WA5KQD/5. Only WA3VWJ/5, W4CHK and KØGJD/6 worked five stations in each of the four states in the Delta Division for the Delta Achievement Award. Results of a contest survey are available, for a large SASE and two first class stamps, from W5RUB. The first place station in each section is as follows:

DELTA DIV.	CALL	# QSOs	SECTIONS	POINTS
ARK	W5DRW (WA5RTG op)	324	62	20,088
LA	W5WG	299	60	17,940

Yes, You Can Build This 2m Receiver!

Chances are no one has to tell you how great it is up on "2." You may already have at least one rig on two, or wish you had one. Either you or some of your ham buddies may operate the local repeater(s) and maybe your club even has a repeater. If, however, by some strange uncanny phenomenon, you don't know how good it is on two meters, you'd better build yourself this receiver. If you're like most hams and already have a handle on two meters, build this unit and you can have a good back up receiver, monitor your calling repeater (no matter which one you're working), or spend a few extra dollars to add a transmitter for a dandy economical little FM rig.

For somewhere in the 35 dollar range you can receive two meter signals in the fraction of a microvolt range, run off a handful of batteries, the house current, or the auto battery, and know what's happening on two.

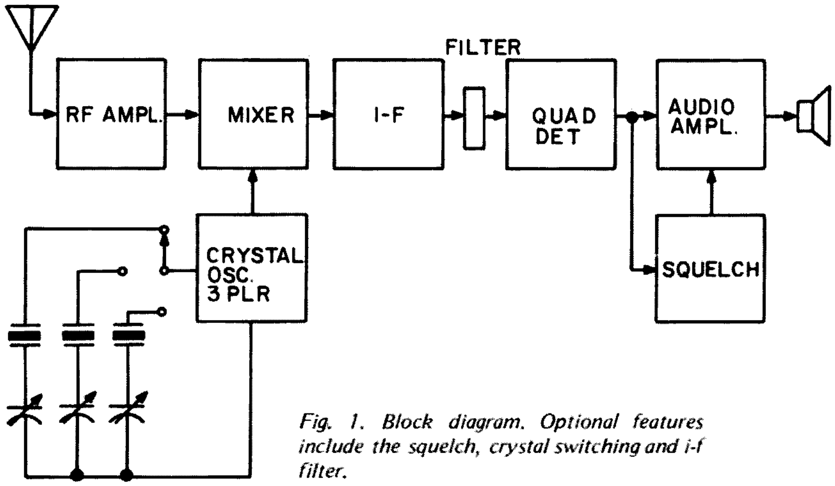

Fig. 1. Block diagram. Optional features include the squelch, crystal switching and i-f filter.

A simple, inexpensive transmitter is on the drawing board as a companion for the thing and there is plenty of room for it in the cabinet. If your junk box is full to the brim, you can probably build this unit for the cost of some of the ICs and the circuit board, etc.

The whole receiver was designed with an eye to the cost vs. performance ratio. You get the best performance possible at the lowest cost. You can leave out some of the circuits if your budget is a little strained. Sort of a "put the squelch on layaway" program. The circuit design uses the right combination of ICs and discrete circuits to give good performance and still save on the cost of the unit. Also, consideration was given to the overall circuit-by-circuit cost; that means you don't pay only a quarter for an IC (bargain, huh?) and then have to add $5.00 worth of external components to make it work. You get the best choice as far as the combination of the IC cost and external components.

Fig. 1 shows the block diagram of the receiver. The receiver is a simple, single conversion unit with no frills. As mentioned before, you can add the frills later. For instance, there is no fancy ten-pole crystal filter in the i-f, but there is enough room on the circuit board to add it for those who need it. After all, why should those of us who have only one or two repeaters in the area, on widely separated frequencies at that, pay for that added selectivity? If the action gets too hot up there later, we can add the circuit. It is a lot easier for the poor amateur to liberate ten dollars here and there than to spend 50-60 bucks a whack.

Fig. 1 shows that the incoming signals are converted to a 10.7 MHz i-f. The front end is FET and the i-f amp is an IC. The quadrature detector is also an IC. The IC audio amplifier is protected so you can disconnect it with the audio going full blast. This allows you to use a variety of speakers, headphones, etc., without worrying whether gross impedance mismatches will ruin the receiver. The squelch is treated as an option, although there are those who feel a receiver without squelch is unthinkable. It is a little noisy up there on two, so the squelch is a good one. It will operate external buzzers, relays and lights, as well as switching the audio. You can operate a buzzer with a telephone handset operation to impress the boys in the carpool, or to soothe the XYL who can't stand to hear the squelch breaking. You have a Watt or two of audio which will work fine for all but the noisiest sports cars. The entire receiver draws about 100 mA. That amount won't run your nicads down for a few hours,

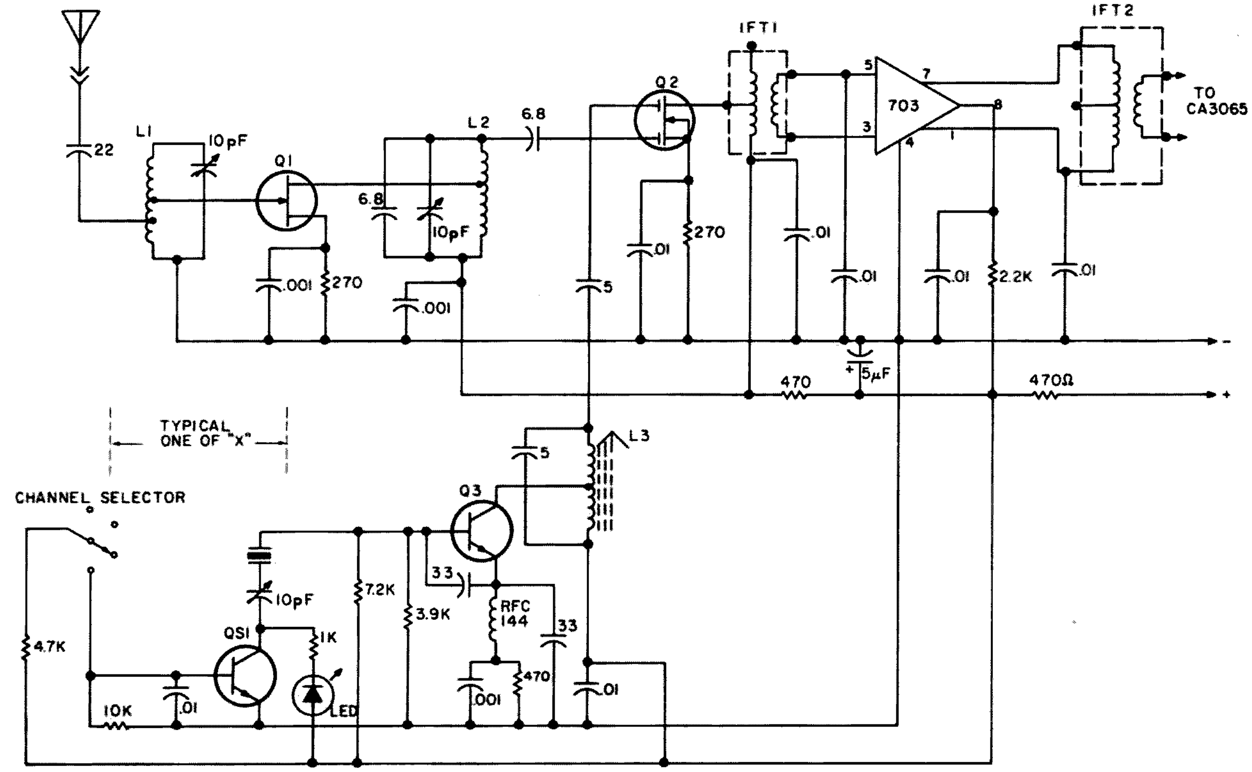

Fig. 2. Schematic diagram (continued on next page). Optional channel selector is shown. Q1: GE FET 2, F0021, MPF102, 3N128. Q2: 40673, 3N140*. Q3: 2N2222. Q1-X: 2N2222*. Fig. 2. (continued).

and you'll never notice the new addition to the electric bill.

A look at the schematic, Fig. 2, shows that the oscillator and tripler circuit are one and the same. This circuit uses crystals which triple in the same way the Regency folks do in the HR-2 (or so I'm told). That means you can order your crystals from the inexpensive units that advertise in 73 all the time offering their crystals for particular units, to that unit's specs. To find the crystal frequency, subtract 10.7 from the repeater or other desired frequency in MHz, then divide by three. For a 146.94 unit, the frequency is 136.26 and the crystal frequency is 45.42 MHz. I have had a lot of success with Jan Crystals units selling for $4.00 each; just order for the series mode.

The dual gate mixer and JFET front end provide good overload immunity and help guard against cross-modulation effects. If you find the agc-less receiver suffering from overload in your application, just add the rf gain control shown in Fig. 5.

The i-f stage uses the familiar 703 op amp. Although I have read reports of people having bad luck with the op amps, I find them extremely stable when treated right. Just keep the leads short and bypass close to the case. You won't have any trouble at all.

The limiter, detector, and audio preamp stages are part of an IC that is unique in that its original application was in the 4.5 MHz audio i-f of TVs. If that scares you, you are welcome to the popular CA3089 IC. The 3089 has built-in squelch, but the cost is nearly 4 dollars as compared to less than 75¢ for the CA3065 used here. The squelch circuit can be added for around a buck and a half or less and is far more versatile than the squelch in the CA3089. The CA3065 uses few external components in this application and will do the job well. Ignore the spec sheet that may come with the unit, unless you

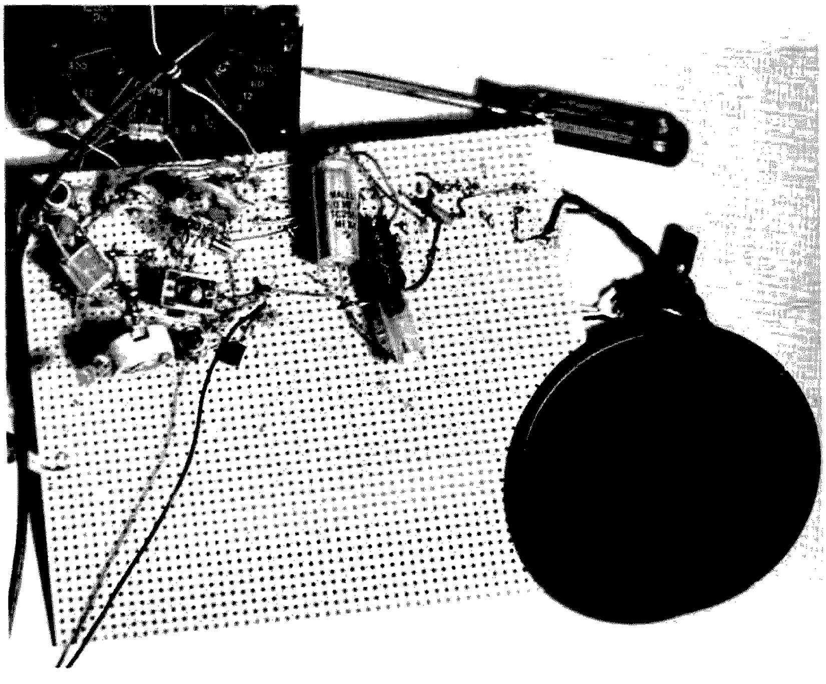

Fig. 3. This is the prototype layout. If this thing worked (and it did, very well) just about anything you can dream up should work with no problem. See the text for pointers on some pitfalls in laying out the receiver.

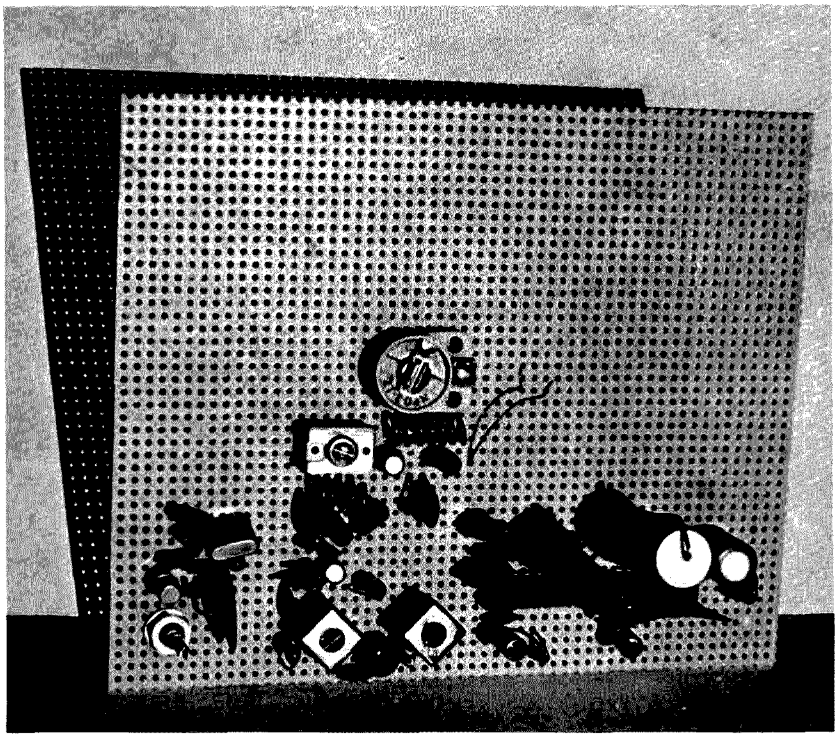

Fig. 4. This is the final layout of the breadboarded receiver circuit. Stick with this one, and you'll have room enough for add ons, and a stable receiver design.

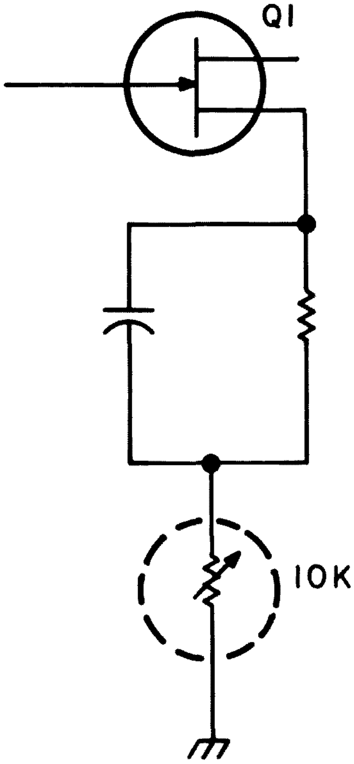

Fig. 5. Installing a 10k rf gain control in Q1 emitter when overload is a problem. When using the unit as a fixed station, it may be a trimpot "set and forget" control. Adjust for maximum gain/minimum cross modulation.

want to do a lot of experimenting. The values given work nicely.

The audio output stage uses the LM380 IC. The 380 puts out better than a Watt with a 12 volt supply and will be adequate for most applications. The best features of the IC are its very low cost ($1.60) and the few external components it requires. The gain is fixed at a maximum limit like the 703 op amp and this gives it a lot of stability as long as good layout is used.

Construction

You can use just about any layout you want. If you use my layout, you will likely have better results right away since mine is proven. You certainly should try your own if you have something in mind as the simplicity of this receiver makes it a candidate for miniaturization. If you do try another layout just try to keep inputs and outputs that are at or near the same frequency separated, shielded, or both. Note, in the PC diagram, how the ground bus is used to provide shielding between stages. The i-f system in this unit has very high gain; the CA3065 was designed to be the sole i-f amplifier in a TV system, so the addition of the 703 op amp can bring the system gain as high as 90 dB. That is pretty hard to keep stable without keeping the inputs and outputs well apart.

Just look at Fig. 3. This was the prototype circuit board while the developmental work was being done. If that worked, just about anything you dream up should suffice. Fig. 4 is a photo of the final layout. The receiver is shown as a prototype layout and there is room for the squelch circuit (layout not shown), crystal switching, even for a transmitter. You'll be reading about the add ons to this receiver later; in fact, you may even have something unique in mind for your own. If you use the same cabinet I did, there will be plenty of room for adding a power supply and the speaker mounts easily in the unit.

Substitutions

Any good ham is interested in using junk box parts in building anything, but sometimes the junk box is not full of the values the schematic calls for. For starters, you can save some money by getting the three MOSFET pack from your local Radio Shack for less than $1.50. Use two in the receiver and add one to the junk box. The gates aren't protected, but I have more static in my carpet than rf in my transmitter, and using just reasonable caution and discharging myself before handling them, I have not burned out a single gate. The 3N128 single gate makes a good front end. The 3N140 makes a dandy mixer. You can substitute paper coil forms for the ceramic forms. Better choices are the resinite forms, those brittle plastic looking things you've seen around. You probably noticed that the crystal switching circuit is strange. If you want to leave out the Q5 stages and just use the switch, just remember to use a layout like mine that puts the oscillator near the front of the case, so the switch leads will be shorter. Just ground the lug of the crystal tuning capacitor rather than connect it to the collector of Q5. The Q5 stages are not given in the PC layout.

In the i-f stages, you may steal the i-f transformers from a transistor radio (1) if it had FM and (2) if you can identify the 10.7 MHz transformers from the 455 kHz transformers in the case of an AM/FM. Use the mixer transformer from the radio as the mixer transformer in the receiver and use the radio's i-f T2 as i-f T2 in the receiver. For saving another quarter, use the bipolar transistor (if it's NPN) from the radio for the local oscillator. Be sure to use either the front end or the oscillator/mixer transistor as Q3. Oh yes, while you're cannibalizing, you may as well use the radio's volume control and/or tone control for the volume and squelch controls. Check the values to insure they are 50k or lower.

The true parts substitution nut will love this last one. Don't even use coil forms or trimmer capacitors. The heavy coil windings can be wound so that a ferrite core from a coil form (the threaded interior type) will fit inside along with a little tape or plastic sheet to insulate the thing. The slug will move in and out of the coil when you turn it since the pitch of the windings acts like threads in the coil form. You no longer need trimmer capacitors because the coil is slug-tuned. Naturally, since the inductance increases you will need to find a value for the fixed

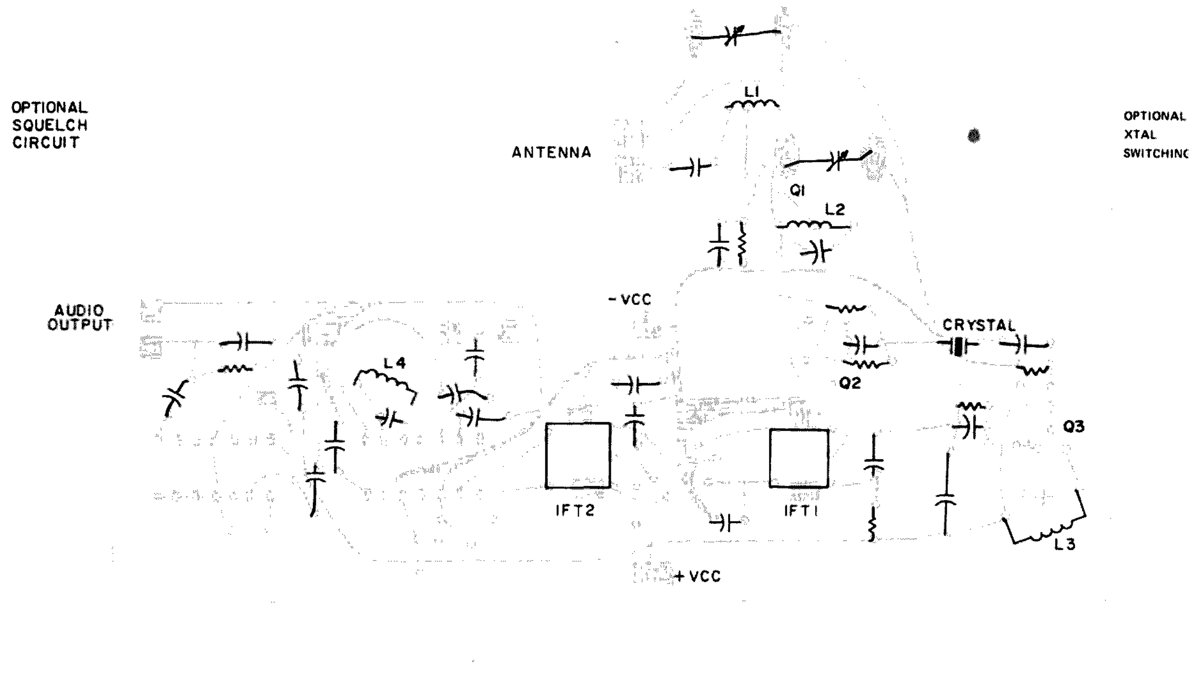

Fig. 6. Foil side PC layout. Note open areas for squelch and crystal switching, as well as crystal filter.

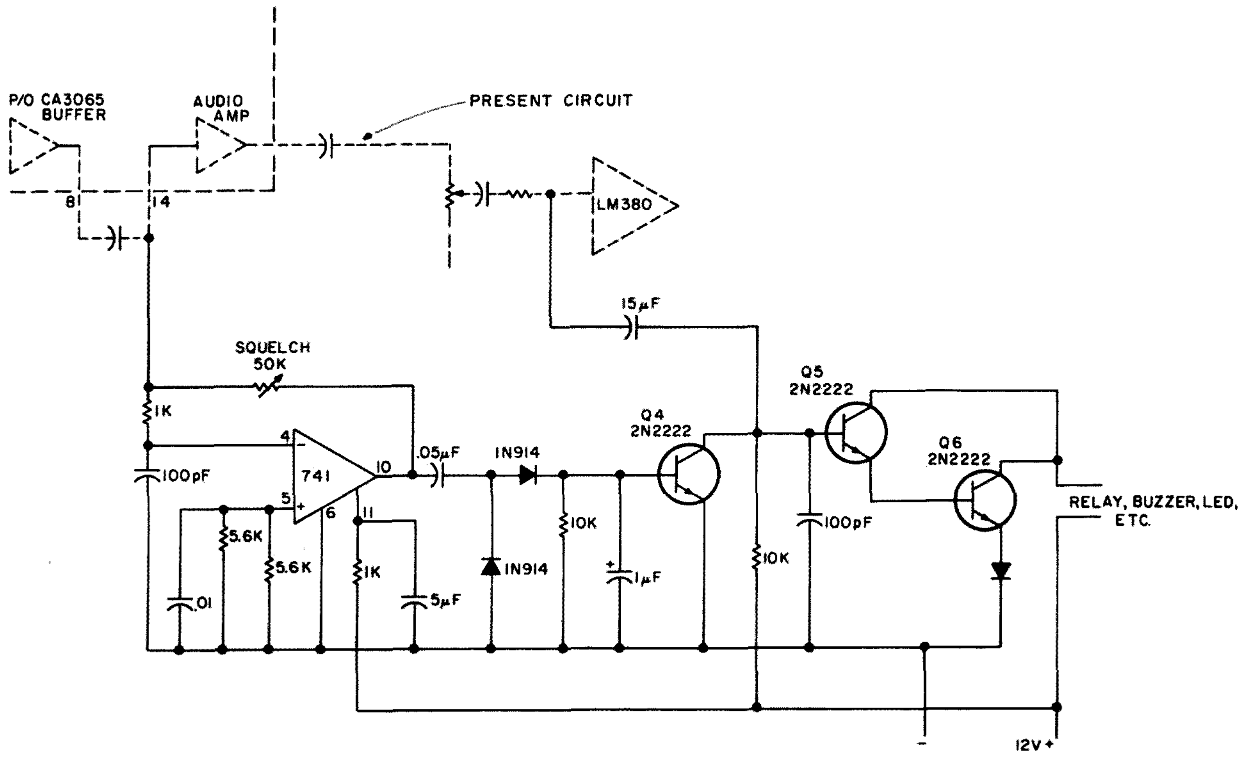

Fig. 7. Squelch circuit. Q5 and Q6 are an option to the option. They will operate a buzzer, or whatever. You will probably want to add a switch to the audible signal so it can be cut when you are in QSO.

capacitor experimentally. A grid dip meter should suffice. Don't worry too much about hurting circuit Q because the FETs don't care, and the Q in the oscillator circuit is not that critical to proper operation. You will still have to use a form for the quad detector coil since it is a relatively high-inductance unit.

Optional Circuits

While you may not consider some of the optional circuits optional, they really aren't basic to the functioning of the receiver and can be added later if you don't wish to do so now. Fig. 7 shows the squelch circuit. The optional crystal switching is part of the main schematic, Fig. 2. The crystal filter circuit is shown in Fig. 8, and the PT12194F Piezo Technology Comline filter should do the trick. You can find a slew of preamplifier circuits if you feel the need to add one to the front end. And diode protection, back to back 1N914s across the input rf amp gate, is recommended when using the receiver with a companion transmitter. This protection may not be necessary, but can't hurt since it will cost only a quarter more and might save the front end from damage from the nearby rf.

Tuneup

Accomplishing tuneup is easy. First align the i-f, then the rf stages. With an input from a signal generator or grid dipper align the quad detector for minimum noise output. Keep switching the rf on and off so you make sure you have noise without signal, no noise with; that way you don't accidentally detune the thing way off frequency thinking you're right on. Next peak the i-fs for minimum noise. Tune up the front end by giving it a signal on two meters, a gdm is fine, and again tune the front end for maximum quieting. Tweak the oscillator for maximum quieting. Then accomplish final tuneup with weak signals on the band when possible. For a sensitivity check without 2 meter signals use the gdm. You should be able to quiet the receiver from as far away from a 19 inch whip or piece of wire as you can your communications receiver. If you have a two meter FM receiver already, you can use its sensitivity as a reference. If all is well with your wiring you can stir up some action on the band.

You should enjoy this receiver. The satisfaction of knowing you built it yourself, as well as knowing how much money you saved over available commercial units should make it a fun experience. The money you save building this unit and a companion transmitter could buy the XYL a nice gift. And then maybe she'll even start encouraging this nutty hobby of yours. Of course, you can also use the left over money to buy yourself another piece of ham gear, or since you've got it sitting around, perhaps you'd consider using it to make up the difference in this week's and last week's grocery bills. ■

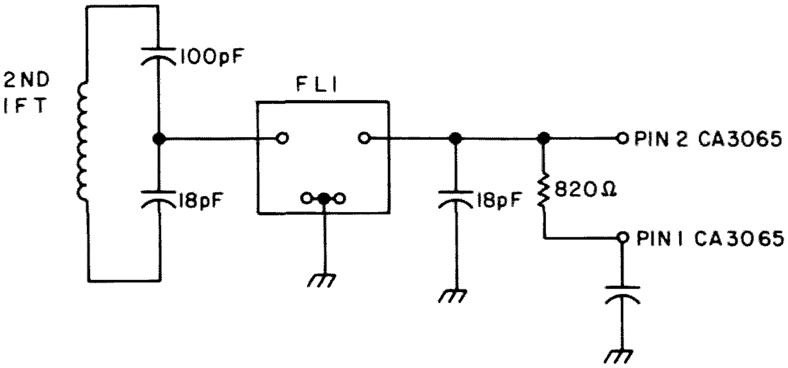

Fig. 8. Crystal filter circuit. FL1 is a PI12194F crystal filter or equivalent.

A Reprogrammable ID

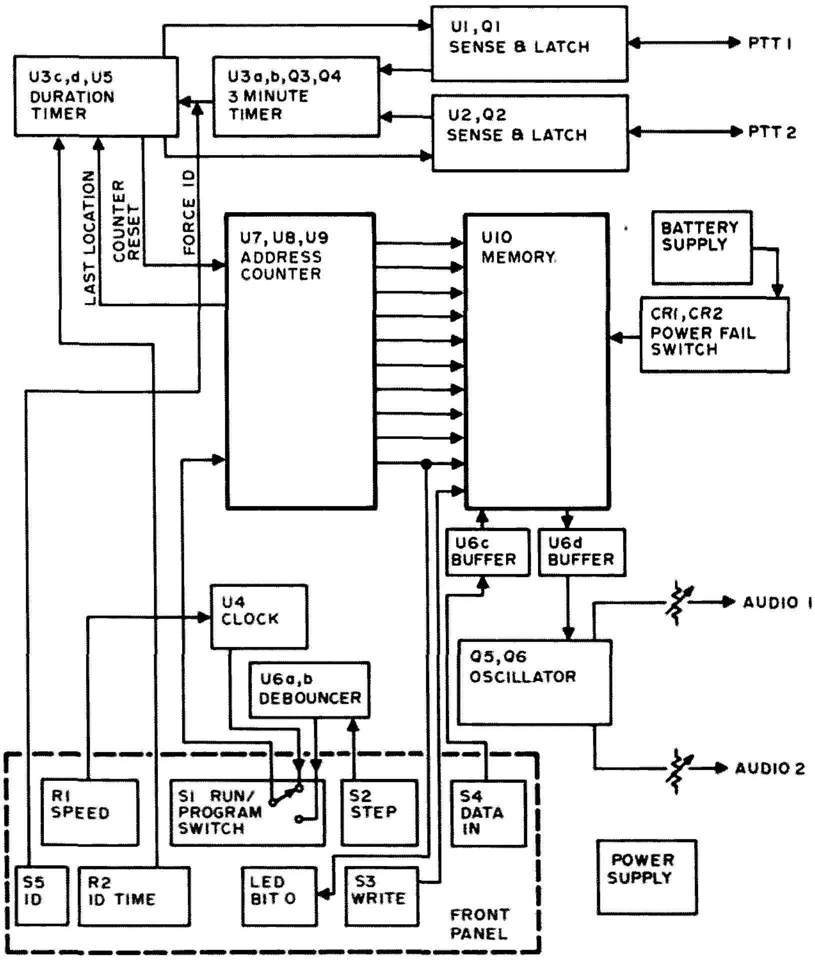

Fig. 1. Block diagram.

by
Robert Glaser WA3MSW
3922 Algiers Road
Randallstown MD 21133

There are a large number of repeaters on the air these days, and most have CW identifiers. The CW operator who takes a sojourn into the repeater bands is inundated with repeater callsigns. After a day or two on the same repeaters, listening to the dull but prevalent "DE WR3ABQ" type of repeater identification becomes rather boring. Being an avid CW operator as well as repeater user, I decided that a more interesting type of repeater identifier could easily be built. It was decided that the identifier should:

1. Be easily reprogrammable (without opening the case).
2. Have capacity for long messages.
3. Retain its memory during power failures.
4. Service two repeaters.
5. Be relatively inexpensive (under $40).

The identifier was to be used at a site where two repeaters are located with the same callsign (150 and 450) – hence the fourth point.

An identifier was designed and constructed which satisfied the above requirements. It is programmed from switches on the front panel, has a 1024 bit non-volatile memory, identifies two repeaters, and costs about $30 to $40 to build (with new parts).

Other Identifiers

The distinguishing feature of identifiers is the memory. Identifiers may be classified according to the type of memory they use. There are basically two kinds of electronic identifiers in use today. The first and older of the two uses a diode matrix for memory. The identifier is programmed by soldering diodes in a matrix. The disadvantages of this system are that large memory units become cumbersome, and that reprogramming entails opening the unit and physically moving diodes around.

The other type of identifier uses read only memory (ROM). These are fairly new devices and can store more in less space than a diode matrix. Typically, fusible link ROMs are used because these are the most inexpensive. The fusible link ROM is programmed by selectively melting fusible links inside the integrated circuit chip. Naturally once a link is melted there is no way to put it back. Generally a ROM of this type can be programmed only once. However, to change the identification in this type of identifier it is only necessary to reprogram another ROM chip and replace the old ROM with the new one.

The latter type of identifier is more easily changed than the former, but still lacks versatility in that a different chip must be purchased every time it is desired to change the identification. This would become impractical if the memory were to be changed every few weeks.

There are alternatives to the fusible link ROM. There are available programmable, erasable ROMs. These can be erased by exposure to ultraviolet light. However, a specialized and complex programmer unit is needed in order to program them. These chips are presently in the $20 price class.

There is another type of memory which, in the past, has not been used in identifier circuits. This is random access memory, or RAM. This type of memory is electrically programmable. Moreover, the 2102 static RAM has 1024 bits of storage and sells for about five dollars. There is one disadvantage to using this kind of memory — it is volatile, which means that when the power is turned off the contents of the memory are lost. Both the diode matrix and ROM are non-volatile. A power fail battery can make the RAM immune to short line power failures. The reprogrammable identifier uses such a system.

Theory of Operation

Fig. 1 is a block diagram of the identifier. The oscillator generates a sidetone with two variable level outputs for the repeaters. The memory unit keys the oscillator, and an address counter drives the memory. The identifier has two modes of operation: program and run. The run mode is normal operation, and the program mode allows the memory to be programmed. In the program

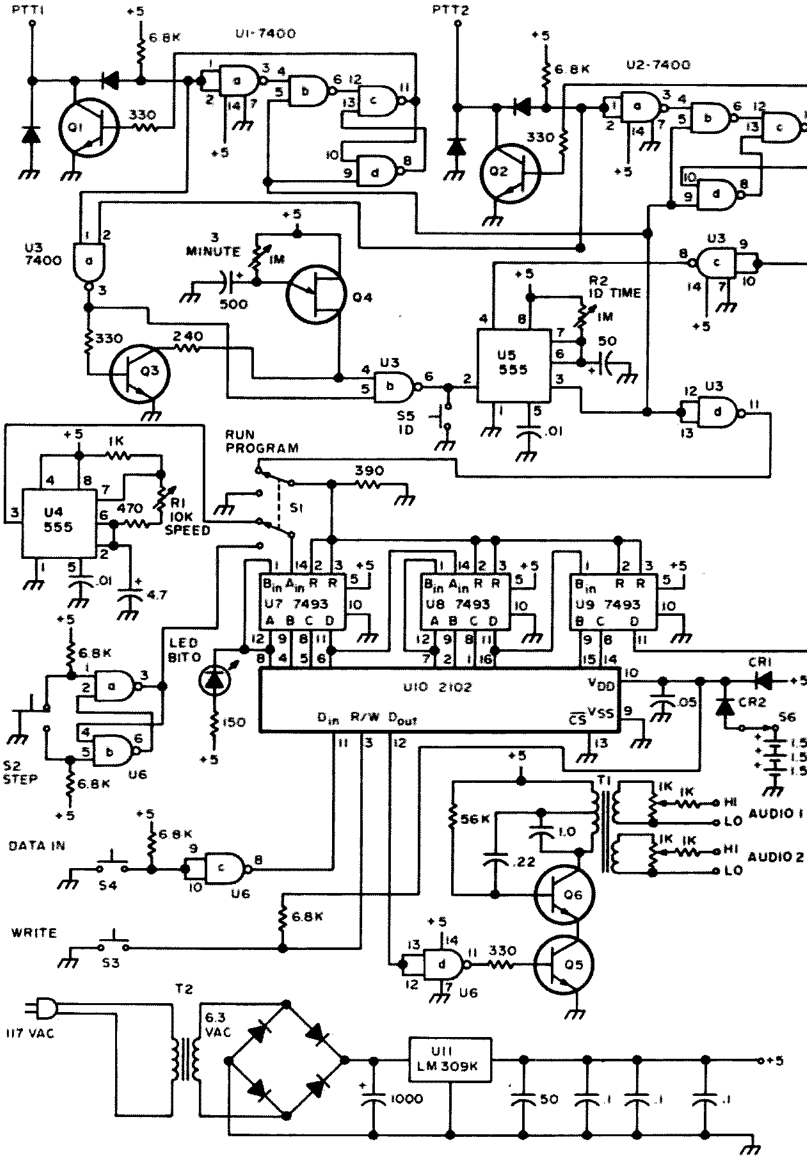

Fig. 2. Schematic.

mode, the address counter is incremented by a push-button on the front panel, and ones and zeros can be written into the memory through the front panel. In the run mode, the address counter is driven by a free running clock. The clock determines the CW speed and is controlled by a potentiometer on the front panel.

A duration timer controls the address counter. When it is low (normally), it inhibits the address counter from being toggled by the clock, and holds the counter at address zero. When it is time for an identification, the duration timer goes high and allows the address counter to count. The timer then falls low (indicating that the identification is over) and resets the address counter. It is the duration timer which determines whether the identifier is identifying or not.

The duration timer is controlled by a three minute timer. This timer does two things: If the repeaters have not been used for three minutes, upon key-up the timer will send a pulse to the duration timer to initiate an identification. Additionally, if the repeater remains on the air, the timer pulses the duration timer every three minutes.

The three minute timer is controlled by two identical sense and latch circuits. The sense and latch circuits go to the push-to-talk lines of the two repeaters. If either of the push-to-talk lines is grounded, the three minute timer is activated. If the duration timer is high when a push-to-talk line is low, the latch on the respective sense and latch circuit is set, which grounds that push-to-talk line to keep the repeater on the air. When the duration timer goes low the latch is reset, letting the repeater drop.

A power supply feeds the electronics, but when power is lost, the memory is switched to internal batteries.

The schematic of the identifier is shown in Fig. 2. The memory consists of a 2102 RAM. The 2102 is an nMOS integrated circuit and has TTL compatible inputs and output. The chip has ten address lines necessary to access 1024 bits. When a particular address is selected, whatever is present at the D_{in} terminal is stored in that location when the read/write (R/W) line goes low. When the R/W is high, whatever was previously stored will be present at the D_{out} terminal when that address is again selected.

The oscillator utilizes an 88 mH toroid coil with two secondary windings. The audio outputs of the identifier are low impedance. With the component values specified, the tone is 1 kHz.

The address counter consists of three 7493 four-bit binary counter chips. The reset lines are tied together and go to the complement of the duration timer.

The clock is a 555 square wave generator. Another 555 is used as a monostable multivibrator for the duration timer. When the input is pulsed, the output is a pulse of predetermined width (5 to 60 seconds).

A unijunction transistor is used as the three minute timer in conjunction with Q3 and part of U3.

The latches are RS flip flops. The reset lines go to the duration timer's output, so the latch outputs are held low until the duration timer goes high, whereupon the set line may go low if the push-to-talk line is low. When the latches are set, Q1 or Q2 is turned on and holds up the respective repeater. When the duration timer goes low, the latches are reset again.

The step control goes to an RS flip flop used as a debouncer, which toggles the address counter. Bit zero of the address is monitored on the front panel by an LED.

The power supply uses a full wave rectifier to an LM309K regulator chip. Three "D" cells in series provide emergency power for the 2102.

Construction

All of the parts used in the identifier are readily available. All of the integrated circuits used are sold by James Electronics. All transistors except Q4 are general purpose NPN silicon and can be bought in bargain packs. The transistors used for Q1 and Q2 should be rated for whatever current the push-to-talk line of the repeaters requires. Q4 is a unijunction and is sold at Radio Shack as #276-111. The diodes are all general purpose silicon and can be bought from bargain packs, with the exception of CR1 and CR2, which should be germanium and capable of passing 70 mA. The oscillator coil is a centertapped 88 mH toroid coil and can be obtained from M. Weinschenker. Two windings of about 25 to 50 turns should be added to the toroid for the outputs. The power transformer is Radio Shack #273-1384. The components used in the timing circuits (particularly the capacitors) should be high quality units.

The prototype was built on a patchboard type of printed circuit board using Molex sockets and jumper wires. Point to point wiring using integrated circuit sockets on vectorboard should work fine. Particular care should be taken to make ground and Vcc lines out of heavy bus wire, with extensive bypassing with .1 uF capacitors. The logic is not being used very fast, but the chips will respond to pulses of several nanoseconds in length, necessitating good rf construction practices. The unit was built into a Radio Shack plastic box with aluminum cover, but it would be better practice to use an all metal enclosure to keep rf out.

Adjustments and Programming

Programming the identifier is a simple matter. The address counter counts up from zero at a constant rate. A zero in a location produces no tone and a one produces a tone. As the counter counts from zero up, a tone will be generated whenever a one is encountered. Since the identifier rests at location zero, a zero must be programmed in that spot, or the repeater will have a constant tone on it. A dit should be one location long, and a dah three. A single zero should follow dits and dahs within a character, and three zeros should follow each character. Characters at ends of words should have seven zeros after them. Table 1 shows the desired encoding for a typical repeater call. As can be seen, "DE WR3AFM" requires only 83 bits out of the 1023 available, so much longer identifications will fit into the memory.

To program the memory with the desired code, apply power and wait for the LED to stop flashing. Backing off the ID time control will stop it. When the light remains on, the address counter will be at location zero. Flip the mode switch into the program mode. To write into the memory, the write button must be depressed with the Data In button down for a zero, and up for a one. A zero should be written in location zero. Push the step button, and the LED should go out, indicating that the counter is now at location 1. Program a one, and proceed on in this manner until location 83 is programmed. It should be noted that there is no way to go back a count, so if a mistake is made the procedure should be started over. A number of zeros should always be placed after the message to give leeway to the duration timer. Put the mode switch back to run and push the ID button. Set the speed control for the desired speed, and then adjust the ID time control so that the counter resets about five seconds after the ID is done. If a mistake is noticed, hit the ID button again, but place the mode switch into program just before the location where the mistake is located. This makes it unnecessary to step through the entire ID when a mistake is near the end. The counter remains where it was before it is placed into the program mode. After programming a message, tie a push-to-talk line low, and measure the time between identifications. Adjust the 1 megohm trimpot for the desired time — nominally three minutes.

Table 1. Example of programming a typical ID: "DE WR3AFM."

Results

After wiring, the only problem encountered was one of the Vcc lines being too small and poorly organized. After remedying this problem, the identifier had no other problems. After the unit was in operation about a month the speed began to slowly vary. Replacement of the components in the clock circuit fixed this problem. The identifier is located in the bottom of a 450 MHz repeater cabinet, next to a 150 MHz repeater, in a building with dozens of 150 MHz and 450 MHz repeaters. There has been no problem with rf getting into the identifier, even though it is constructed in a plastic case. The identifier has been installed for several months and has been working continuously on the Baltimore Amateur Radio Club's 146.07/146.67 and 444.35/449.35 repeaters. The batteries have not been replaced, and they have been successful in retaining the memory when power failures have occurred. It generally takes between five and fifteen minutes to program the identifier. BARC repeater users have been listening to the CW as it spouts notices and comments. If nothing else, this type of identifier makes users cognizant of the fact that the tones actually say something, and are not something to be constantly ignored, as is the case with too many repeaters across the country. ■

Parts List

CR1, CR2 – germanium diodes, 70 mA
Q1, Q2, Q3, Q5, Q6 – general purpose NPN silicon (2N3904)
Q4 – unijunction (Radio Shack #276-111)
R1 – 10k potentiometer with switch
R2 – 1M potentiometer
S1 – DPDT toggle switch
S2 – momentary push-button SPDT
S3, S4, S5 – momentary push-button SPST
S6 – SPST mounted on R1
T1 – 88 mH centertapped toroid coil with two 50 turn windings added
T2 – 6.3 volt power transformer (Radio Shack #273-1384)
U1, U2, U3, U6 – 7400 quad NAND gate
U4, U5 – NE555 timer
U7, U8, U9 – 7493 four bit binary counter
U10 – 2102 1k static RAM memory
U11 – LM309K voltage regulator

CONTESTS

from page 17

counties or bands. They may be worked on different bands in each county for point credit only. Mobile stations contacted on a county line count as one contact but two or more multipliers. Portable stations that change counties during the contest may be worked for both point and multiplier credit from each new county. Fixed stations may be worked by other fixed stations only once during the contest regardless of bands. Fixed stations may be worked, however, by mobile stations each time the mobile station changes counties or bands. Repeat contacts between mobile stations are permitted as long as they are on another band or at least one of the mobiles has changed counties. KL7 and KH6 are considered DX and maritime mobiles are considered fixed stations for scoring purposes.

EXCHANGE:

RS(T), county and state (country for DX). Mixed mode contacts are permitted, but at least one station must be on SSB.

FREQUENCIES:

Suggested frequencies are plus or minus 10 kHz of following: 3.935, 7.240, 14.290, 21.390, 28.580 MHz. No credit for contacts on county hunter net frequencies of 3.943, 7.238, or 14.336 MHz is allowed.

SCORING:

Contact with fixed US or Canadian station = 1 point; contact with DX stations = 5 points; contact with a mobile station = 10 points. The multiplier is the total number of US counties plus Canadian stations worked. Take credit for a county only the first time it is worked. A county does not count again even if worked again on a different band, but a Canadian station counts each time it is worked. The final score is then the total number of QSO points times the total multiplier.

LOGS:

Logs should include the date and time, the station worked, the report exchanged, county, state, band, claimed points (1, 5 or 10), and each new multiplier should be numbered. Check sheets are not required but would be appreciated on all scores over 100,000 points. Summary and log sheets are available free for a #10 SASE or SAE and appropriate IRCs from: James L. Willingham KØARS, Route 1, Bevier MO 63532. All entries should be received by KØARS by June 1, 1976 to be eligible for awards. DX entries should use air mail.

AWARDS:

Plaques will be awarded to the highest scoring fixed US or Canadian station, DX station, and first and second highest scoring mobile stations. Certificates will be given to the top 10 mobile and fixed stations in the USA and Canada, and to the highest scoring station in each DXCC country. Only single operator stations are eligible for awards; multi-operator certificates will be awarded as merited. A station may enter as both fixed and mobile, but with separate scores. Winners will be announced in the MARAC Newsletter and at the 1976 Independent County Hunters Net Convention (to be held in July '76).

ZERO DISTRICT QSO PARTY

Starts: 2000 GMT
Saturday, April 17
Ends: 0200 GMT
Monday, April 19

The contest is sponsored by the TRA-ARC of Iowa State University. Stations outside of the zero district will exchange reports with stations within the zero district only. Zero district stations may work anyone. Any station may be worked once on each band, on each mode. If a mobile station changes counties, he may be worked again — so be sure to look for mobile stations changing counties.

FREQUENCIES:

3570, 7070, 14070, 21070, 28070, 3900, 7270, 14300, 21370, 28570, 3725, 7125, 21125.

EXCHANGE:

RS(T), QSO Number and ARRL section. Zero district stations will also send their county along with the ARRL section.

SCORING:

Zero district stations: Multiply the total number of contacts by the total number of different zero district counties, foreign countries, and ARRL sections. Non-zero district stations: Multiply the total number of contacts by the total number of different zero district counties worked.

ENTRIES:

To compete — logs, claimed score and SASE (for results) must be sent to: TRA-ARC, WAØTKK, B406 Wilson Hall, Ames IA 50013 no later than May 14th. Appropriate certificates will be awarded.

TWO METER ALL MODES CONTEST

Contest Period: 0300 to
0700 GMT Sunday, April 18

This contest is sponsored by the York Radio Club and Global Research and is open to all radio amateurs, worldwide. Any 2 meter contact is valid except for the use of repeaters other than OSCAR. Use all modes: SSB, CW, AM, FM, SSTV, RTTY, or FAX.

EXCHANGE:

RS(T) and state.

SCORING:

Score one point for each completed two way contact. A multiplier of 1 per mode will be given for every mode worked with a minimum of 5 contacts per mode. Example: A station working 5 contacts on AM, 5 on CW, and 5 on SSB would have a multiplier of 3. Final score is the QSO points times the final multiplier.

LOGS:

Logs should show your name, call, address, state, and input power. For each station worked, include their call, state, and RS(T) sent and received. Show your total score, sign the logs, and submit to: Phil K9DTB, c/o Global Research, PO Box 271, Lombard IL 60148. Logs should be postmarked no later than May 8th for scoring.

AWARDS:

All entries submitting logs will be listed in the YRC Circuit Board and will receive a 3 month complimentary subscription. The first place total score in each category will receive a Bicentennial certificate and a prize from Global Research. Second place totals in each category will receive the Bicentennial certificate. Categories: Mobile — any mode or power; Portable — any mode or power; High power — 100 Watts or more; Medium power — 51 to 99 Watts; Low power — 50 Watts or less; OSCAR — 2-10 meters.

Any questions concerning rules can be answered by K9DTB (Phil) at 312-279-4658. The decision of the contest committee is final.

PACC CONTEST

Starts: 1200 GMT
Saturday, April 24
Ends: 1800 GMT
Sunday, April 25

This year's contest is again sponsored by VERON in Nederland and is open to all single and multi-operator stations. Use all bands from 160 to 10 meters, but please keep the lower 10 kHz of CW bands and upper 25 kHz of phone bands free. General call is "CO PA"; PA/PI/PE stations will call "CQ PACC."

EXCHANGE:

RS(T) and QSO number starting with 001. Dutch stations (PA/PI/PE) will also send a 2 letter code indicating their province. The possible provinces are: GR, FR, DR, OV, GD, UT, NH, ZH, ZL, NB, LB, YP.

SCORING:

Each QSO counts three points. Each station may be worked only once per band regardless of mode. Final score is the total number of QSO points times the sum of all worked provinces on each band (max 72).

AWARDS:

Certificates go to the highest scoring stations in each country and district. (A certificate will go to each call area in the US, Canada, New Zealand, Brazil, Australia, Japan, Chile, Russia and South Africa.)

LOGS:

Logs should show: date and time in GMT, station worked, QSO number sent, QSO number and province letters received, multiplier column for each band (only show a multiplier the first time it is worked), and points. Logs must be sent to VERON Contest Manager PAØDIN, PO Box 1166, Arnhem, The Nederlands, postmarked not later than June 30, 1976. Each log must be signed and indicate that the participant has observed the contest rules as well as all regulations of amateur radio in his/her country.

FOR SWLs:

Show information exchanged between PA/PI/PE *station and other station.* Each station heard counts 1 point; otherwise scoring is the same.

Put That AM Rig on FM

Bring the old AM rig out of retirement and put it on FM for about $10.00 or less. It's one of the cheapest ways to get on FM that I know of, especially if you already have a rig. As most of us know, with an AM transceiver, receiver slope detection can receive FM at a readability comparable with an AM signal of just about the same strength. On the other hand, in transmitting FM, an advantage is that comparatively simple means may be used to generate an FM signal.

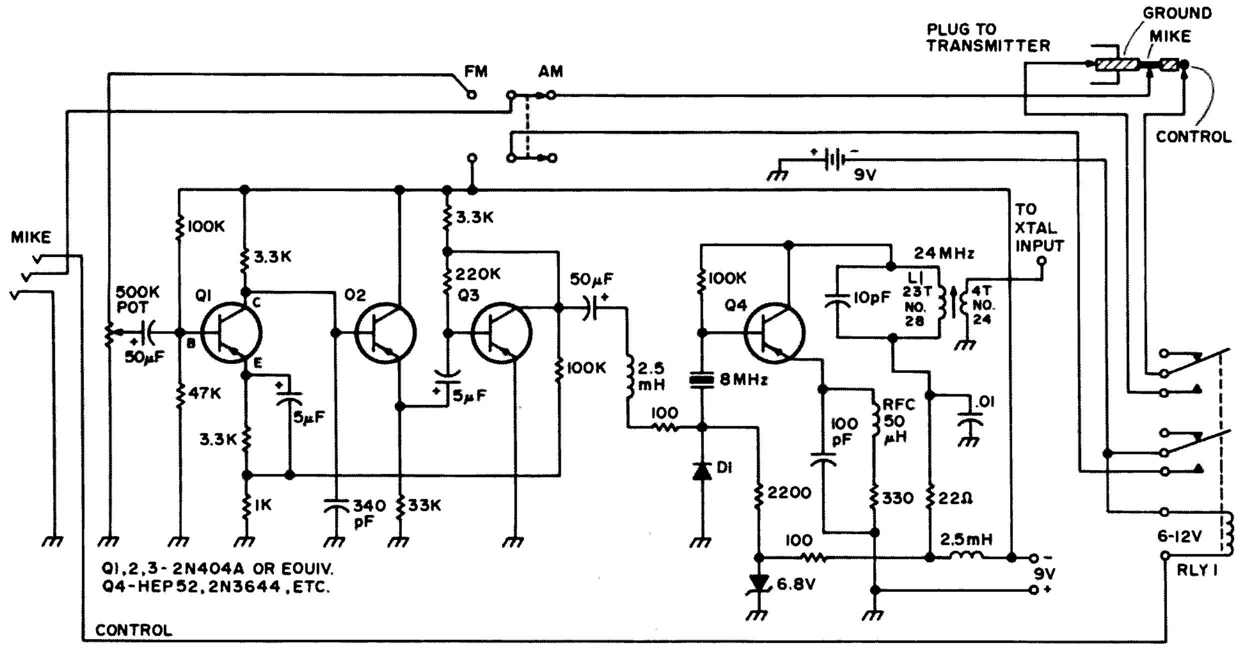

Fig. 1. Circuit of FM adaptor.

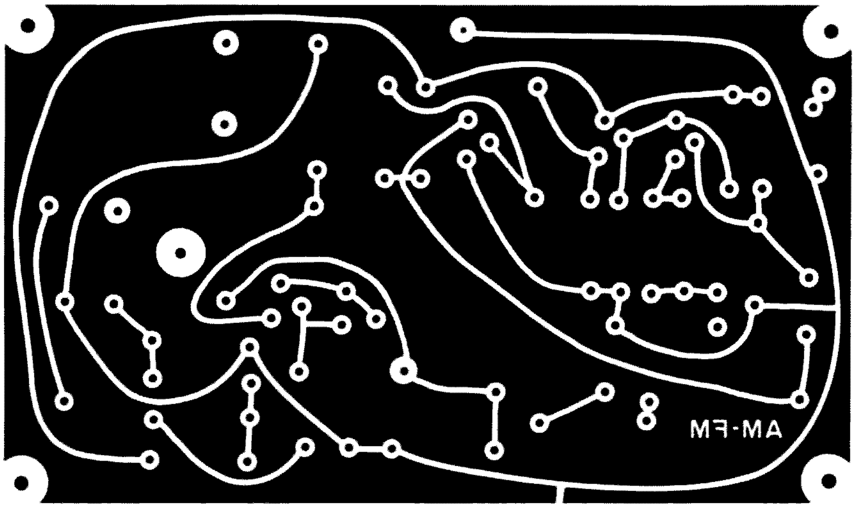

Fig. 2. PC board pattern.

Because a VHF transmitter multiplies the original oscillator frequency several times, only a small amount of deviation at the oscillator frequency will be required to produce narrow band FM. The frequency modulator contains a microphone preamplifier, driver amplifier and 8 MHz crystal oscillator at 24 MHz output. The audio from the modulator drives a variable capacitance diode in the crystal oscillator. I used a silicon switching diode. Frequency multipliers in the transmitter increase the deviation to about 8.5 kHz at the output frequency. A microphone and control with push-to-talk cable plug in the transmitter's microphone jack. It carries the push-to-talk line, but no audio unless the switch is in the AM position. Deviation can be reduced for narrow band FM by adjusting the audio pot on preamp. Use a hi-Z microphone. Results are worth it; I have been using my FM modulator 6 months, working several 2 meter repeaters and signal reports have been good. ■

A Carrier Operated Relay (COR) for Your Receiver

Fig. 1. Schematic of the COR. Q1 could just as well be an MPF102 or any other N channel JFET. Q2 should be a 200 mA, 30 volt transistor. RY1 is a 26 volt telephone type relay. The LED is nothing more than an indicator I hung on as an afterthought.

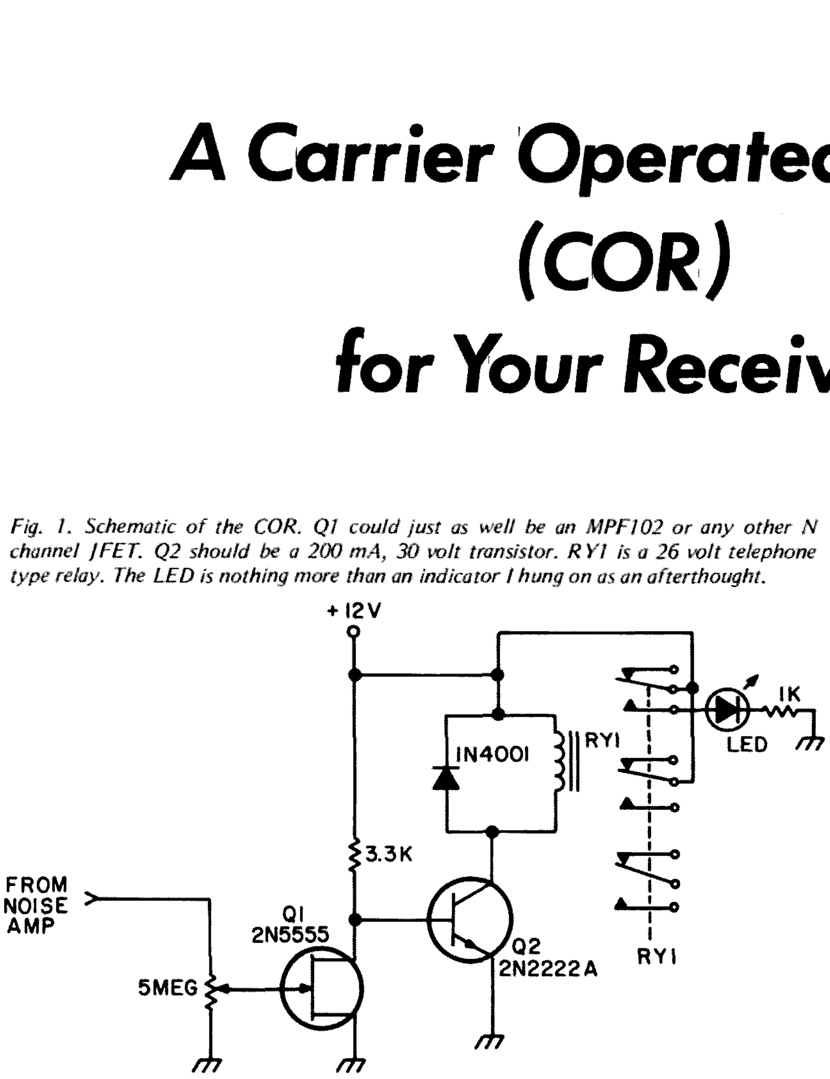

Fig. 2. Connection for a TA141A type receiver is shown.

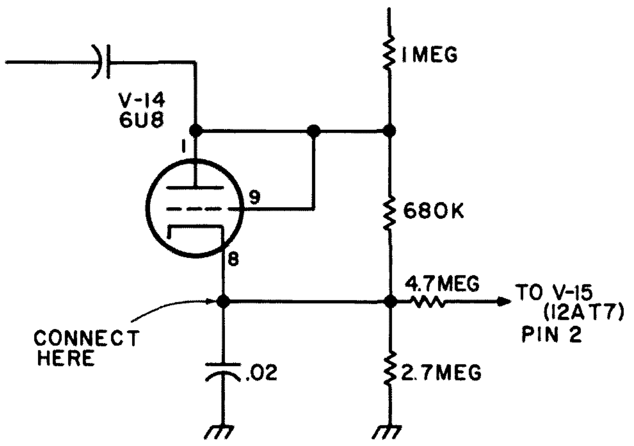

I have a Motorola T44 which I have built power supplies for, mounted in a rack and now use as a base station. I now want to use that equipment as a 450 MHz repeater but, of course, the receiver has no COR. I could have bought a squelch relay kit made for the radio but, besides adding more tubes to the radio, it would cost money.

I retreated to my junk box and came out with a few JFETs, some NPN 300 mA transistors and a telephone type relay. The book of schematics I have for Motorola gear says the squelch relay is connected to the cathode of the noise rectifier on the 450 radios. A measurement there with a VTVM showed a voltage that rested at +2 V dc squelched and swung to about −12 V dc with a carrier present. This seemed compatible with my FETs so I put together the circuit in Fig. 1.

The cathode voltage is brought out across a 5 meg pot. The circuit starts loading and affecting squelch action when a value much below 2 meg is used. The JFET gate is taken off the arm of the pot. When the receiver is squelched, the slight positive voltage causes the FET to conduct, which in turn holds Q2 off. When a carrier is received, the gate swings negative turning Q1 off and Q2 on, thus closing relay RY1. By the way, the relay I have is marked 26 volts but I find it works fine at 12 volts and only draws about 40 mA.

Conclusion

This circuit is perfect for all of you who like to correct, improve, or add to magazine circuits. There are hundreds of ways this could be improved or modified but I wanted it simple, cheap and workable and this fits those needs admirably.

For those of you with T44s, I include Fig. 2 which shows where to hook up the COR. ■

A $5 100 Watt Amplifier

Over the past few months there have been two antenna-building workshops sponsored by the Northern Alberta Radio Club in Edmonton. At each workshop 15 two meter beams were constructed. The spacing and element lengths are fairly standard, but the construction methods might be unique. The original intent was to construct a small beam that could be easily disassembled for portable use; however, a number of fellows required a simple base station antenna, so materials and methods were chosen to suit both needs. The following outlines the materials and methods used.

Materials

The boom is constructed from 1/2" Type M (very thin wall) copper tubing, at least 48 inches long. A piece 6" to 8" longer would be required for ideal mounting methods, to be discussed later.

The elements are made of 1/8" diameter brass rod. This is relatively expensive, about 15¢ per foot, but the amounts required are not excessive. The element lengths are 40", 38", 36" and 35-1/2".

The gamma match is made of a 4-3/4" length of 1/16" diameter brass brazing rod (or copper), a 10 or 12 mmfd disk ceramic capacitor (12 preferred), a removable shorting clamp of your design, and a small stainless steel worm gear hose clamp.

RG58 coaxial cable is recommended if the antenna is for portable use.

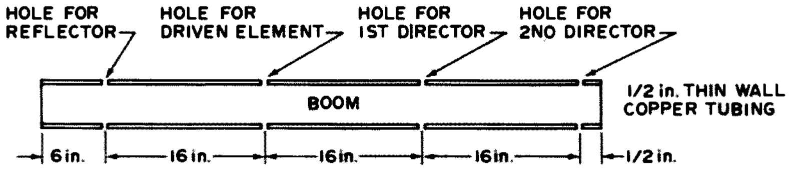

Fig. 1. NOT TO SCALE

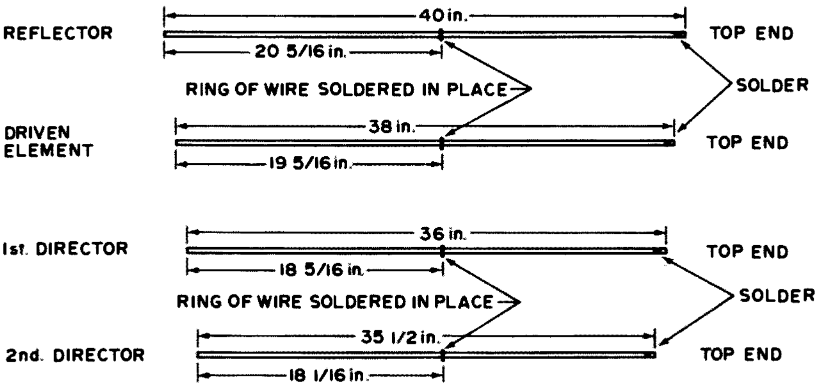

Fig. 2.

Construction

The boom is prepared by drilling 1/8" diameter holes on 16" centers. This can be accomplished by careful use of a drill press or by a hand drill. Since most workshops do not have a drill press, the second method is described.

First, draw or scribe a circle around the tubing at each of the four element positions, i.e., on 16" centers as shown in Fig. 1. A tubing cutter, used with care, will do a good job. Alternatively, wrap a sheet of paper carefully around the tubing so that it doesn't spiral and the edge will form an accurate guide for your pencil.

Once all four lines have been drawn, lay a straight edge on the top of the tubing and using a center punch, mark the 4 hole locations. These 4 holes can now be drilled but DO NOT DRILL THROUGH BOTH SIDES OF THE PIPE.

Again, with reasonable care, mark the holes on the bottom side of the tubing using a straight edge. Drill 4 holes. With a minimum amount of luck these holes will line up with the first set!

The elements should be cut to the lengths shown in Fig. 2, and a small piece of wire wrapped around and soldered to each element as shown. This is required to keep them from falling through. For permanent installation the elements may be soldered to the boom. (I have used the "gravity system" on my base station antenna for the past year with good results.) A spot of solder on the top of each element ensures that they are put in the right way up. Note that the wire ring is *not* in the middle of the elements. When disassembled, the elements are stored inside the boom. Two small corks will ensure their staying put!

The gamma match is very simple as can be seen in Fig. 3. The measurements should be followed fairly closely. The shorting clamp can be made in any number of ways.

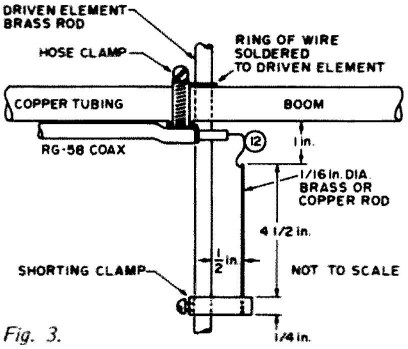

Fig. 3.

A solid block of brass can be drilled to accommodate the driven element and the gamma rod with a set screw to hold them in place. A simpler method is to fold a piece of brass or copper over both rods and place a clamping bolt in the middle. It is important to have something that can be easily loosened if the antenna is to be readily dismantled.

The hose clamp, which connects the shield of the coaxial cable to the boom, should be as close to the driven element as possible. Ideally, the cable should be dressed along the boom past the reflector and then down the support mast. A number of fellows have dropped the cable between the driven element and the first director and they report good results. Figs. 4(a) and 4(b) show the two methods with 4(a) being the preferred.

For base station operation I have fastened the boom directly to the boom of my triband beam as shown in Fig. 5.

Cost

The cost of materials should be slightly less than \$5.00. If a group can get together and make 15 antennas with 48" booms (15-3/4" element spacing), this will prove to be the most economical since both copper tubing and brass rod come in 12 foot lengths. Brass brazing rod comes in 36" lengths and could be spliced up to the 40" and 38".

Test Results

At a recent two meter antenna-testing workshop, this beam provided a 10 dB gain over a reference dipole. There is no doubt in the 10 dB value, but there may be some doubt in the efficiency of the reference dipole used. In any case, the antenna works well. ■

Build A 220 MHz Repeater

One must first have a radio to build a repeater. I chose to use my Midland 220 rig. This radio is ideally suited to repeater construction as it is in three separate sections: the exciter, receiver and power amplifier. I separated the sections and then each was installed in its own aluminum chassis, except for the power amplifier, which was mounted on the rear panel of the main chassis. The chassis I'm using to house everything is a Bud AC-415, which is 17" wide, 10" deep and 2" high. The small chassis that the receiver and exciter are mounted in are 7" wide, 5" deep, and 2" high.

Some minor changes were necessary to separate the receiver from the rest of the radio as the receive crystal and trimmers are on the exciter board. This was solved by etching a small PC board and mounting the parts on it and locating it with the receiver. The channel selector switch can be eliminated along with all the parts on the exciter board that were for the receiver. The power amplifier heat sink can be removed (carefully) and discarded, as the rear panel of the main chassis makes a much better heat sink. Throw away the pilot lamps as they are current hungry, drawing over 100 mA. Without them the receiver draws about 90 mA squelched.

The power amplifier is probably the trickiest section to work with. No problems were encountered mounting it; however, it does require a little bit of tweaking to get power out of it when it's mounted. Some stretching of coils and repeaking of capacitors took care of that problem. Expect about 15 Watts or more when using a 12 volt auto battery, and up to 20 Watts with a well regulated 14 volt power supply.

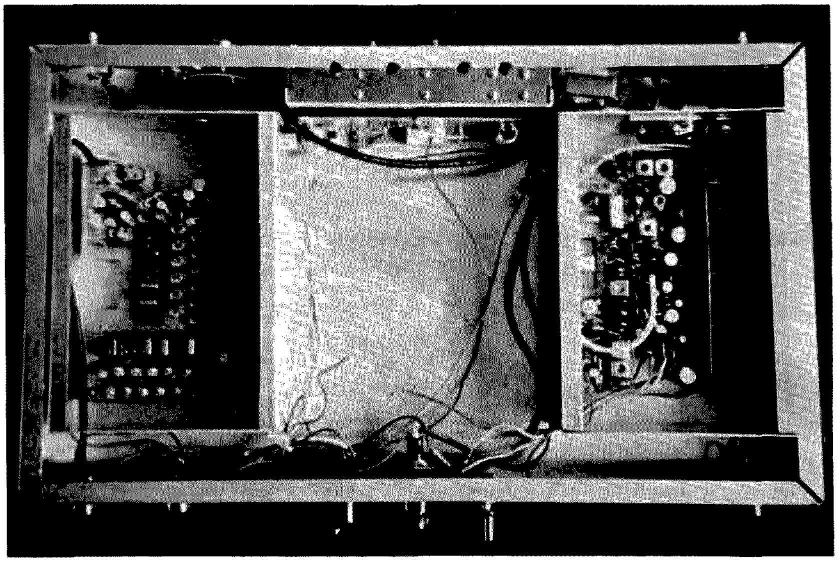
At the present time I'm using what will eventually become an operating repeater as a duplex rig, on the West Hartford 220 repeater featured on the June 1975 cover of *73*.

Referring to the photograph of the top view, the enclosure on the left is the exciter board, the one on the right is the receiver board and in the center rear is the power amplifier.

The sensitivity of the receiver is quite good as it comes from the factory, being .5 uV or better for 20 dB of quieting. Careful retuning will improve this only slightly, so a preamp seemed desirable.

I realized that finding material on the 220 MHz band is at the least difficult, and checking through a few publications confirmed this fact. I definitely wanted a preamp, so I was forced to adapt existing designs for two meters. An excellent design that can be made to work on 220 is in the *FM and Repeaters* book that the ARRL publishes. The schematic and board layout are on page 180. The coils are the only changes needed to make this preamp work quite well on 220. Change L1 to 4 turns, No. 18, 1/4" dia., 1/4" long. Do not change the tap location. L3 remains the same except for the diameter, which is 1/4".

Another change which can be done to the preamp is to reverse the foil pattern so that the parts may be mounted on the same side. Then two small pieces of double-sided PC board can be used to shield the input and output. See the 225% PC board. Tune the preamp as explained in the book.



The transmitter is as about as good a circuit I've ever seen performance-wise. Midland is definitely being modest when they claim 10 Watts output. Before I even started on this project, the rig was putting out 18 Watts at 14 V dc input, checked on a Bird Thruline. An automatic swr shutdown circuit is also incorporated in this rig, but I have bypassed it by not running the rf output on the relay board. This was so I could eliminate the eventual problems one encounters with relays by replacing it with a solid state keying circuit. I have already keyed the transmitter into an open line at high power and no damage to the finals occurred. This is probably due to the fact that Motorola power transistors are used, a 2N6081 being the final.

Since I wanted this to be a really good sounding transmitter, I also modified the modulation stage to produce true frequency modulation, rather than the phase modulation employed in the rig. This is not as hard

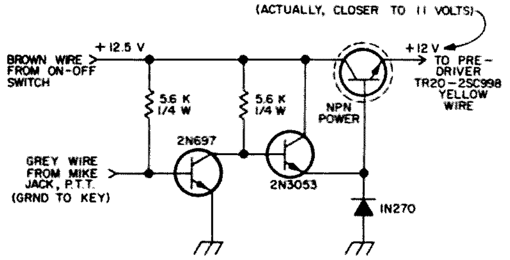


Fig. 1. Solid state transmit control for the Midland 220 repeater. Tie red wire from transmitter board (27) to B+ – this keeps the exciter operating continuously. The output from TR21 is about 100 mW, so running it all the time doesn't hurt, since the TR20 base has a 100Ω ½ W to ground to present a load. Also, the lower voltage on TR20 hasn't decreased power; I still get 15 Watts out at 12.5 volts (automobile battery).

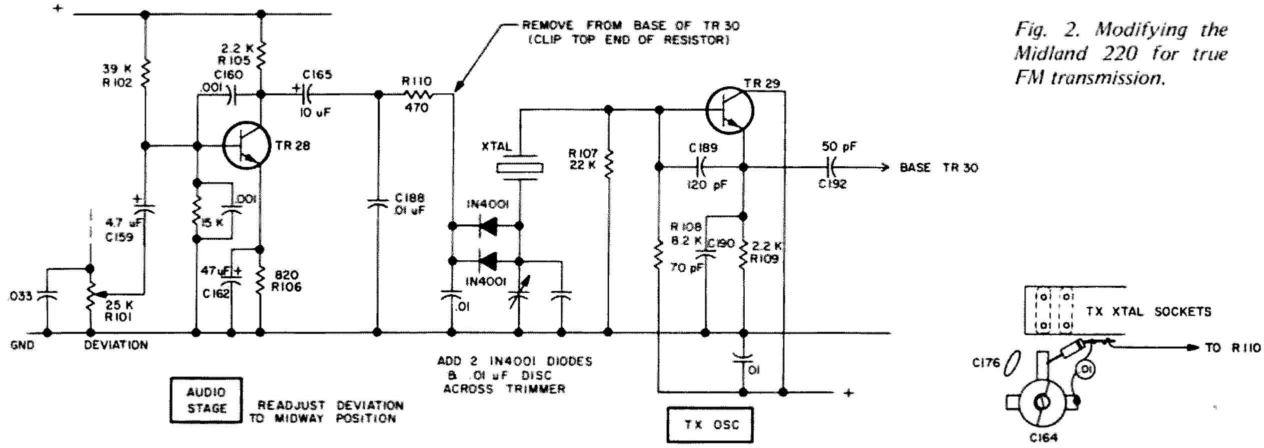

Fig. 2. Modifying the Midland 220 for true FM transmission.

to do as one would think. Since a repeater has only one transmit frequency, shortcuts can be taken. Add two 1N4001 diodes, a .01 uF disc capacitor, and clip one resistor lead and there you have it! The accompanying diagram shows where to make the changes.

I mentioned two paragraphs back that I have converted the radio to solid state keying. The circuit that I am using is also shown; parts and layout are not critical. Any NPN transistor will work, but just in case, I mounted the power transistor on the main chassis. So far it hasn't even gotten warm, even when keyed for long periods. I mounted the other parts on a piece of .1" grid perfboard and mounted the board on the back panel near the power transistor. This circuit keys the B+ to the pre-driver transistor only. The finals have B+ on them continuously. Also, I wired the exciter to operate continuously. Connecting the red wire from the exciter board at point 27 accomplishes this.

The microphone jack and accessory jack were both brought out and mounted on the front panel. The accessory jack is used to feed in the audio from my Touchtone pad. The power switch, a fuse holder, the audio and squelch controls and a 1/4" phone jack were also mounted on the front.

BNC connectors were used for the antenna connections, the chassis mount type being UG-1094s. I plan to change these to type N in the future. Number 14 insulated wire is used for the dc power leads. About six feet should be enough for any installation.

The space in the center of the transmitter and receiver is for the master logic board control circuitry, which is currently under construction. This will be presented in a future article.

If anyone would like to duplicate the layout of this project, scale drawings and additional details are available from the author. Please send a large SASE. Let's get more 220 repeaters on the air to show that we do want to keep the band. As the old saying goes, "220, USE IT OR LOSE IT." ■

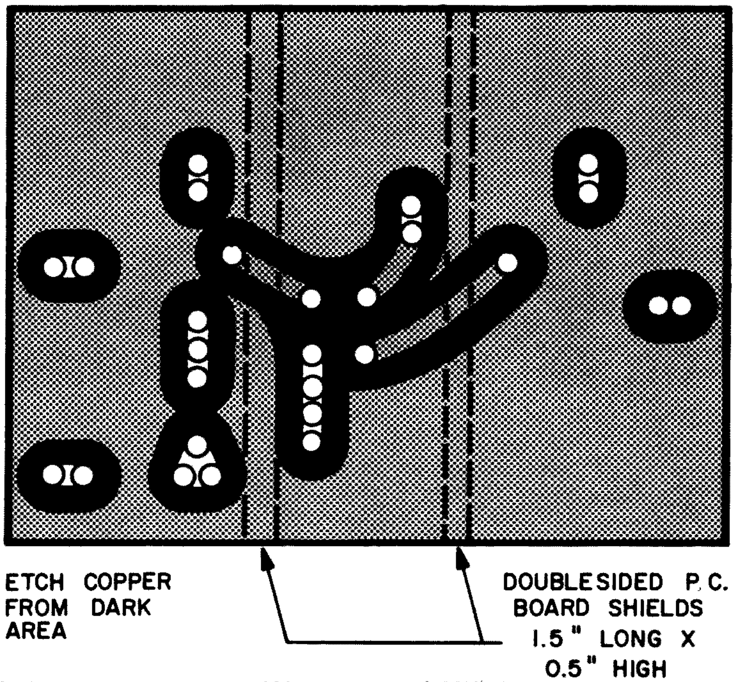

Fig. 3. Foil and component side, 220 MHz preamp (225%). Parts location same as in the FM and Repeaters *book.*

Carrier Indicator for Your Regency

In mobile and high-noise environments, it can be difficult to distinguish between carrier-off and full quieting conditions. If you have ever tried to key a repeater and heard nothing, only to hear the squelch close up a moment later, you know what I mean. Having noted (and envied) the carrier-indicator feature in Icom equipment as well as in commercial gear, I decided to see what

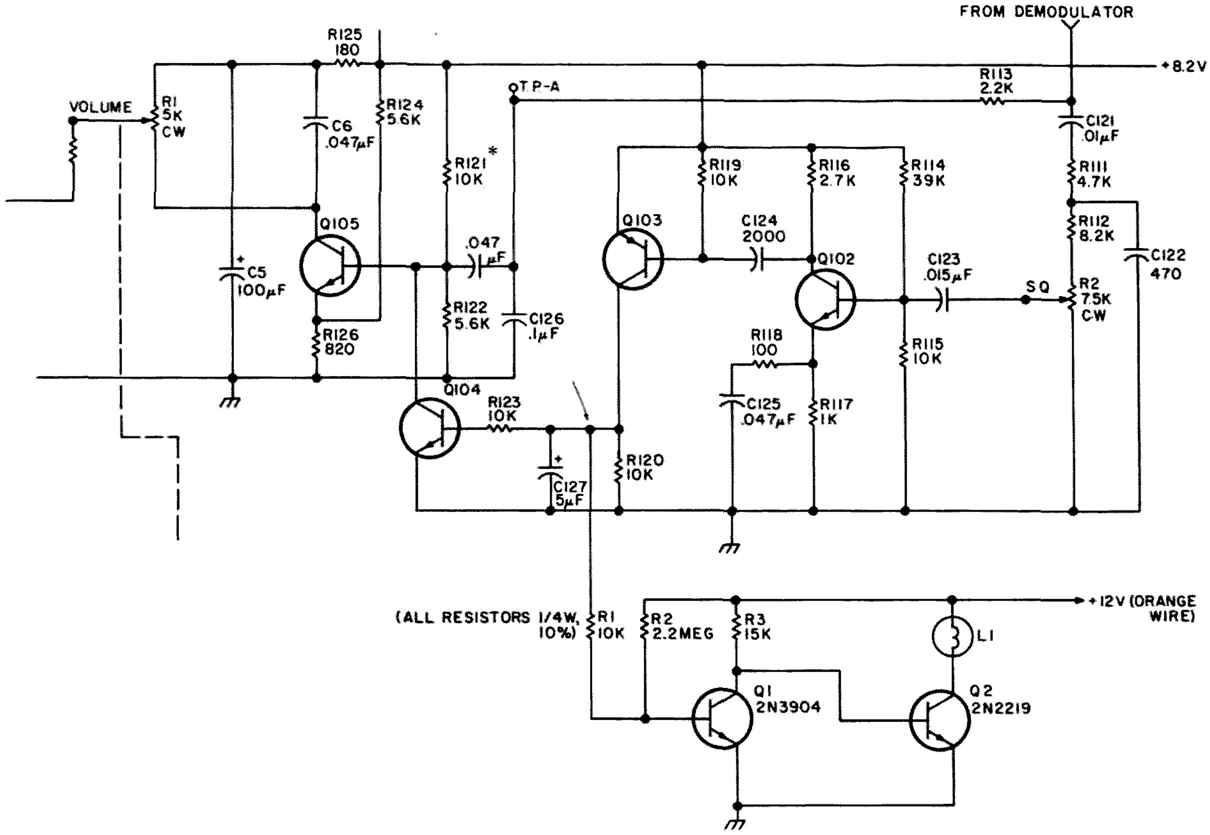

Fig. 1. Regency HR-2B squelch circuit, with inverter and lamp driver.

could be done with my Regency unit. However, this circuit is equally applicable to other rigs with similar squelch circuitry.

This modification requires no additional holes or otherwise permanent disfiguration which would reduce resale value. No etch cutting or board chopping is required. The unit may be restored to its original factory condition within a few minutes. The circuit works very well, and last but not least, it's cheap and simple!

The circuit is shown in Fig. 1. It is essentially nothing more than an inverter, Q1, and a lamp driver, Q2. A small amount of base bias is applied to Q1 to prevent low level noise spikes from turning the lamp on when no audio is heard in the speaker. Also, when Q1 is off and Q2 is on, the lamp lights fully — never at partial brilliance. This is because the biasing arrangement is such that the transistors bias themselves into saturation or cutoff with no in-between states. So even a noise spike that gets through to the speaker will illuminate the lamp momentarily. Yet the squelch control may be set at "critical squelch" and you will still have "crisp" lamp operation.

The Regency squelch circuit is quite straightforward (see Fig. 1). Demodulator noise produced during the no-signal condition is filtered and applied to a noise amplifier, Q102, through the squelch pot. The noise amplifier output is then ac coupled to dc amplifier, Q103, whose output is filtered and dc coupled to the base of transistor switch Q104. The switch simply grounds out or opens the input to the first audio stage, thus shunting noise to ground yet permitting audio to pass through to Q105.

When noise is present, it is amplified by Q102 which turns Q103 on fairly hard. Residual ac ripple is removed by filter capacitor C127. This positive dc voltage, about three volts, turns on the switch, Q104. When ac noise disappears with signal, Q103 is turned off, which in effect grounds the base of Q104, thereby turning it off and permitting audio to pass.

Since one squelch switch is already in use, why not add another one for the lamp? With proper isolation (provided by R1), squelch operation should be unaffected. However, the squelch switch is normally turned on, so an inversion is provided by taking the collector output of Q1 to drive Q2. Thus, the lamp turns on only when carrier is present. As mentioned earlier, R2 provides a small amount of base bias which the squelch signal must overcome in order to turn the lamp on. In this way, short negative-going spikes which would not be heard in the speaker will not illuminate the lamp either. Lastly, Q1 is direct-coupled to the base of Q2, whose collector load is the lamp.

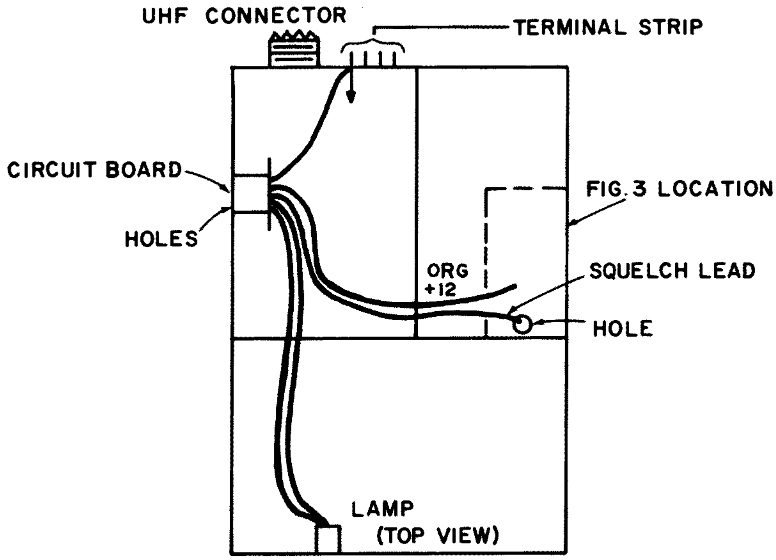

Fig. 2. Layout.

Component Selection

I had always wondered why designers select a particular transistor over another, equivalent transistor. In doing this project, I found out why. First, the devices have usually been used by the designer before, so he is familiar with their characteristics from experience. Second, they are available (in my case, junk box). Third, their general specifications (beta, collector current, power dissipation) are adequate for the task. For Q2, a low V_{CE}(sat) was desirable, since I wanted the maximum voltage drop to be across the lamp, not the collector-emitter junction. R1 was chosen because it would provide both adequate isolation and base current for Q1. R2 was chosen experimentally from observing the lamp. R3 was chosen to minimize current through Q1 and to drive Q2 into cutoff or saturation. As for transistors, I simply used a good general-purpose device for Q1 and a high-current, good gain device for Q2. However, almost any NPN transistors will work, although some may require slight value adjustments in order to work well.

Installation

Since my Regency is synthesized, I don't need the channel window illumination. I removed the orange +12 volt lead from the lamp and installed a lampholder in the hole so conveniently provided by Regency. To this I connected the collector lead from Q2 on one side and +12 volts on the other side. I ran the orange lead to the left rear corner of the radio, near the UHF connector (see Fig. 2). Here I mounted the transistors and resistors on a small piece of experimental circuit board. There are two unused holes here, so I used them to mount the standoffs and then the circuit board. You may need flat washers here, since the holes are rather

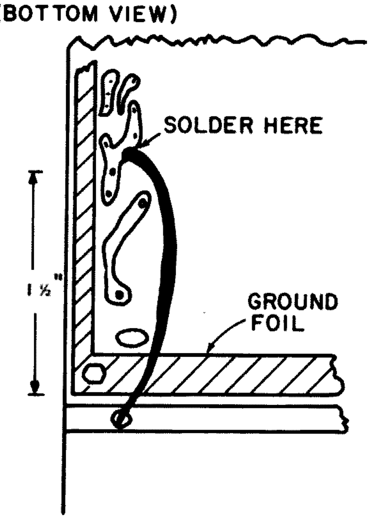

Fig. 3. Foil location detail.

large. Grounding is available at the rear apron terminal strip.

The lead for the squelch switch is provided by running a lead across the board to the foil side through a hole in the frame between the transmitter and the receiver circuit boards. Find the foil that joins R120, R123, and the positive side of C127 (see Fig. 3). Solder the lead here.

You may use the lamp originally provided for the backlight, but it turns on and off rather slowly, so I left it mounted in its clip in case I ever need to restore it to service. I used a Dialco cartridge lamp no. 39 rated at 14 V and 80 mA. Mine has a clear lens. However, the 2N2219 will dissipate .8 W and carry 800 mA, so almost any lamp will work. You could even use it to drive a COR for repeater applications! ■

Long Distance Call Eliminator

by
William J. Hosking W7JSW
8626 E. Clarendon
Scottsdale AZ 85251

Our autopatch in Phoenix is an open one and anyone with a tone pad on his radio can use it. The telephone switching center that our line works through was unable to provide us with a tone dialing line without direct long distance dial capability. While this has not been a serious problem, there have been many "malicious" long distance calls, such as to time/temperature in New York City.

I wanted a simple method which would eliminate the direct dial long distance calls without doing a major rebuild of our entire autopatch. One recommendation I received was a digit counter which would allow only seven digits to be dialed. While completely feasible, the idea required more hardware and modifications to the system than I wanted to make. As I was cogitating on the situation and also monitoring the patch, I heard a guy with a marginal signal and weak tones bring up the patch and then get a misdial because his first tone digit was not strong enough to make Ma Bell's equipment function; consequently the dial tone remained until his second tone came along. It took a while to sink in, but in time I realized that the dial tone and the first digit dialed exist simultaneously for a few milliseconds. Therefore, if I decoded the dial tone with a half a second or so delay and also decoded a "1," the combination could be used to hang up the patch phone anytime a "1" was dialed as the first digit of a phone number. The idea is shown in block diagram form in Fig. 1.

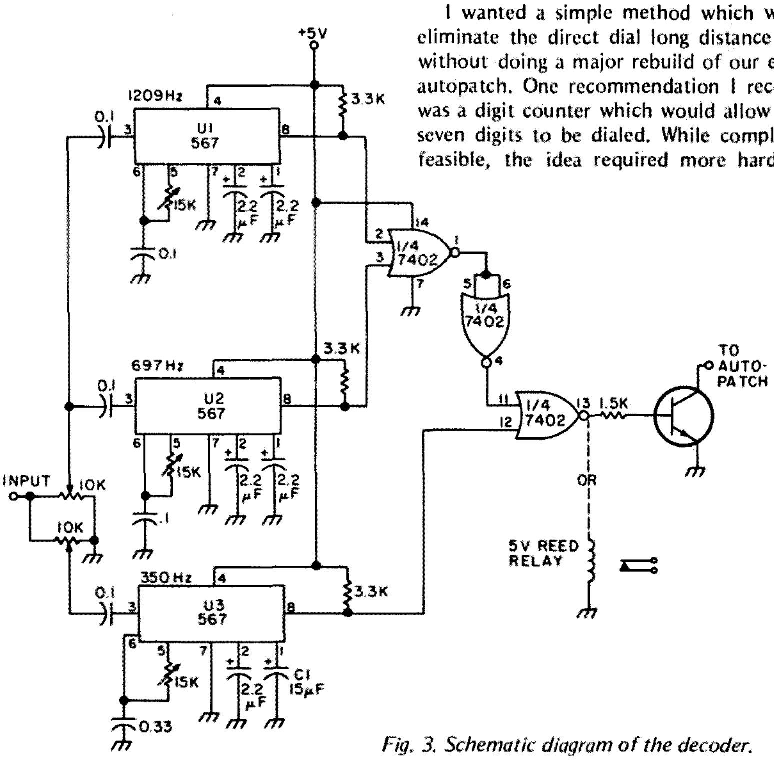

Fig. 3. Schematic diagram of the decoder.

Circuit

A quick check of my reference books showed that Ma Bell is pretty well standardized on a dual tone composed of 350 and 440 Hz for dial tones. Since both tones are well below the normal tone dialing frequencies, I decided to only decode one of the dial tone frequencies – 350 Hz. To decode the "1" I needed two more decoders, one for 1209 Hz and one for 697 Hz (see Fig. 2).

Now, referring to Fig. 1 again, when the 350 Hz dial tone and the 1209/697 "1" tone are present simultaneously, the output of the AND gate goes high thus operating either a transistor switch or a relay which in turn shuts down the patch.

The actual circuit is shown in Fig. 3 and consists of only three 567 tone decoders, a 7402 gate, and either a transistor or a relay. The decoders are connected normally for

567s except for U3 which has added capacity on the output filter. The added capacity causes the device to remain on for a few milliseconds after the dial tone has gone away. Note that C1 on U3 sets this delay and might have to be adjusted slightly to meet individual system needs.

Construction

The unit can be built almost any way you want. I found that, with minor modification, the circuit board for my Single Function Control Decoder (*73 Magazine*, March 1976) works very nicely. The boards are available from Contact, Inc., 35 W. Fairmont, Tempe AZ 85281.

Installation and Operation

First (I mean after the smoke test), using a frequency counter connected to pin 5 of U1, set the frequency to 1209 Hz. In the same manner connect the counter to U2 and adjust the frequency to 697 Hz. Then connect to U3 and adjust for 350 Hz. Now you are ready to install the device in your autopatch.

A sample of how I connected ours is shown in Fig. 4. The power source is a 309k five volt regulator connected across the 25 volt dc relay line. By the way, when using 309s don't neglect the recommended 0.22 uF from input to ground – they sometimes do strange things without that capacitor. The audio input connection is important as it must contain both telephone and receiver audio. I use the audio output from the patch to the transmitter. Then I used a transistor to open the "off" reed relay in our system as shown in Fig. 4. Another method is shown in Fig. 5 using a normally closed relay contact to open the main phone relay in a system.

As it is anytime when using 567s for decoding, they are very level sensitive. Be very careful when setting input levels – otherwise your patch might get falsed off. This is the only application right now where I have 567s in service without an agc amplifier preceding them and I may well yet add one. I hope this cuts down your phone bill – it did ours. ■

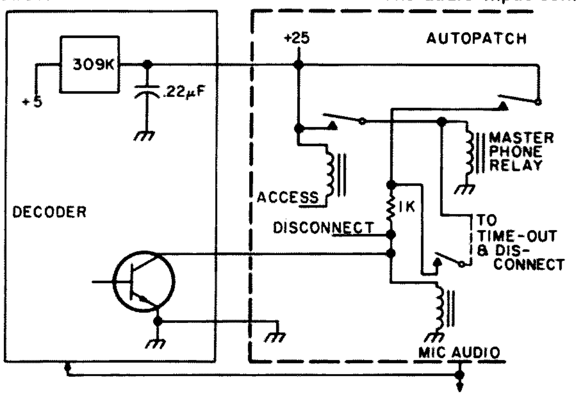

Fig. 4. Interconnection used in the WR7ABQ autopatch.

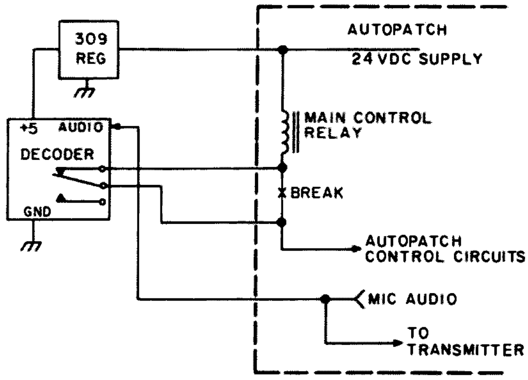

Fig. 5. Alternate interconnection using a relay having normally closed contacts.

Repeaters in Paradise

Visitors from Capt. Cook (who discovered the islands) to James Michener have all agreed that paradise is that group of islands centered at approximately 20 degrees north latitude and 158 degrees west longitude. The Hawaiian Islands – now the State of Hawaii – certainly qualify as paradise if such can exist on this earth. Now, the Emergency Amateur Radio Club of Hawaii has constructed a "heavenly" system of two meter repeaters to add to the other attractions of this famous, historic and beautiful place.

I spent the last two weeks of June vacationing on the island of Oahu at Waikiki Beach, and having heard that two meter repeaters were available in the fiftieth state, I took my trusty TR-22 along. Much to my surprise I was able to work from Kauai to Hawaii Island from Waikiki by accessing the Diamond Head repeater.

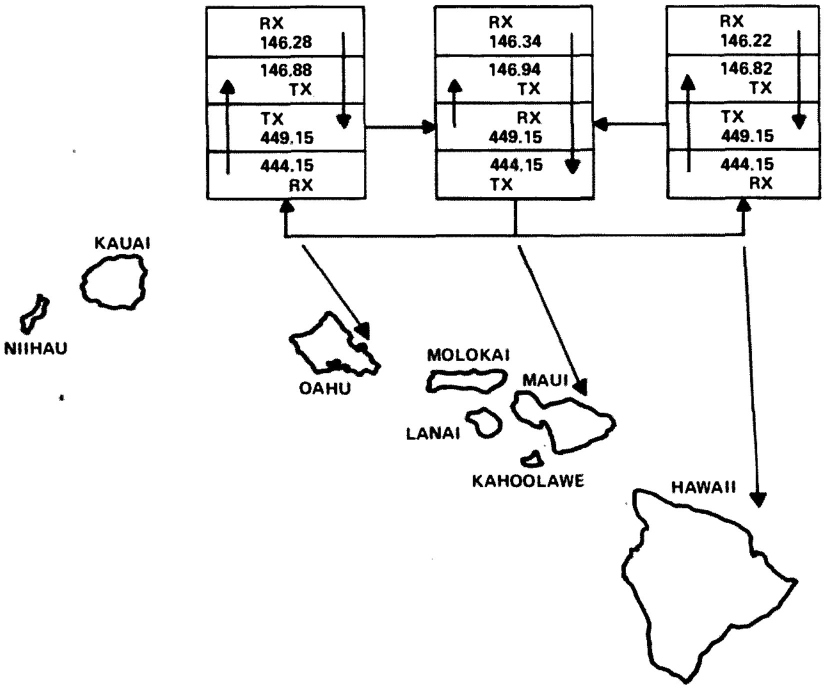

Fig. 1. Repeater link interconnection.

The secret of the Hawaiian system is a series of 450 MHz links which interconnect the repeaters on Oahu, Maui and Hawaii islands. This means that a station accessing the major repeater on his particular island is also able to access the major repeaters on the other two islands via 450 links, simultaneously. The interconnection scheme is shown in Fig. 1.

The Diamond Head repeater operates from the crater rim of that famous landmark on a frequency pair of 146.28/146.88 MHz. This is the major repeater for the island of Oahu and is linked to the other islands by the 450 MHz links previously mentioned. There is also a local repeater operating at 146.16/146.76 MHz at the University of Hawaii Manoa Campus but this may be discontinued due to lack of activity. We could hope not as it is a very nice repeater and easily accessible from the Waikiki area. There is another local repeater on the western side of Oahu at Ewa which operates on 146.19/146.79 MHz. This repeater is not easily accessed from Waikiki with a handie-talkie, but there are plans to move it to a much higher point in the Waianae mountains approximately 4000 feet above sea level. This should improve access considerably.

The major repeater on the island of Maui is located on an extinct volcano, Haleakala, at 10,000 feet above sea level. Haleakala means "house of the sun" and with that kind of elevation we won't argue the point. The frequency pair for the Haleakala repeater is 146.34/146.94 MHz. The location is so good that it provides an input for base stations on Kauai some 200 miles away. I was able to access it with the handie-talkie from a twelfth floor balcony on Waikiki beach, a distance of a little more than a hundred miles.

The "Big Island" of Hawaii is the site of a 146.22/146.82 MHz repeater.

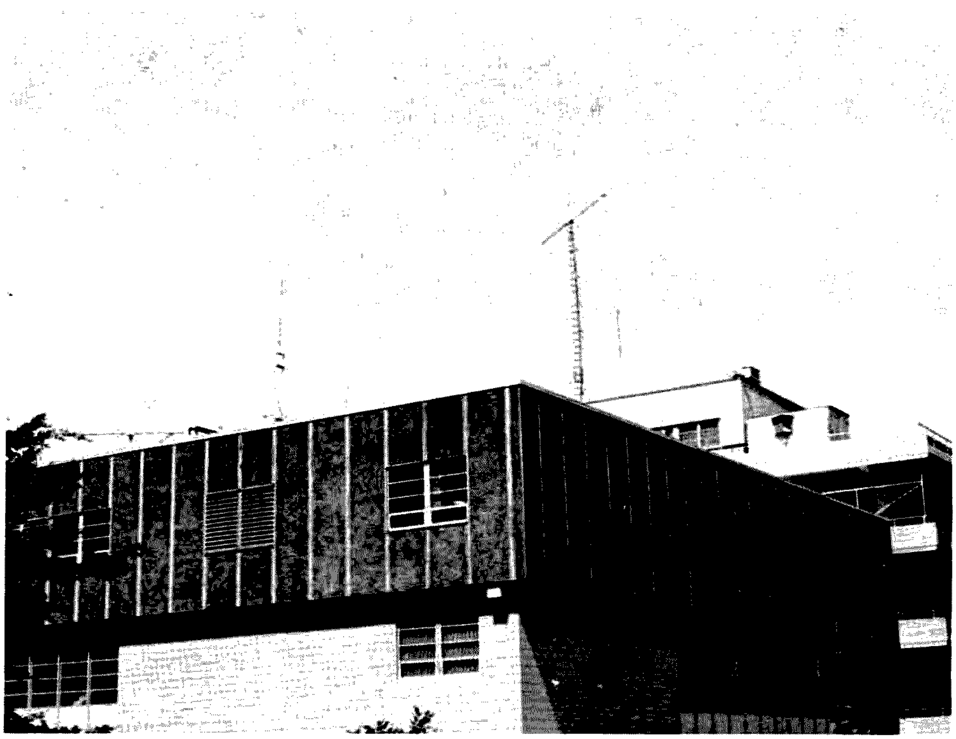
This is located on Mauna Loa, an active volcano, at approximately 8,000 feet MSL. This is the only two meter repeater operating from an active volcano (it has erupted since my visit), and probably holds a DX record for access as well having been worked from the west coast during a band opening — a distance of some 3000 miles. There is a local repeater at Hilo using 146.16/146.76 MHz for operation.

At present, there is no repeater on the island of Kauai, but plans are being made for a 146.04/146.64 MHz machine there to link with the other islands, and a local repeater on 146.13/146.73 MHz according to John KH6BFU at Hanamaulu, Kauai.

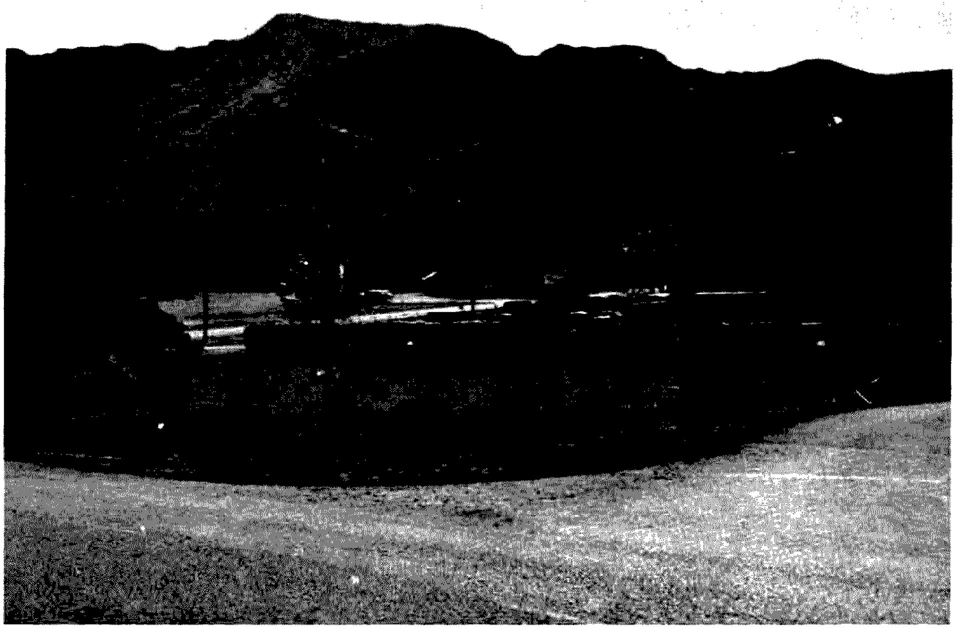
It is interesting to note that the ancient and honorable tradition of calling CQ is being preserved in Hawaii. Whereas mainland operators routinely say "monitoring 76" or "listening 88" to indicate their availability for a call, you will still hear "KH6 - - - calling CQ Diamond Head," etc. Some KH6 stations have switched to the mainland type operation, but many still call CQ, so don't be afraid to do likewise.

In spite of the re-transmission necessary to achieve linking, the audio quality is good. During my stay there the operation was consistent and reliable. It was a real thrill to sit on Waikiki Beach and yak with a fellow ham at Kona about 175 miles away using a handie-talkie. And what a fantastic communications resource in the event of an emergency! The fiftieth state should be proud of its hams.

We would like to credit KH6GBX, KH6GRQ, KH6FNB, KH6BFU and numerous others for information, consideration and abundance of the "aloha spirit" during our visit to Hawaii. ■



Shown above is the Hawaii Institute of Geophysics Building at the University of Hawaii Manoa Campus on the island of Oahu. KH6FOX operates the 16/76 repeater from this location as well as a variety of other ham gear.



This scene is inside the crater of Diamond Head looking toward the south. The 28/88 repeater antenna is located on the opposite rim of the crater.

Simple New TT Decoder

by
William J. Hosking W7JSW
8626 E. Clarendon
Scottsdale AZ 85251

I recently had need of a simple and compact single function control circuit. I wanted it to fit in most commercial or amateur transceivers and decode two numbers from a Ma Bell tone pad. The 567 decoder fit the bill but I didn't need the full seven tones. Three tones would give me the two numbers I wanted.

Connection of the basic 567 tone decoders is right out of the Signetics Data Book. Three of the decoders are used to decode two Touchtone digits. The values shown in the schematic will allow each of the decoders to be tuned over the entire tone signaling range. With this range the decoder can be set to recognize any two numerals in a given row or column on the tone keyboard. In my particular case, I have one set to turn on with a "*" and off with a "#", and another set for "1" ON and "*" OFF.

Circuit

The circuit is shown in Fig. 1. The audio input to the decoder should not exceed about 200 mV. R1, 2 and 3 in conjunction

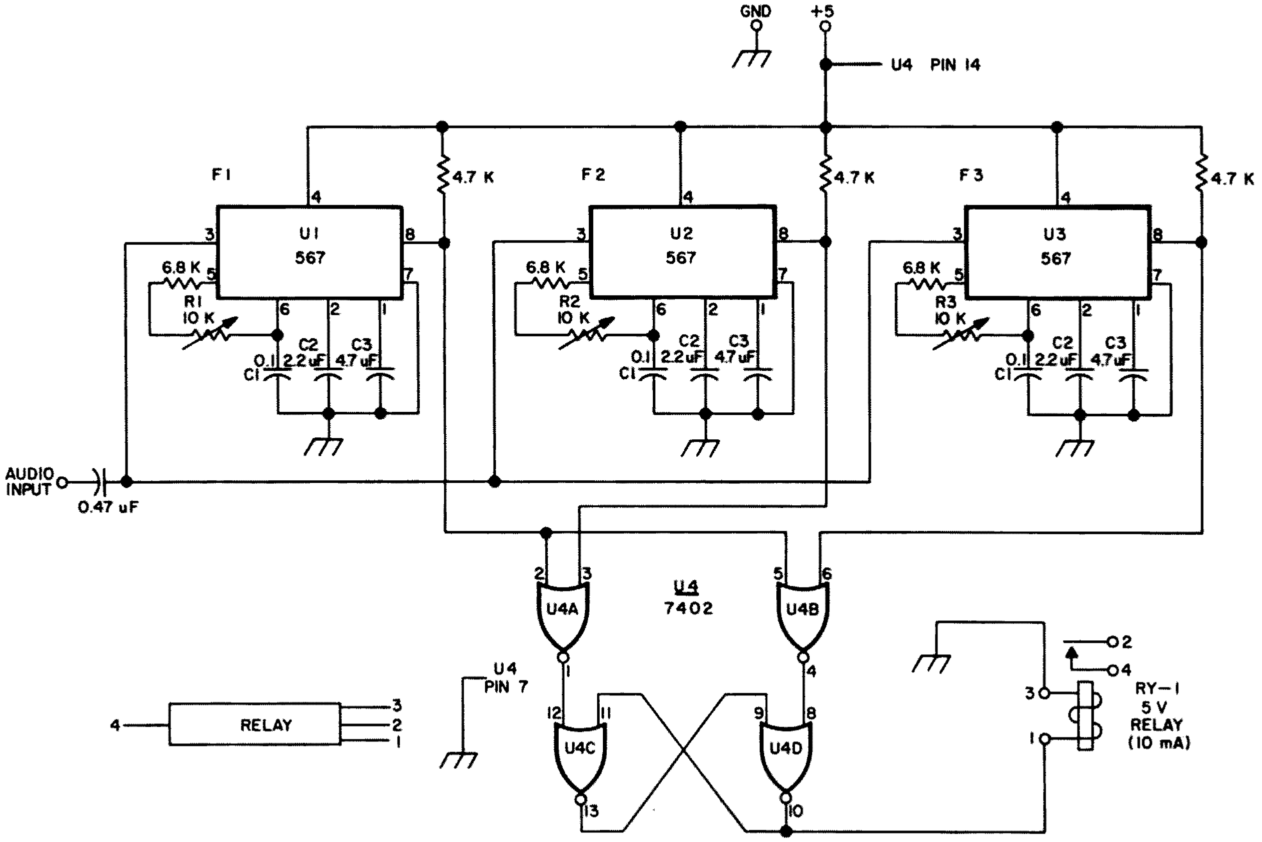


Fig. 1. The complete circuit for the function decoder. F1, F2 and F3 are the required tone frequencies for the desired control numbers. RY-1 on mine is an Electronics Applications Company IA5AH but any 5 volt SPST Reed relay will work.

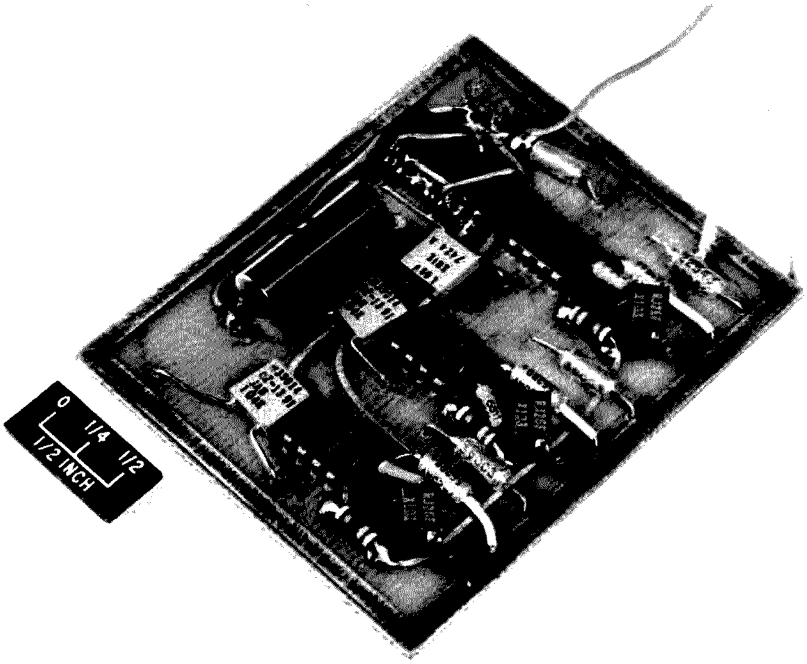


An assembled prototype circuit board. The board is approximately 2½" x 3".

with C1 set the frequencies of their respective 567 decoders. With the values shown the variable resistor will tune the 567s over a range from about 550 Hz to 1500 Hz. C2 is the loop low pass filter and controls the detection bandwidth. I used the 2.2 uF value specified in the application notes and found it works fine. C3 affects the turn-on time and jitter on the output switch. With the value given in the data book I experienced considerable leading edge bounce on the 567 output. Increasing C2 to around 4 to 6 uF cut down the bounce without slowing down the turn-on too much. The output of U1 goes to both decoding gates and this IC sets the common row or column frequency for the two numbers desired. The outputs of U2 and U3 go to U4A and U4B respectively. These 567s are tuned to the frequencies of the second tone required for each numeral. The outputs of U4A and U4B set and reset a latch made up of U4C and U4D. The output of U4D drives a 5 volt low current relay directly.

Adjustment

A frequency counter or accurately calibrated scope is required to adjust the decoder. A chart of the tones is shown in Fig. 2. When the desired numerals have been selected from a single row or column (i.e., 1 and *) then tune U1 to the common tone frequency (i.e., 1209 Hz). This is done by connecting the counter to pin 5 of U1 and adjusting R1 until the desired frequency is read.

In the same manner adjust U2 and U3 to the second tone frequencies for the two numbers desired (i.e., U2 to 697 Hz and U3 to 941 Hz).

Now with a tone pad connected to the audio input and the level set to about 100 mV the relay should turn on and off with the correct tones. With the example I gave, the relay should turn on with a "1" and off with a "*".

Hz	1209	1336	1477
697	1	2	3
770	4	5	6
852	7	8	9
941	*	0	#

Fig. 2. The standard tone frequencies for tone dial systems.

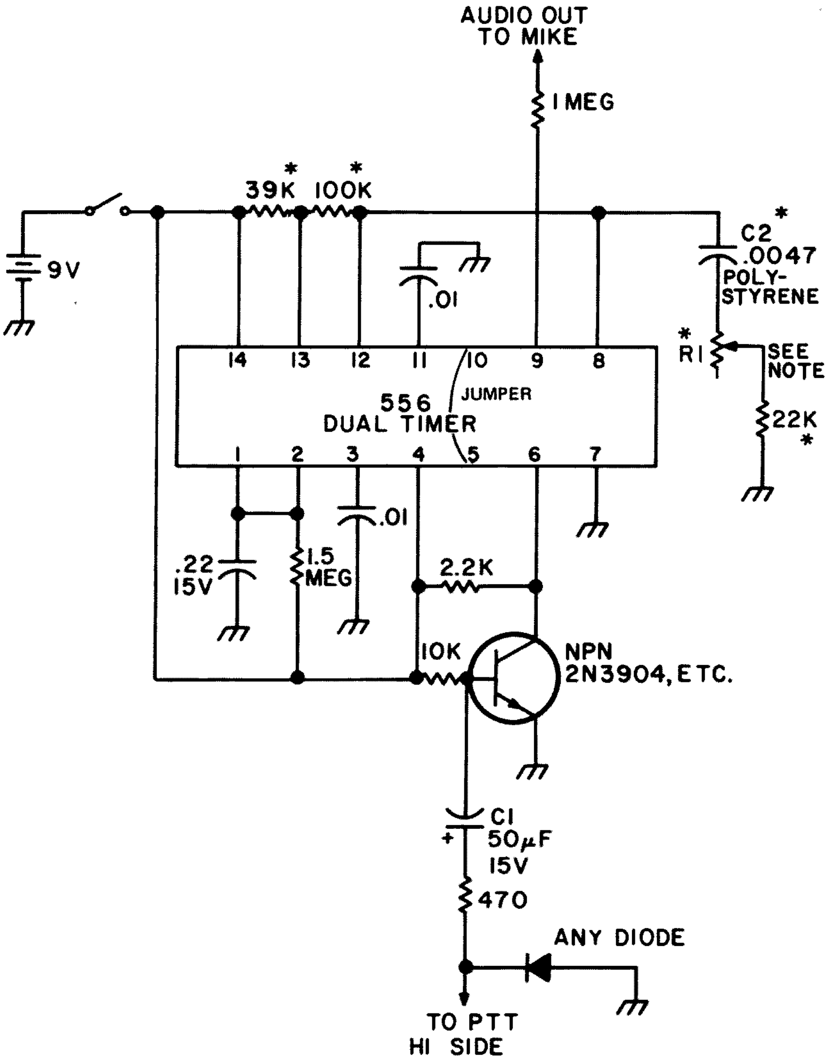
Conclusion

A photo of the completed decoder in its prototype stage is included. The circuit fits my requirements and also fits inside my 450 base station. The board is approximately 2½" x 3". A local group CONTACT, INC., 35 W. Fairmont Dr., Tempe AZ 85281, has etched and drilled PC boards available for the decoder with latch and relay for $5.50. They also sell the decoder wired, tested and tuned to your desired numbers. I have several of these decoders in use in various places and find them quite useful. ■

One IC Tone Burster

by
Lhary Meyer WB6ZUA
Box 379
Fairfax CA 94930

*Fig. 1. R1:15 or 20 turn linear 10k trimmer (Amphenol 3805, etc.). *Cermet or wirewound resistors.*



Needing an 1800 Hz tone burst to access a local repeater, I turned to my faithful junk box. The most likely prospect was a 556 IC dual timer that I got as a free sample from a manufacturer (a great way to get 1 or 2 pieces of a part free, especially if you have a letterhead).

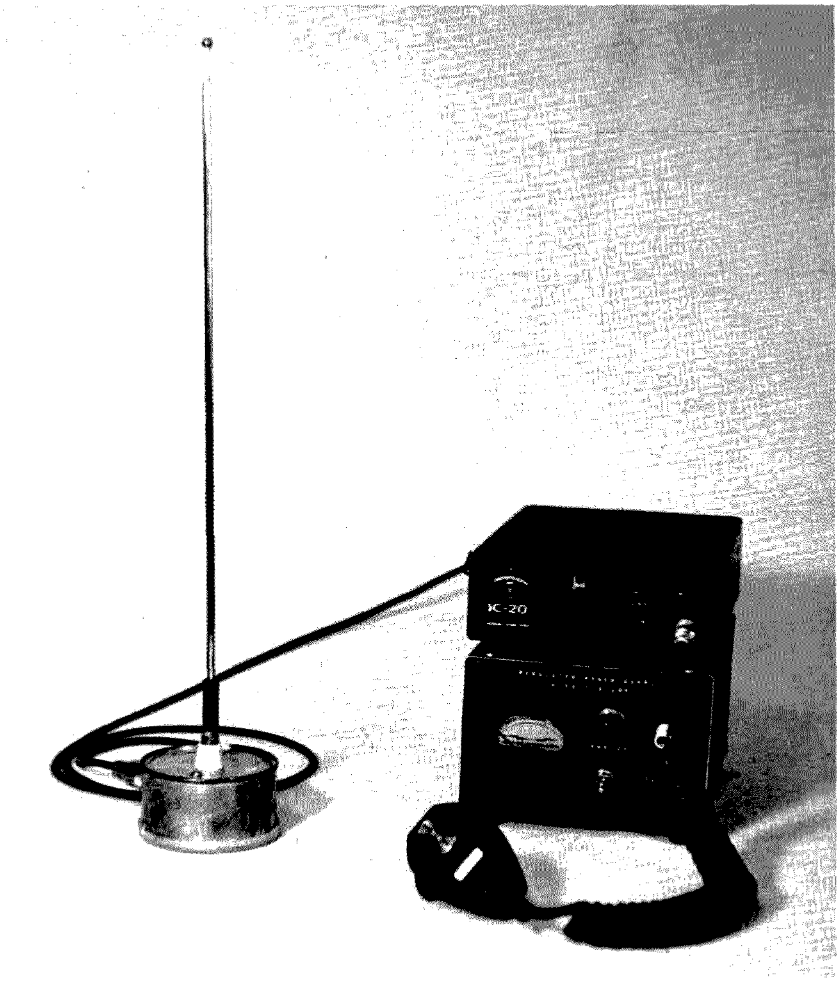
The first half of the IC is used as a monostable with an on time of about 400 ms. The second half is a free running oscillator which is disabled via the low output of timer #1. The NPN transistor amplifies the negative going pulse from C1 to start the cycle when it discharges to ground.

The only part that is not common is the 15 or 20 turn trimmer pot. These run about \$2.50 new from Allied and allow a smooth, stable frequency setting. They produce about a 30 Hz per turn tuning and have a low tempco.

The input voltage and the temperature have little effect on the frequency, but if your repeater has a narrow window the parts should be cermet or wirewound resistors and a polystyrene capacitor. The power for the circuit is not critical. I use a 9 V battery, but 12 V is fine. The trigger input requires +12 V.

Mine is mounted in a small minibox with a male and female mike connector on opposite sides. I included a power switch and with only 11 mA drawn, the batteries last a long time. A switch and a few more pots would give various tones if you need them. ■

The Tuna-Two Traveler



by
Edward R. Spadoni W1RHN
91 Tower Street
Dedham MA 02026

Are you using your 2 meter FM mobile transceiver with battery or ac power supply at the home QTH? Want to move it temporarily away from its present location to the den, without having to reroute the outside antenna? You may want to try it in the living room or bedroom when you're ill or want to be super comfortable, or on the porch or patio on a nice Sunday afternoon. Operate from your motel room after a long drive, whether vacationing or on a business trip. The portable antenna to be described will also give you freedom to find a comfortable spot to operate the rig and still allow you to locate the antenna for best results.

Description

The antenna described here has been used at all of the above-mentioned places, with surprising results. The design and construction was due to the desire for a small, quick to assemble, easy to move around (i.e., looking for a hot spot in a room) type antenna, that can be remotely located from the rig, limited only by the transmission line used. The radiation resistance of a ¼ λ antenna is in the order of 20-30 Ohms under favorable conditions. Most 2 meter FM transceivers want to see approximately 50 Ohms for a load. To help the antenna meet this requirement I introduced a ¼ λ,

RG-58U (53 Ohms) matching section. The transmission line between the transceiver and the antenna can be any reasonable length of RG-59U (73 Ohms) TV type coaxial cable.

Construction

Obtain a tuna fish can or equivalent (approximately 7 ounces), wash well, remove label and drill holes (see Fig. 1). Because the metal is on the thin side, be careful of sharp edges and burrs. Use a 5/8 inch (16 mm) Greenlee punch to make the mounting hole for the coaxial connector. Any telescoping section that will extend between 16 (40 cm) through 25 (63 cm) inches will work. The telescoping section that I used came from an old set of TV rabbit ears. A coupler is needed that becomes part of the telescoping section and is screwed onto the threaded stud of the insulated feedthrough. The coupler was made from 3/8 inch (9.5 mm) diameter aluminum rod. One end is drilled to accept the telescoping section. The other end is drilled and threaded to match the stud on the feedthrough insulator used (see Fig. 2).

Assembly

Most parts came from the junk box, others from the local radio-TV parts store (see Fig. 3 for assembly, and parts list). A replacement CB walkie-talkie antenna from the Radio Shack, catalog no. 21-1156, can be used for the telescoping section. Install the feedthrough insulator onto the can as shown, then the S0-239 coaxial connector with ground lug and associated hardware. The hardware used was 4-40 thread by 5/16 inch (7.9 mm) long screws with lockwashers and hex nuts. Next, make the matching section from RG-58U cable (see Fig. 3). Shape into a coil that will fit inside the can and tape at several places (see photo). Now install inside the can and solder ends of cable to the lugs and coaxial connector. I found a plastic cover of the right size that will fit over the bottom of the can to prevent scratching of furniture, etc. It came with a can of peanuts, a well-known brand and found in most supermarkets.

Final Comments

The transceiver used with the antenna is an Icom IC-20 with approximately 10 Watts output. After attaching the antenna to the rig, I placed the antenna on the hutch in the den, extended the telescoping section to about 19 inches (48 cm) and fired up the rig. The IC-20 has a relative power output meter with a mark that lets you know if you're in the ball park for a 50 Ohm match (this was checked using a known load). The meter indicated that there was a mismatch. By adjusting the length of the antenna, I was able to bring the meter within the proper range. I then tried the antenna on the window sill; this did cause the match to change, but again with a little adjustment

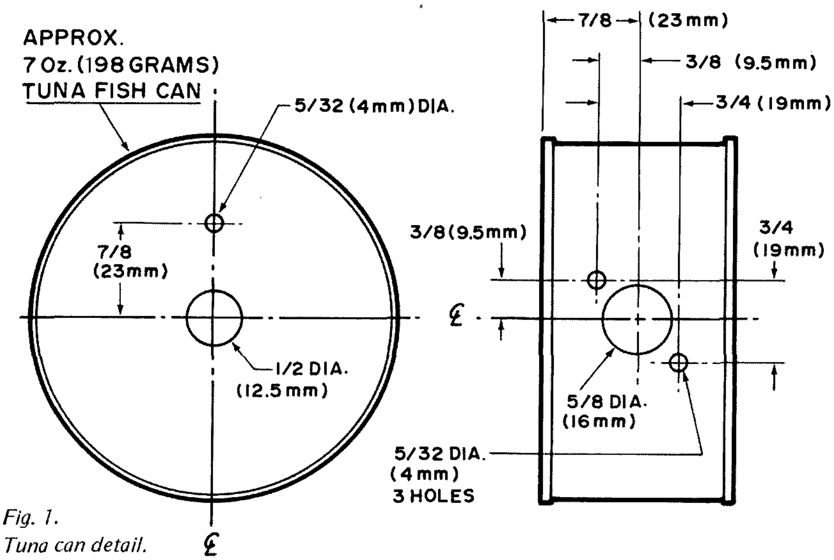


Fig. 1. Tuna can detail.

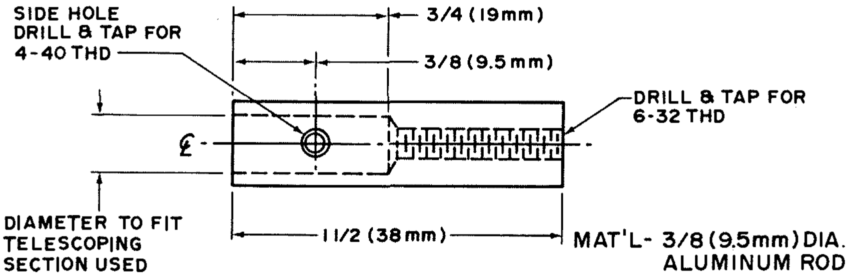

Fig. 2. Coupler.

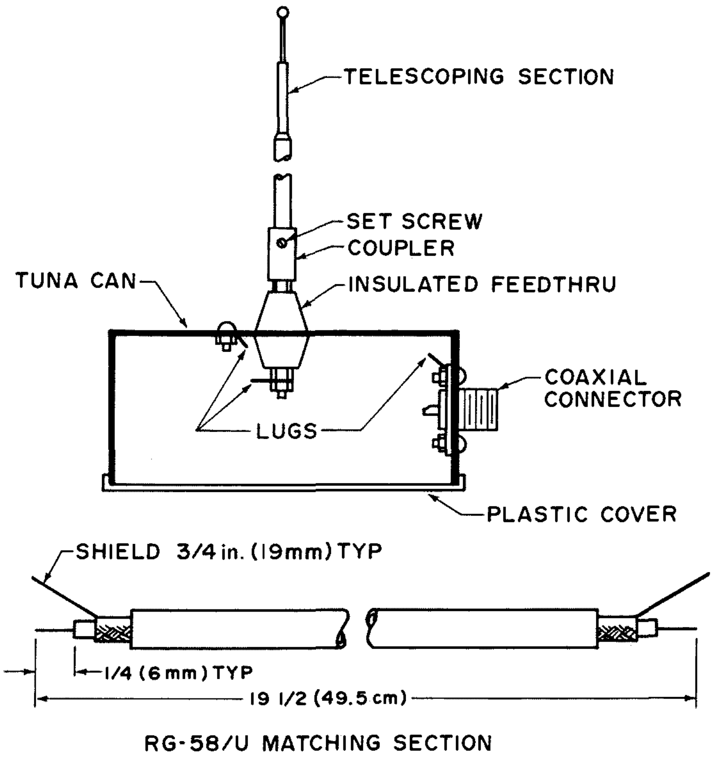

Fig. 3. Assembly. Center conductor is soldered to feedthrough lug and coax connector center.

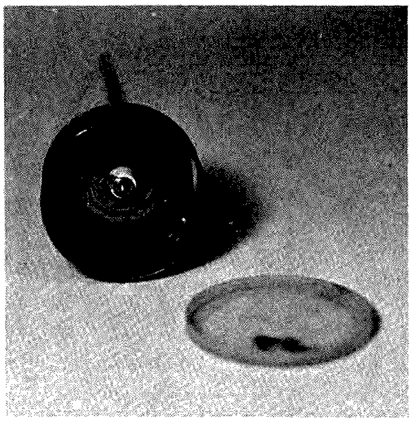
and watching the meter, the mark was reached. I want to note that when the antenna was not operating at optimum setting, repeater and simplex contacts were being made with good results, indicating that it is not a critical adjustment. Most transceivers today have their output transistor stage protected against antenna troubles that may develop (check owner's manual). I connected a Heathkit VHF swr meter into the circuit with the antenna located on the window sill and found that from 146 through 147.69 MHz the swr was less than 1.5:1. With the antenna located on the sill I have been able to work through 5 repeaters in and around the Boston area including Derry, New Hampshire (WR1ABQ rpt.) located about 50 miles away. QSOs up to 25 miles have been made via simplex. This antenna is a good evening or weekend project. Its low cost and ease of assembly will make it worth your while to use or have available if needed. ■



Parts List

QTY	Description
1	Tuna can (refer to Fig. 1)
1	Feedthrough insulator – E.F. Johnson, cat. no. 135-50 (or equivalent)
1	Coaxial connector, type SO-239
1	Telescoping section (refer to text)
3	No. 4 – ground lugs
1	Plastic cover (refer to text)
1	Coupler (refer to Fig. 2)
1	Set screw (4-40 x 1/8" long)

The Mighty TR-22/15

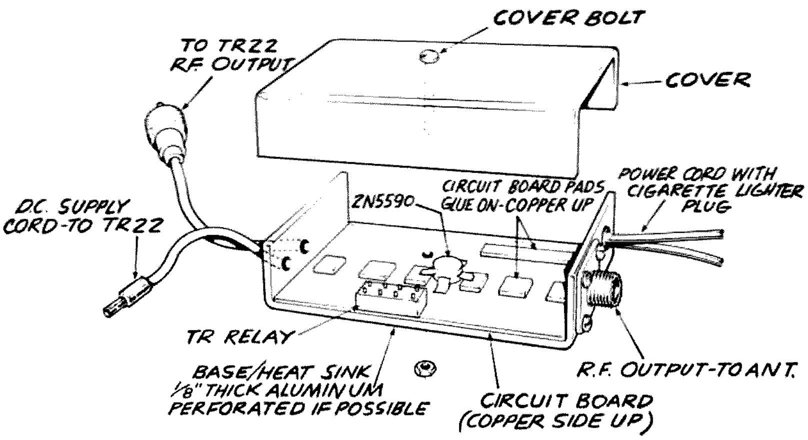


Fig. 1.

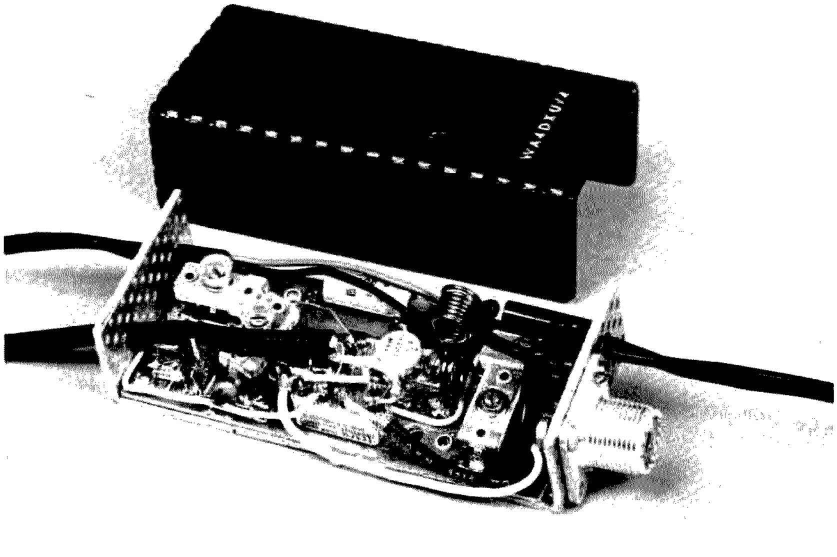

by
Walter W. Pinner WB4MYL
7304 Lorenzo Lane
Louisville KY 40228

Want to add a little more power to your TR22??? Want to make this power package small enough to fit into the microphone pocket??? Want to make the circuit board with tin snips and glue??? YES? Read on . . .

The little amplifier I'll describe is easily constructed, will deliver 15 Watts output with 1 Watt input and can be built for less than $10.00.

The amp fits into the mike pocket of the TR22C nicely and incorporates a dc power plug for the radio. A small 1 inch slit in the mike pocket bottom allows the dc plug and rf input plug to go directly to the sockets on the bottom of the transceiver. The top of the amp has the antenna socket and dc input cable fitted with a cigarette plug. This arrangement provides easy hookup to your car, boat, motorcycle or ??? and when used mobile, both the TR22 and the amp are powered by the external source.

Fig. 1 shows the mechanical construction. An aluminum bottom/heat sink is formed as shown. A piece of copper clad board is pop-riveted or bolted to the bottom cover, copper side up. An aluminum top is formed and secured to the finished amp with a single through bolt. The circuit board is made by cutting copper clad pads with tin snips and gluing with one drop super glue or epoxy as shown in the full size layout in Fig. 2. Fig. 2 also shows the parts placement. All leads

should be cut to the minimum needed length including the compression trimmer caps. Fig. 3 shows the schematic and parts list. The rf transistor has been advertised in *73* at $6.00. Heat sink paste should be used when mounting this transistor and don't get too strong when tightening the mounting nut. Tuneup is simply a matter of connecting the amp to a dummy load or antenna through an output indicator, apply drive and tune C1, C2, C3, C4, in that order for maximum rf output. These adjustments will interact; therefore, the procedure should be repeated several times until no further increase in output can be obtained.

Several units constructed all produced 15 plus Watts out and provided that little extra power needed when you decide to throw the TR22 on the seat next to you and go mobile.

I want to thank Roy WA4DXU for the use of his rig for photography. Mine wasn't painted pretty. ■

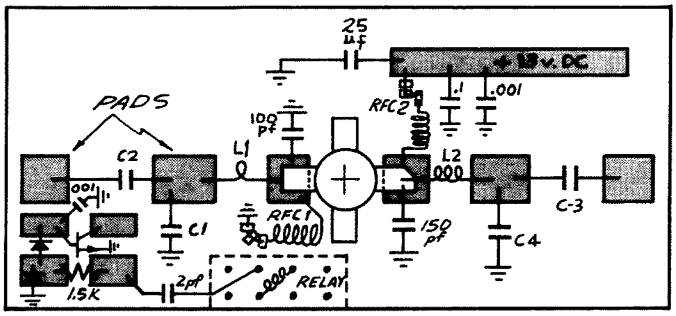

Fig. 2.

Fig. 3. Schematic. Inexpensive HF-VHF Frequency Standard

There have been many frequency standard articles published in recent years using advanced technology integrated circuits[1,2]. However, there is a need for a foolproof circuit that is both inexpensive and easy to build in a modest workshop. While looking for a frequency standard for HF operations I noticed that most authors neglect the need for 30 kHz and 300 kHz markers in VHF FM operations, where 30 kHz is the standard channel spacing. Also, most 2m FM frequency standards neglect the needed 100 kHz and 10 kHz markers as used by the HF man.[2] This is why my interest developed for a simple design frequency standard which could develop both 30 kHz and 10 kHz markers as well as a host of other frequencies.

This standard uses readily available TTL integrated circuits which are available from many sources as advertised in the back of *73 Magazine*. The integrated circuits should not cost more than $4.50 total. The crystal I used was one from my junk box, but an International EX Crystal should work as well, and costs $4.95.

The block diagram of the frequency standard is shown in Fig. 1. Note that a five volt regulator was used to furnish the 5 volts needed by the TTL circuits. By using a regulator, an automobile 12 volt battery can be used to power the frequency standard when tuning up the mobile rig in the car. Also, a lantern battery may be used to power the unit for portable use as on field day. The 9 MHz oscillator is composed of a hex inverter operating in the linear mode. The 9 MHz output from the oscillator is divided by three to generate the 3 MHz signal used by the rest of the circuit. Two divide-by-ten circuits are then used to generate the 300 kHz and 30 kHz marker outputs. When 100 kHz outputs are required, another divide-by-three circuit is inserted between the 3 MHz signal and the divide-by-tens. Since there are two different outputs on each BNC connector, a small LED is used to signal when the second divide-by-three is in the circuit. The LED monitors the output of the divide-by-three, and when it is outputting, the LED is illuminated corresponding to 1 MHz, 100 kHz or 10 kHz selections. When the LED is not illuminated, then the outputs are 3 MHz, 300 kHz or 30 kHz.

The circuit diagram of the frequency standard is shown in Fig. 2. A 7404 TTL hex inverter is used as the crystal oscillator. A small 2-8 pF trimmer capacitor is used to permit zeroing the crystal with WWV. A 7476 TTL dual J-K flip flop is connected in a standard divide-by-three configuration. This same circuit is used later as the divide-by-three in order to produce the 100 kHz markers. A toggle switch selects either the second divide-by-three or bypasses it depending whether 100 kHz markers are needed. Two 7490 TTL decade dividers are then used to furnish the lower frequency markers.

The TTL circuit layout is not critical. The standard, however, should be built close together to keep down stray capacitances. To help those who wish to duplicate the circuit, circuit boards are being made available.[3] Alternatively, the circuit may be built on a small vector board. Sockets may be used to help in the point-to-point wiring.

The board was mounted in a small aluminum box and BNC connectors were used for the outputs. The frequency standard is quite readable at 150 MHz and probably higher. Because of the square wave output, the harmonic content is very high. To calibrate the oscillator, the 100 kHz mode is chosen. The 100 kHz is then compared with WWV at 5, 10 or 15 MHz. The small trimmer capacitor is then adjusted until a zero beat is noted. Using this method, the harmonics at 146 MHz should be no more than a few Hz off. ■

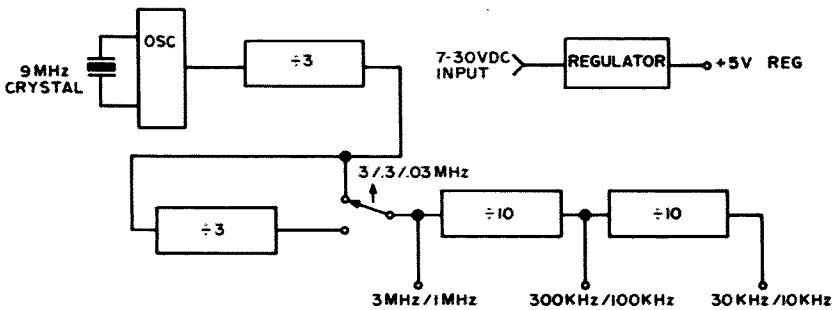

Fig. 1. Block diagram of the frequency standard. Selection of the 1 MHz/.1 MHz/.01 MHz is made by the toggle switch.

Help.

Richard K. Burrows
1335 Faxon Circle
Williamsport PA 17701

Does anyone out there know where I can get a set of schematics for two pieces of equipment I have and can't get running? One is a Motorola Dispatcher, transistorized, model no. D.33BAT-1104A, xmtr. type CC3501, 6 volt.

The tough one came from the MARS program. It's a signal generator that looks like a very good model, but, as with all MARS equipment, it only half works. Though new, it looks like some one has taken the rippers to it and I don't want to get into it unless I have documentation. I'm willing to pay, if need be. It's a SG 47/USM-16, made by B. J. Electronics Div. of Borg Warner, Santa Anna CA. It has modulation, deviation, pulse and rf output 10 to 440 MHz. I have written to the above address but not received an answer. I understand that there are four books for this set, but I couldn't get them from the military. Any help out there?

I/O EDITORIAL

COMPUTERS, SIMPLIFIED

The main part of the I/O section of *73* this month is taken up by a reprint of Nat Wadsworth's explanation of the basics of computers, originally published in the Scelbi-8B User's Manual. It is hoped that this article will dispel once and forever the idea that computers are something mysterious and incredibly difficult to understand.

Computers are complicated, but the basic parts of them are not difficult to get to know, and from there on it is a matter of a whole lot of the same thing over and over, so the complication is one of quantity.

For many ham applications of computers you can think of them as being an almost endless switchboard which can be operated by means of a keyboard rather than individual switches or the soldering of wires. Take a repeater, for instance. Right now repeater nuts have to wire in a time delay for the squelch tale, another for the three minute time out, an ID generator, another timer to play the ID at desired times, an autopatch decoder, and so forth. With a microcomputer, said nut can do all of that with a program. And if he wants to change the length of time for the squelch tale he can go on the air, access the repeater control computer and change it. Ditto the three minute timer . . . perhaps he'd like to shorten the drop out time to two minutes during drive time . . . no strain. The uP will turn on the cassette recorder during autopatches, etc. It is an almost infinitely flexible way of simulating a lot of electronic circuits. Now do you understand what all the fuss is about?

Amateurs have, for the most part, a decided advantage over most of the people who are already into computers. Most of these people are into the programming end of things and it just happens that programming is a lot easier to learn than electronics. We can learn programming quickly, but they will have a long hard row to hoe trying to catch up with us on the digital electronics end.

Well, perhaps you have no great interest in founding a multi-million dollar firm in microcomputers . . . no interest in grabbing a piece of the big computer pie in the sky which is coming. The estimated ham purchases of computers and accessories for this year is only about $50 million . . . let's see now, if we only get 2% of that market that is $1 million in sales. Hmmm. And once a few more people get hold of the Digital Equipment book on computer games the computer hobby market could explode. Fortunately DEC has managed to keep this book a tightly held secret . . . otherwise all hell might break loose. 101 utterly fascinating computer games and the programs to get them running all in one $7.50 book . . . fantastic.

With home use, hobby use, ham use, and business use, computers will be everywhere in a few years. Offices will use the same computer for bookkeeping, invoicing, writing letters (watch out IBM, your $850 Selectric typewriters are about to be made obsolete), inventory, addressing, payroll, indexing, and anything else that now uses paper, pencil, typewriter, etc. Your friendly local computer store will sell, program and service said ubiquitous computers. It is not often that we can see a multi-billion dollar market about to open up and decide whether we want to grab the shirttails or not.

CHU DIGITAL TIME

CHU, the Canadian Observatory station, has added a digital time function to its transmissions. This time tick uses the standard modem tones of 2025 and 2225 Hz and is sent during the 30-39th seconds of each minute. Who will be the first to come up with an article on using this time standard for a ham shack clock or computer application?

The time code is a modified ASCII at 300 baud. During the first 500 ms of each of the 30th to 39th seconds, CHU sends first 10 cycles of 1 kHz (bringing us up to 0.01 seconds . . . 10 ms), then 125 ms of 2225 Hz. This is followed by two bursts of the time code (182.5 ms each). If the two time bursts are not identical the pulses should be ignored.

The time bursts are made up of five 8-bit characters, each containing two decimal numbers (BCD), for a total of ten digits in the pulse. The first digit must be a six as this will prevent inversion of the code. The next three indicate the day of the year, then two for the hour of the day, two for the minute, and two for the second. 2025 Hz is level 1 and 2225 Hz is level 0.

Gearing up to use these digital time clicks is a fine project for you digital home brewers.

SOME PUBLICATIONS OF POSSIBLE INTEREST

by
Wayne Green W2NSD/1
and
Fred R. Goldstein WA1WDS

PCC — People's Computer Company, Box 310, Menlo Park CA 94025. This is a tabloid newspaper bi-monthly . . . $5 for six issues, $9 for two years . . . ran 32 pages in the latest issue. PCC is a mixture of chitchat, news of computers in the schools, game programs, news of products and services . . . emphasis is school computer use. Delightful. PCC has just announced a couple of new publications, TINY BASIC at three issues for $3, a newsletter on Tiny Basic, a new program language for tiny kids so they can write games, do math recreations and operate relays and other real time stuff. The other new publication is a series of booklets on Computers in the Classroom. Book 1, 60 pages Xeroxed, is $3.

Computer Hobbyist, Box 295, Cary NC 27511. $6 a year. This is an advanced type of newsletter and a major source for info from Hal Chamberlin, one of the leading computer hobbyist circuit designers. This is a little heavy for rank beginners . . . a recent issue had a program for generating random numbers and a cassette recorder interface circuit. Editor Stallings is doing a fine job.

Computer Notes, MITS, 6328 Linn Ave NE, Albuquerque NM 87108. While this newsletter is designed primarily for Altair owners, and much of it is far beyond the beginner to comprehend, it is a very well done and interesting publication. Costs $30 per year.

Creative Computing, Box 789, Morristown NJ 07960 . . . $8/yr. Bi-monthly. Heavy on games, complete with programs for them . . . heavy on school use of computers.

Micro-8 Newsletter, Cabrillo Computer Center, 4350 Constellation Road, Lompoc CA 93436. $6/6 issues. Aimed at the hobbyist, particularly the hardware enthusiast and the 8008 user. Tiny type and an enormous amount of info in each issue . . . sources of info, parts, equipment, names and addresses of other hobbyists. Circuits of interest. First rate source.

Microcomputer Dictionary and Guide. Matrix, Champaign IL 61820; $15.95 postpaid. Also available from Radio Bookshop, Peterborough NH 03458.

It's a whopper . . . well over 700 pages . . . and the price is right at $15.95. The term "dictionary" is not quite accurate . . . this is more like what you might expect in an encyclopedia. The definitions of computer terms are not brief; they are almost enough for you to learn about computers just from reading the book.

In a field where there is a completely new lexicon, where it is almost impossible to read articles in computer magazines or newsletters without an interpreter, where you can't even understand the computer folk when you try and talk with them, a dictionary such as this is invaluable.

It is an unfortunate fact that virtually everyone who is deeply involved with computers and has learned the new language also seems to have forgotten English. Computer folk are unable, to a man (it would seem), to write in English or even to talk it. They no longer talk with people, they interface. Without a lot

Computers Are Ridiculously Simple!

Did you just get hooked? Has the first reaction of bewilderment and perplexity set in as you begin to explore the ins and outs of computing? Nat Wadsworth of SCELBI Computer Consulting – makers of an Intel 8008 based packaged microcomputer system – provides us with this article on fundamentals of computer operation. The article is written with the Intel 8008 in mind as an example of a typical computer, but the principles involved apply to nearly any microcomputer you can find on the market. The material of this article is taken from the first chapter of author Wadsworth's SCELBI-8H/B User's Manual, *one of the best documentation support packages among the various kit manufacturers.*

There have been numerous examples put forth over the years to illustrate the basic scheme behind the operation of computers. The scheme is deceptively simple and incredibly powerful. The power comes from the speed with which the machines can perform the simple operations. The fundamental concept of the computer is that it is a machine that is capable of doing two fundamental operations at very high speed: First it is able to obtain a piece of information from a storage area and perform a function as directed by the information it obtains; and secondly, based on its current status, it is able to ascertain where to obtain the next piece of information that will give it further "directions." This fundamental concept is the key to the operation of all digital computers and while it is a simple concept, it can be built upon to arrive at all the complex operations computers of today can perform. How this is done is what this article is about.

One of the best analogies for describing a computer's basic operations is to consider a bank of boxes, similar to a bank of Post Office mail boxes. A piece of paper containing "directions" can be placed in each box. A person is directed to go to the bank of boxes, and after starting at a given place, to open each box, withdraw the piece of paper and follow the directions there-on. The boxes are labeled in an orderly fashion, and the person is also told that unless a piece of paper in a box directs otherwise, when the person is finished performing the task directed, they are to replace the paper in the box and proceed to open the next box. Note, however, that a piece of paper may give directions to alter the sequence in which the person is to open boxes.

Fig. 1 shows a picture of a set of such boxes. Each box is labeled for identification.

To present a view of a computer's operation, assume a person has been told to start at box A1 and to follow the directions contained on the pieces of paper in the boxes until a piece of paper containing the direction "stop" is found in one of the boxes. In this example the person finds the following "instructions":

In box A1 is the message: *"Take the mathematical value of 1 and write it down on a scratch pad."*

Since the "instruction" in box A1 only pertained to some function that the person was to perform, and did not direct the person to go to some specific box, then the person will simply go on to the next box in the row.

Box A2 contains the information:

"Add the number 2 to any value already present on your scratch pad."

The person will at this point perform an addition and have a total "accumulated" value on the pad of scratch paper. The accumulated value would be 3. Since there are no other directions in box A2, the operator would continue on to open box A3 which has the following message:

"Place any accumulated mathematical value you have on your scratch pad into box H8."

Thus the person would tear the current sheet off the "scratch pad" and place it – containing the value "3" – into box H8. Note, though, that while the person was directed to place the accumulated value on the scratch pad into box H8, the person was not directed to alter the sequence in which to obtain new "instructions" so the person would proceed to open box A4 which contains the directive:

"Take the mathematical value of 6 and place it on your scratch pad."

Going on to box A5 the person finds:

"Add 3 to the present value on your scratch pad."

This is obviously just a "data word." The operator adds the value 6 from the previous box to the number 3, noting the calculation on the scratch pad and proceeds to open box A6:

"Place any accumulated value you have on your scratch pad into box H7."

The person thus would put the value "9" on a piece of paper (from the scratch pad) into the designated box and proceed to open box A7:

"Get the value presently stored in box H8 and save the value on your scratch pad."

This is a simple operation and the person proceeds to open up box A8:

"Fetch the value in box H7. Subtract the value of your scratch pad from the value found in box H7. Leave the result on your scratch pad."

When the operator has performed this operation, the operator will have finished the "A" row and will then continue obtaining "instructions" by going to the "B" row and opening box B1 where more directions are found:

"If the present value on your scratch pad is not zero go to box B3."

At this time if the person checks the scratch pad it will be found that the value on the scratch pad is indeed non-zero as the last calculation performed on the scratch pad was to subtract the value in box H8 from the value in box H7. In this example that would be:

$$9 - 3 = 6$$

Therefore the directions in box B1 for this particular case will tell the operator to "jump over" box B2 and go to box B3. For the sake of completeness, however, box B2 does contain an instruction, for had the value on the scratch pad been zero the operator would not have "jumped over" box B2 and would have found the following message inside box B2:

"The values in box H7 and H8 are of equal value. STOP!"

However, for the values used in this example, the person would have "jumped" to box B3 where the following directive would be found:

"If the present value on your scratch pad is a "negative number" jump to box B5."

Since this is not currently the case the person will not "JUMP" to box B5, but will simply continue to open box B4 which contains:

"The value in box H7 is larger than the value in box H8. STOP!"

At this point the person has completed the "instruction sequence" for this example. It should be noted, however, that box B5 did contain the message:

"The value in box H7 is smaller than the value in box H8. STOP!"

This little example of a person opening up boxes and following the directions

The basic scheme behind the operation of computers is deceptively simple and incredibly powerful.

contained in each one is very similar to the concept used by a computer. Note that each "instruction" is very short and specific. Also note that the combination of all the instructions in the example will result in the person being directed to solve the problem:

Is 1 + X greater than, less than, or equal to: 6 + Y?

For the reader can note, if the "data words" contained in boxes A2 and A5 for the example were changed, the sequence of "instructions" would still result in the person being told to "STOP" at the box that contained the correct answer. The reader can verify this by simply assuming that different numbers than those used in the example are in boxes A2 and A5 and going through the instruction sequence until told to "STOP."

The example illustrates how a carefully planned set of directions, arranged such that they are performed in a precise sequence, can be used to solve a problem even though the "variables" (data) in the problem may vary. Such a set of "instructions" is often termed an "algorithm" by those in the computer field. The example solved a mathematical problem using the "algorithm," but the reader will find that "algorithms" can be devised to solve many problems on a computer that are not strictly mathematical!

Any person learning a new skill must of necessity learn the vocabulary of the field in order to proceed to any great extent. You might think that it would be easier if everything was written in plain everyday words, but the truth of the matter is that specialized vocabularies do serve several useful functions. For one thing, they can greatly shorten the time that it takes to communicate ideas or concepts. In today's fast-moving world, that is of significance in itself. In addition, the limitations of the English language often result in a given word having a special meaning when it is used in the context of a particular subject. One must know the new meaning when it is used in such a manner. Fortunately, much of the computer vocabulary is very logically named. This is probably due partly to the fact that computers are of necessity extremely dependent on logic, and hence many persons who helped create the field – and by that fact were rather logically oriented themselves – seem to have had the logical sense to have named many of the parts and systems of computers and computer programs, in a logical manner.

In the text which follows, two diagrams, Figs. 2(a) and 2(b), are used to demonstrate the analogy between the person taking "instructions" from a group of mail boxes and the basic operation of a real minicomputer.

Fig. 2(a) shows the Post Office boxes, a figure representation of a person who is able to "fetch" and return the "instructions" or "data" from and to the boxes, and a "scratch pad" on which the person can make temporary calculations when directed to do so.

In Fig. 2(b) are three interconnected boxes which form a "block diagram" of a computer. The uppermost portion of the "block diagram" is labeled the "memory." The middle portion is labeled the "central processor unit" or "CPU" for short. The lower part of the diagram depicts an "accumulator."

The correlation between the two pictures is extremely simple. The "Post Office boxes" correspond to the "memory" portion of a real computer. The "memory" is a storage place, a location where instructions and data can be stored for long lengths of time. The "memory" can be "accessed." "Instructions" and/or "data" can be taken out of memory, operated on, and replaced. New "data" can be put into the "memory." A "memory" that can be "read from" as well as "written into" is called a "read and write memory." A "read and write memory" is often referred to as a "RAM" as an abbreviation. Many times it is feasible to have a "memory" that is only "read from." A memory that is never "written into," but is only used to "read from," is termed a "read only memory" and is abbreviated as a "ROM." For the present discussion the term "memory" will refer to a "read and write memory" ("RAM").

The figure of a person in Fig. 2(a) corresponds to the central processor unit in Fig. 2(b). The cental processor

unit in a computer is the section that "controls" the overall operation of the machine. The "CPU" can receive (fetch) "instructions" or "data" from the memory. It is able to "interpret" the "instructions" it fetches from the memory. It is also able to perform various types of mathematical operations. It can also "return" information to the memory – for instance make deposits of "data" into the memory. The "CPU" also contains control sections that enable it to sequentially "access" the "next" location in memory when it has finished performing an operation, or, if it is directed to do so, to "access" the memory at a specified location, or to "jump" to a new area in memory from which to continue fetching "instructions."

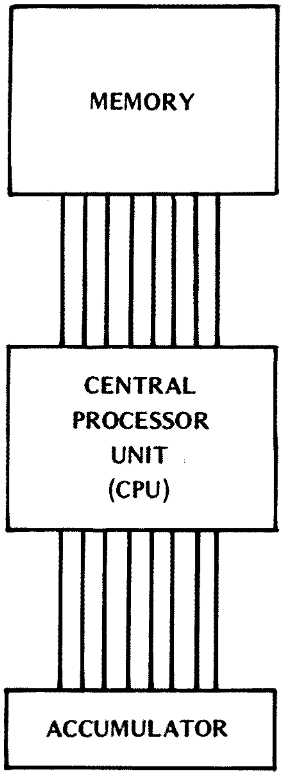
The pad of paper and pencil in Fig. 2(a) corresponds to the block titled "accumulator" in Fig. 2(b). The "accumulator" is a temporary "register" or "manipulating area" which is used by the CPU when it is performing operations such as adding two numbers. One number or piece of information can be temporarily held in it while the central processor unit goes on to obtain additional instructions or data from memory. It is an electronic "scratch pad" for the CPU.

The three fundamental units – the memory, central processor unit, and the accumulator – are at the heart of every digital computer system. Of course, there are other parts which will be added in and explained later, but these fundamental portions can be used to explain the basic operation of a digital computer which is the purpose of this article.

The reader should learn the names of the basic parts of the computer as they are presented. Note how easy it is to remember the portions that have been shown. The "remembering" element is a "memory." The portion that does the "work" or processing is simply termed the "central processor unit," and the part that is used to accumulate information temporarily is aptly called the "accumulator!"

The reader should now have a conceptual view of the concept behind a computer's operation and an understanding of the machine's most basic organization. It is simply a machine that can fetch information from a memory, interpret the information as an instruction or data, perform a very small operation, and continue on to determine the next operation that is to be performed. Each operation it is capable of doing is very tiny by itself, but when the many operations of a typical "program" are performed in sequence, the solutions to very complex problems can be obtained. It is important to remember that the computer can perform each little operation in just a few millionths of a second! Thus a program that might seem very large to a person – say one with many thousands of individual instructions – would only take a digital computer a few thousandths of a second to perform. The speed with which the computer can execute individual instructions is what gives the computer its seemingly fantastic capability.

Fig. 2(b). Block diagram of a computer's fundamental components.



It is now time to start delving into the actual physical manner in which a computer operates. How can a machine be constructed so that it is able to perform the processes of the central processor unit? While it will require a number of pages of text to explain the procedure, it is not nearly as difficult to understand as many people might suspect. The complexity of a computer when first viewed by a person is caused by the fact that it appears to consist of many hundreds of parts. It becomes much simpler when one understands that the hundreds of parts are really made up from a few dozen similar parts and they are carefully organized into just a few major operating portions. The reader is already familiar with the most fundamental portions.

As fantastic as it may sound at first, a digital computer can be thought of as really nothing more than a highly organized collection of "on or off" switches! Yes, computers are constructed from electronic devices that can only assume one of two possible states! The electronic switches can be constructed in a variety of ways. For instance, the switch can be made so that the voltage at a given point is either high or low, or current through a device is either flowing or not flowing, or flowing in one direction, and then the other direction. But, regardless of how the electronic switch is constructed, its status can always be represented as being either "on" or "off." This "on" or "off" status can be mathematically symbolized most suitably by a mathematical system based on "binary" notation.

Some people tend to think that computers are very difficult to understand because they have heard of "strange" types of mathematics that are often

As fantastic as it may sound at first, a digital computer can be thought of as really nothing more than a highly organized collection of "on or off" switches!

referred to in conjunction with computers. In actuality much of the mathematics that are dealt with in computer technology are much easier to understand and deal with than the decimal system that the average person is familiar with. In the decimal numbering system a person must learn 10 different symbols, and in order to manipulate those symbols, they must memorize a lot of information. For instance, look at how students are taught to multiply. The learning process actually involves the student having to memorize a rather large number of facts. Because of the way it is typically taught, most students never realize how much work they have to go through just to learn the multiplication tables! The teacher does not stand up and say, "OK, now you are going to memorize about 100 facts." Instead, over a period of a few weeks or so, the student is made to memorize the 100 or so facts – a few at a time. The student must learn the value of each digit multiplied by all the other digits in the decimal numbering system. The decimal numbering system is far more complicated for the beginner than learning the binary numbering system, and the binary numbering system is the one utilized by computers at their most basic functioning level. The reason the computer uses the binary system is because it is the simplest system around and hence the easiest one with which to construct a computing machine!

Readers know the word "binary" indicates "two." Computers are built up of electronic switches that can only have two possible states. The switches are binary devices. The status of the switches can be represented mathematically utilizing the "binary" numbering system. The binary numbering system only has two digits in it! They are zero (0) and one (1). A switch can thus be mathematically symbolized, for instance, by a zero when it is "off" and a one when it is "on." The opposite relationship could also be established, a one could be used to represent a switch being "off" and a zero used to represent a switch as "on." It would make no difference mathematically which convention was used as long as one was consistent. For the purposes of the present discussion, the reader can assume that the first convention (switch off = 0, switch on = 1) will be used.

It should be immediately apparent that working with a numbering system based on only two integers will be a lot easier than working with one having 10 integer symbols. In fact, most problems for people learning the binary system come about because they tend to forget how simple it is, and they tend to keep going towards a decimal solution out of habit when they are working with the binary system. For instance, when one starts to add binary numbers, as soon as the value "1" is exceeded, a "carry" to the next column must be made. The value of the addition of "1 + 1" in the binary system is: 10. It is not 2! There is no such integer as "2" in the binary numbering system. However, when a person who has worked with the decimal system for years first starts working with the binary system, old decimal habits tend to get in the way. The reader will have to beware!

To formally introduce the binary mathematical system one can start by stating that it uses two integers, zero (0) and one (1), and no others. A binary number has a value determined by the value of the integers that make up the number, and the position of the digits.

In the decimal numbering system, the reader is familiar with the location of a digit having a "weighted" value as follows: A three digit number has a value determined by the unit value of the digit in the right-most column plus the value of the digit to the left of it multiplied by 10, plus the value of the third digit multiplied by one hundred as illustrated in the following example:

THE DECIMAL NUMBER
345 IS EQUAL TO:

5 UNITS = 5
PLUS(+) 4 TIMES 10 = 40
PLUS (+) 3 TIMES 100 = 300

In other words, after the right-most column (which has the value of the digit), each column to the left is given a weighting factor which increases as a power of the total number of digits utilized by the numbering system. Note that in the above example the 4 representing 40 units is equal to 4 times the number of integer symbols in the decimal system (10) because it is located in the second column from the right. The number 3 representing 300 units is equal to 3 times the number of integer symbols in the decimal system squared because it is located in the third column from the right. This relationship of the weighted value of the digits based on their position can be described in mathematical shorthand as follows:

If the number of different integer symbols in the numbering system is U (for the decimal system U=10)

and the column whose weighted value is to be determined is column number M (starting with the right-most column and counting to the left)

and any digit is represented by the symbol X

then the weighted value of a digit in column M is expressed as:

X times U raised to the power (M-1) or $XU^{(M-1)}$

The reader can easily verify that the above formula applies to the decimal numbering system. However, the above formula is a general formula that can be used to determine the weighted positional value of any numbering system. It will be used to determine the weighted positional values of numbers in the binary numbering system.

In the binary numbering system there are just two different integer symbols (0

and 1). Thus U in the above formula is equal to 2. For illustrative purposes assume the following binary number is to be analyzed:

1 0 1

and it is desired to determine its value in terms of decimal numbers. (Remember its binary value is just 1 0 1). Using the above formula for the digit in the right-most column: M is equal to 1, thus (M-1) is equal to 0, and with X = 1:

$$\text{Weighted Value} = X \cdot U^{(M-1)} = 1 \cdot 2^{0} = 1$$

(Remember that any number raised to the zero power is equal to 1.) Going on to the next digit it can be seen that the weighted value is simply 0! Finally, the digit in the third column from the right has the weighted value because of its position:

$$\text{Weighted Value} = X \cdot U^{(M-1)} = 1 \cdot 2^{(3-1)} = 2^{2} = 4$$

Then, by adding up the sum of the weighted values (similar to that done for the decimal example earlier) one can see that the decimal equivalent of 1 0 1 binary is 5:

THE BINARY NUMBER 101

IS EQUAL TO:

	1 UNITS	=	1
+	0 TIMES 2	=	0
+	1 TIMES 4	=	4

and thus 1 0 1 in the binary numbering system is the same as 5 in the decimal numbering system.

There will be more to learn about the binary numbering system. However, the brief information given will be enough to continue on with the discussion that this section is primarily concerned with – the basic operation of a computer. Since the reader is now aware that a computer is composed of numerous electronic switches and knows that one can use a mathematical shorthand to represent the status of the switches (whether they are "on" or "off"), and is also aware of the fundamental concept behind a computer's operation, it is now possible to proceed to show how electronic switches can be arranged to build a functional computer. That is, how the electronic switches can be arranged and interconnected in a fashion that will allow a machine to "fetch" a piece of information from a "memory" section, decode the information so as to determine an "instruction," and also determine where to obtain the next instruction or additional "data."

To begin this part of the discussion it will be beneficial for the reader to picture a group of cells (similar to the Post Office boxes shown earlier) arranged in orderly rows as shown in Fig. 3. This time, instead of each cell holding a complete instruction, it can be understood that each cell only represents part of an instruction and that it takes a whole row of cells to make up an instruction. Furthermore, each cell may only contain the mathematical symbol for a one (1) or a zero (0) – or, in other words, its contents represent the status of an electronic switch!

At this time a few more computer technology definitions will be illustrated. In Fig. 3, each box containing a binary 1 or 0 represents what is called a "bit" of information. While each cell may only contain one piece of information at a time, a cell can actually represent one of two possible states of information. This is because the cell can be in two possible states – it either contains a zero or a one. If one starts assigning positional values to the cells in a row, it can be seen that the total number of possible states in one row will increase rapidly. For instance, two cells in a row can represent up to four states of information. This is because two cells side-by-side, containing either a 0 or 1 in each cell can have one of the following four states at a particular moment in time: 1

The decimal numbering system is far more complicated for the beginner than learning the binary numbering system, and the binary numbering system is the one utilized by computers at their most basic functioning level.

WORD #1	1	0	1	0	1	0	1	0
WORD #2	0	1	0	1	0	1	0	1
WORD #3	1	1	0	0	1	1	0	0
WORD #4	0	0	1	1	0	0	1	1
WORD #5	1	1	1	1	0	0	0	0
WORD #6	0	0	0	0	1	1	1	1
WORD #7	1	1	1	1	1	1	1	1
WORD #8	0	0	0	0	0	0	0	0

Fig. 3. An array of electronic cells, 8 bits per cell.

The combination of the eight cells can be filled with zeros and ones in 256 different patterns.

0, 0 1, 1 1, or 0 0. Three cells in a row can represent up to eight states of information as the possible states of three cells side-by-side are: 0 0 0, 0 0 1, 0 1 0, 0 1 1, 1 0 0, 1 0 1, 1 1 0, 1 1 1. In fact, when each cell can represent a binary number, the total number of states of information that a row of "N" cells can represent is: 2 to the Nth power, 2^n. Thus, a row of eight binary cells can represent 2 to the eighth (256) states of information! That is, the combination of the eight cells can be filled with zeros and ones in 256 different patterns!

A group (row) of cells in a computer's memory is often referred to as a "word." A "word" in a computer's memory is a fixed size group of cells that are "accessed" or manipulated during one operational cycle of the central processing unit (CPU). The CPU will effectively handle all the cells in a "word" in memory simultaneously whenever it processes information in the memory. Digital computers can have varying "word lengths" depending on how they are engineered. Many microcomputers have a memory word size consisting of eight cells. The number of cells in a word, and the number of words in a computer's memory have a lot to do with the machine's overall capability. In the typical microcomputer system, the memory is available in modules – groups of words which can be plugged into a common set of wires in the system. With current LSI technology, a typical module of moderate price has 1024 bytes in an 8-bit computer system. With the 8008 oriented design serving as the basis for this article, one could potentially plug in 16 such modules for a total of 16,384 bytes or 131,072 bits. Thus, a large amount of information can be "stored" in the computer's memory at any one time.

The astute reader may have already figured out a very special reason for grouping cells into "words" in memory. It was pointed out earlier that a row of eight cells could represent up to 256 different patterns. Now, if each possible pattern could be "decoded" by electronic means so that a particular pattern could specify a precise "instruction" for the central processor unit, then a large group of "instructions" would be available for use by the machine. That is exactly the concept used in a digital computer. Patterns of ones and zeros organized into a computer "word" are stored in memory. The CPU is able to examine a word in memory and decode the pattern contained therein to determine the precise operation that it is to perform. Most microcomputers do not decode every one of the possible 256 patterns that can be held in a row of eight cells as an instruction. They have an "instruction set" of over 100 "instructions" which are represented by different patterns of ones and zeros in an eight cell memory "word." Each pattern that represents an "instruction" can be decoded by the CPU and will cause the CPU to perform a specific function. Details of all the functions a computer can perform are usually found in the manufacturer's documentation.

There is another ingredient necessary for making the machine "automatic" in operation. That is that the CPU must "know" where to obtain the next "instruction" in memory after it completes an operation. That function is greatly aided by having the memory cells grouped as "words." The reader should note that in Fig. 3 each group of cells representing a word was labeled as: "word #1," "word #2," etc. There is a special portion of the central processor unit that is used to control where the next word containing an instruction in memory is located. This special part is commonly referred to as the "program counter." One reason it was given the name "program counter" is because most of the time all it does is count! It counts memory words! Each word in memory is considered to have an "address." In Fig. 3 each word was given an "address" by simply designating each word with a number. Word #1 has an "address" of 1. Word #2 has an address of 2, etc. The "program counter" portion of the CPU keeps tabs on where the CPU should obtain the next instruction by maintaining an "address" of the word in memory that is to be processed! About 90% of the time all the program counter does is "increment" the value it has each time the CPU finishes doing an operation. Thus, if the computer were to start executing a simple program that began by its performing the instruction contained in "word #1" in memory – the very process of having the machine start the program at that location in memory would cause the program counter to assume a value of 1. As soon as the CPU had performed the function the "program counter" would increment its value to 2. The CPU would then look at the program counter and see that its next instruction was located in word #2 in memory. When the instruction in word #2 has been processed the "program counter" would increment its value to 3. This process might continue uninterrupted until the CPU found an instruction that told it to "STOP."

A sharp reader might be starting to ask, "Why have a program counter if each instruction follows the next?" The answer is simply that the availability of a "program counter" gives the freedom of not having to always take the instruction at the next "address" in memory. This is because the contents of the "program counter" can be changed when the CPU detects an "instruction" that directs it to do so! This enables the computer to be able to "jump" around to different sections in memory, and as will become apparent later, greatly increases the capability of the machine.

Fig. 4. The program counter of an 8008 based machine.

13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	0

The "program counter" is actually just a group of cells in the CPU that may contain either a binary zero or one. The binary value in the row of cells that constitute the program counter determines the "address" of a word in memory. Since the number of words in memory can be very large, and since the program counter must be capable of holding the address of any possible location in memory, the number of cells in a row in the program counter is larger than the number of cells in a word in memory. In an 8008 oriented computer design, for example, the number of cells in the program counter is 14. Since 2 to the 14th power is 16,384, the program counter can present up to 16,384 different patterns. Each pattern can be used to represent the "address" of a word in memory. Fig. 4 illustrates what the contents of the program counter would look like when it contained the address for a specific word in memory. The address the example displays is "address 0" which can be considered the first word in memory. The reader should note that an address of zero can actually represent a word in memory!

Earlier it was stated that some "instructions" can actually change the value of the program counter and thus allow a program to "jump" to different sections in memory. However, the reader now knows that a word in memory only contains eight cells, and yet the program counter of an 8008 based computer contains 14 cells. In order to change the entire contents of the program counter (by bringing in words from memory), it is necessary to use more than one memory word! This can be done if the program counter is considered to actually be two groups of cells connected together. One group contains eight cells, and the other six. In order to change the contents of the entire program counter, one whole eight cell word could be read from a memory location and placed in the right-hand group of eight cells of the program counter. Then another eight cell word could be read from memory. Since only six more cells are needed to finish filling the program counter, the information in two of the eight cells from the second word brought in from memory could be "discarded." If the information in the two left most cells of the word in memory were thrown away then the remaining six cells would contain information that could be placed in the six unfilled locations in the program counter. Most of the common 8-bit micro-computers use a similar scheme of breaking an address into two pieces when the program counter is loaded in a jump instruction.

In order to make it easier for a person working with the machine to remember "addresses" of words in memory, a concept referred to by computer technologists as "paging" is utilized. "Paging" is the arbitrary assignment of "blocks" of memory words into sections that are referred to figuratively as "pages." The reader should realize that the actual physical memory unit consists of all the words in memory – with each word assigned a numerical address that the machine utilizes. As far as the machine is concerned, the words in memory are assigned consecutive addresses from word #0 on up to the highest word # contained in the memory. However, people using computers have found it easier to work with addresses by arbitrarily grouping "blocks" of words into pages. For example in the Intel 8008 "pages" are considered to be "blocks" of 256 memory words. The first memory word address in an 8008 system is at address zero (0). Programmers could refer to this word as word #0 on page #0. The 256th word in memory as far as the computer is concerned has an address of 255. (Note: Since the address of 0 is actually assigned for the first physical word in memory, all succeeding words have an address that is one less than the physical quantity!) A programmer could refer to this word as word #255 on page #0. The 257th word in memory has an absolute address of 256 ("n"th word minus one since location 0 contains a memory word) as far as the machine is concerned, but a programmer could refer to that word location as being on page #1 at location 0! Similarly, the 513th word in memory, when the paging concept is used, becomes word #0 on page #2 for a programmer – but it is just 512 as far as the machine is concerned. Paging at multiples of 256 is a convenient tool when dealing with any 8-bit micro-computer.

The reader might have noted a nice coincidence in regards to the assignment of "paging" in 8-bit computers. Each "page" refers to a

There is a special portion of the central processor unit (CPU) that is used to control where the next word containing an instruction in memory is located – the "program counter." Most of the time all it does is count!

"block" of memory words that contains 256 locations (0 to 255). The reader will recall that that is exactly the number of different patterns that can be specified by a group of eight binary cells, and there are eight binary cells in a memory "word." The relationship is more than coincidental! Note that now one has devised a convenient way for a person to be able to think of memory addresses and at the same time be able to specify a new address to the program counter that will still result in it containing an "absolute" address that the machine can use. For instance, if it was desired to change the contents of the 14 cell program counter from an absolute address of word #0, say to word #511, the following procedure could be used: The programmer would first specify an instruction that the CPU would decode as meaning "change the value in the program counter." (Such an instruction might be a "jump" instruction in the instruction set.) Following that instruction would be a word that held the desired value of the "low order address" or word # within a "page." Since a memory word only has eight cells, since eight cells can only represent 256 different patterns, and since one of the patterns is equivalent to a value of zero, then the largest number the eight cells can represent is 255. However, this is the largest word # that is contained on a page. This value can be placed in the right-most eight cells of the program counter. Now it is necessary to complete the address by getting the contents of another word from memory. Thus, immediately following the word that contained the "low address" would be another word that contained the "page #" of the address that the program counter was to contain. In this case the page number would be 1. When this value is placed in the left six cells of the program counter the program counter would contain the pattern in Fig. 5.

If desired, the reader can verify by using the formula presented previously for determining the decimal value of a binary number, that the pattern presented in Fig. 5 corresponds to 511, and thus, by using the "page #" and "word # on the page," each of which will fit in an eight cell memory word, a method has been demonstrated that will result in the program counter being set to an absolute address for a word in memory. Fig. 6 provides some examples as a summary.

By now the reader should have a pretty good understanding of the concepts regarding the organization of memory into electrical cells which can be in one of two possible states, the grouping of these cells into "words" which can hold patterns which the CPU can recognize as specifying particular operations, and the operation of a "program counter" which is able to hold the "address" of a word in memory from which the CPU is to obtain an instruction.

It is now time to discuss the operation of the "scratch pad" area for a computer – the accumulator (and some

Fig. 6. Examples of addresses in an 8008 based system.

additional "manipulating registers" in the typical 8008 based computer).

As was pointed out earlier, there is a section of a computer that is used to perform calculations in and which can hold information while the CPU is in the process of "fetching" another instruction from the memory. The portion was termed an "accumulator" because it could "accumulate" information obtained from the CPU performing a series of instructions until such time as the CPU was directed to transfer the information elsewhere (or discard it). The accumulator is also considered to be the primary "mathematical" center for computer operations for it is the place where additions, subtractions, and various other mathematically oriented operations (such as Boolean algebra) are generally performed under program control.

The concept of an "accumulator" is not difficult to understand and its physical structure can be readily explained. The actual control of an accumulator by the CPU can be quite complex, but these complex electronic manipulations do not have to be understood by the computer user. It is only necessary to know the "end results" of the various operations that can be performed within an accumulator.

The accumulator in an Intel 8008 based machine can be considered as a group of eight "memory cells" similar to a "word" in memory except that the information in the cells can be manipulated in many ways that are not directly possible in a word in memory.

Fig. 7 shows a collection of eight binary cells containing ones and zeros to represent an accumulator. The cells are numbered from left to right starting with "B7" down to "B0." The designations refer to "bit positions" within the accumulator. Note that the right-most cell is designated B0 and the eighth cell (left-most cell) is designated B7. The reader should become thoroughly familiar with the concept of assigning the reference of "zero" to the right-most bit position in a row of cells (similar to the concept of assigning a reference of zero to the first address of a word on a page in memory) as the convention is frequently used by computer technologists. The convention can be confusing for the beginner who fails to remember that the physical quantity is one more than the reference designation. The convention of labeling the first physical position as zero makes much more sense once the reader learns to think in terms of the binary numbering system and thoroughly realizes that the "zero" referred to so frequently in computer work when discussing actual operations actually represents a physical state (the status of an electronic switch) and does not necessarily imply the mathematical notion of "nothing." The concept of assigning a bit designation to the positions of the cells within the accumulator will allow the reader to follow explanations of various accumulator operations.

Fig. 7. The accumulator, pictured with binary 10101010 (decimal value 160) in its 8 bits.

1	0	1	0	1	0	1	0

The accumulator simply holds a number–it adds and subtracts–and "rotates" its contents.

One of the most fundamental and most often used operations of an accumulator is for it to simply hold a number while the CPU obtains a second operator. In an 8008 type of machine the accumulator can be "loaded" with a value obtained from a location in memory or one of the "partial accumulators." It can then hold this value until it is time to perform some other operation with the accumulator. (It will become apparent later that the accumulator of an 8008 can also receive information from external devices.)

Perhaps the second most often used operation of an accumulator is to have it perform mathematical operations such as addition or subtraction with the value it contains at the time the function is performed and the contents of a memory location or one of the "partial accumulators." Thus if the accumulator contained

the binary equivalent of the decimal number 5, and an instruction to add the contents of a specific memory location which contained the binary equivalent of the decimal number 3 was encountered, the accumulator would end up with the value of 8 in binary form as shown in Fig. 8.

Perhaps the next most frequently used group of operations for the accumulator is for it to perform "Boolean" mathematical operations between itself and/or other "partial accumulators" or words in memory. These operations in the typical microcomputer include the logical "and," "or," and "exclusive or" operations.

Another important capability of the accumulator is its ability to "rotate" its contents. In an 8008, as in many micros, the contents of the accumulator can be rotated either to the right or left. This capability has many useful functions, and is one method by which mathematical multiplication or division can be performed. Fig. 9 illustrates the concept of "rotating" the contents of the accumulator.

The astute reader may notice that the accumulator rotate capability also enables the accumulator to emulate a "shift register" which can be a valuable function in many practical applications of the computer.

The accumulator serves another extremely powerful function. When certain operations are performed with the accumulator the computer is capable of examining the results and will then "set" or "clear" a special group of "flags." Other instructions can then test the status of the special "flags" and perform operations based on the particular setting(s) of the "flags." In this manner the machine is capable of "modifying" its behavior when it performs operations depending on the results it obtains at the time the operation is performed!

In an 8008 based computer, there are four special flags which are manipulated by the results of operations with the accumulator (and in several special cases by operations with "partial accumulators"). These four flags are described in detail below. Other micros have similar condition flags.

The "carry flag" can be considered as a one bit (cell) extension of the accumulator register. This flag is changed if the contents of the accumulator should "overflow" during an addition operation (or "underflow" during a subtraction operation). Also, the "carry bit" can be utilized as an extension of the accumulator for certain types of "rotate" commands.

The "sign flag" is set to a logic state of "1" when the most significant bit (MSB) of the accumulator (or partial accumulator) is a "1" after certain types of instructions have been performed. The name of this flag derives from the concept of using two's complement arithmetic in a register where the MSB is used to designate the sign of the number in the remaining bit positions of the register – conventionally, a "1" in the MSB designates the number as a "negative" number. If the MSB of the accumulator (or partial accumulator) is "0" after certain operations, then the "sign flag" is zero (indicating that the number in the register is a positive number by two's complement convention).

The "zero flag" is set to a logic state of "1" if all the bits in the accumulator (or partial accumulator) are set to zero after certain types of operations have been executed. It is set to "0" if any one of the bits is a logic one after these same operations. Thus the "zero flag" can be utilized to determine when the value in a particular register is zero.

The "parity flag" is set to a "1" after certain types of operations with the accumulator (or partial accumulators) when the number of bits in the register that are a logic one is an even value (without regard to the positions of the bits). The "parity flag" is set to "0" after these same operations if the number of bits in the register that are a logic one is an odd value (1, 3, 5 or 7). The "parity flag" can be especially valuable when data from external devices is being received by the computer to test for certain types of "transmission errors" on the information being received.

In its simplest form, a group of switches can be used as an input device and a group of lamps as an output device!

In addition to the full accumulator previously discussed there are six other 8 bit registers in the Intel 8008 computer referred to as "partial accumulators" because they are capable of performing two special functions normally associated with an accumulator (in addition to simply serving as temporary storage registers). The full accumulator will often be abbreviated in this manual as "ACC" or "register A." The six "partial accumulators" will be referred to as "registers B, C, D, E, H and L."

Registers B, C, D, E, H and L of an 8008 are all capable, upon being directed to do so by a specific instruction, of either incrementing or decrementing their contents by one. This capability allows them to be used as "counters" and "pointers" which are often of tremendous value in computer programs. What makes them especially valuable in 8008 architecture is that when their contents are incremented or decremented the immediate results of that register will affect the status of the "zero," "sign," and "parity" flags discussed above. Thus it is possible for the particular contents of these registers to affect the operation of the computer during the course of a programs operation and they can be used to "guide" or modify a sequence of operations based on conditions found at the actual time a program is executed.

Fig. 9. Rotating the content of the accumulator.

B7	B6	B5	B4	B3	B2	B1	B0	
0	0	0	0	0	0	1	0	ORIGINAL CONTENTS OF THE ACCUMULATOR (EQUAL TO DECIMAL 2)
0	0	0	0	0	1	0	0	RESULT WHEN THE ACCUMULATOR IS ROTATED TO THE LEFT ONE TIME (VALUE NOW EQUAL 4)
0	0	0	0	0	0	0	1	RESULT WHEN THE ACCUMULATOR IS NOW ROTATED TO THE RIGHT TWO TIMES (VALUE NOW EQUAL 1)
1	0	0	0	0	0	0	0	NOTE THAT IF A ROTATE RIGHT COMMAND IS DONE AGAIN THAT THE "1" IN POSITION B 0 WILL APPEAR AT B 7 !!
0	0	0	0	0	0	0	1	AND THAT NOW A ROTATE LEFT COMMAND WOULD RESTORE THE "1" IN POSITION B 7 BACK TO B 0 !

It should be noted that registers B, C, D, E, H and L are capable of being incremented and decremented — but the full accumulator — register A — cannot perform those two functions in the same manner. (The full accumulator can be incremented or decremented by any value by simply adding or subtracting the desired value. There is not, however, a simple increment or decrement by one instruction for use with the full accumulator of an 8008!)

Two of the partial accumulators, registers H and L, serve an additional purpose in the 8008 computer CPU. These two registers can be used to directly "point" to a specific word in memory so that the computer may obtain or deposit information in a different part of memory than that in which a program is actually being executed. The reader should recall that a special part of the central processor unit (CPU) termed the program counter is used to tell the computer where to obtain the next instruction while executing a program. The program counter was effectively a "double word length" register that could hold the value of any possible address in memory. The program counter is always used to tell the machine where to obtain the next instruction. However, it is often desirable to have the machine obtain some information — such as a "data word" — from a location in memory that is not connected with where the next instruction to be performed is located. This can be accomplished by simply loading "register H" with the "high address" (page) portion of an address in memory, then loading "register L" with the "low address" portion of an address in memory, and then utilizing one of a class of commands that will direct the CPU to fetch information from or deposit information into the location in memory that is specified ("pointed to") by the "H" and "L" register contents. This information flow can be from/to the location specified in memory and any of the CPU registers.

At this time it would be beneficial for the reader to study Fig. 10. Fig. 10 is an expanded block diagram of Fig. 2(b) and shows the units of the computer which have been presented in the previous several pages.

Until now no mention has

It has been said that the computer is the most versatile machine in existence and that its applications are limited only by man's ability to develop programs that direct the operation of the machine.

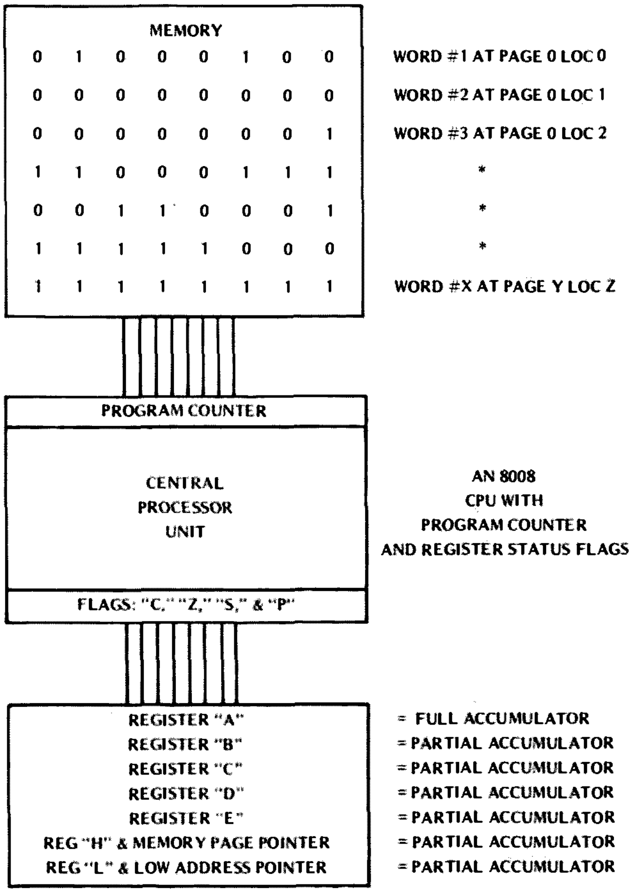
The computer's great versatility comes about because the machine is capable of executing a large group of instructions in an essentially limitless series of combinations.

been made of how information is put into or received from a computer. Naturally, this is a very vital part of a computer because the machine would be rather useless if people could not put information into the machine upon which calculations or processing could be done, and receive information back from the machine when the operations(s) had been performed!

Communications between the computer and external devices – whether those devices be simple switches, or transducers, or teletype machines, or cathode-ray-tube display units, or keyboards, or "mag-tape" and "disk" systems – or whatever, are commonly referred to as input/output operations and are collectively referred to in abbreviated form as "I/O" transfers.

In the Intel 8008 computer designs all "I/O" transfers are typically made between external "I/O ports" (which connect to external devices via appropriate electronic connections) and the full accumulator in the computer. This I/O structure means that a whole group of devices can be simultaneously hooked up to the computer and the computer used to receive information from or transmit information to a variety of devices as directed by a "program." A special set of commands is used to instruct the computer as to which "I/O port" is to be operated at any particular instant. With appropriate programming it is then possible to have the computer "communicate" with a large variety of devices in an essentially "automatic" mode – for instance receiving information from a digital multimeter at specified times, then possibly performing some averaging calculations, and then outputting results to a teletype machine without human intervention. Or, in other applications – information from a human operator can be typed into the machine using a typewriter-like keyboard. In its simplest form, a group of switches can be used as an input device and a group of lamps used as an output device for the computer!

Fig. 10. The block diagram of Fig. 2(b) filled in with the designations for an Intel 8008 computer.



However, a more sophisticated system used in many applications would be to use a teletype machine or a combination of a keyboard and a cathode-ray-tube (CRT) display attached to input and output ports to serve as the primary means of I/O. A person can thus type information on the keyboard which will pass it into the computer, and the computer can display the results of its operations on the CRT display (which can, incidentally, be made from an ordinary oscilloscope and a special CRT interface unit such as that described in Jim Hogenson's article in BYTE #2).

Perhaps the most wonderful and exciting aspect about a digital computer is its tremendous versatility. It has been said that the computer is the most versatile machine in existence and that its applications are limited only by man's ability to develop programs that direct the operation of the machine. It is undoubtedly one of the best machines for allowing man to exercise and test his creative powers through the development of programs that direct the machine to perform complex operations that can not only control other machines, or perform calculations many times faster than humanly possible, but because it can be used to "simulate" or "model" other systems that it might be impractical to build for purely experimental purposes. Thus man can create a "model" in a computer program and actually "play" with the synthetic model without actually building the physical device!

The computer's great versatility comes about because the machine is capable of executing a large group of instructions in an essentially limitless series of combinations – these series of instructions are stored in the memory bank(s) of the computer – and a new series of instructions can be placed in the memory bank(s) whenever desired. In fact, the memory bank(s) can often hold several completely unrelated "programs" in different sections and thus one can have a machine that performs totally unrelated tasks simply by pushing a few buttons and thereby directing the machine to start executing a new program in a different section of memory!

The digital computer is capable of providing services to people from all walks of life! A person need only choose (or develop) programs and connect external instruments that will provide the capabilities desired.

For instance, a scientist might put a mathematical calculator program into the

computer's memory and use the computer as a sophisticated electronic calculator by using a calculator-type keyboard as an input device and a CRT display as an output device on which to receive the answers to complex mathematical calculations which the computer performs. After using the computer as a calculator for a period of time, the scientist might decide to utilize the same computer to automatically record data from instruments during an experiment. By simply putting a different program in the computer's memory and plugging some peripheral measuring instruments into the computer's I/O ports, the scientist could have the computer periodically make measurements while he went out to lunch and save the results in its memory. After lunch the scientist could have the computer tabulate and present the data obtained from the experiment in compact form. Then, by merely putting a different program in the memory, the scientist could have the computer help him set up and arrange a "reference file" all sorted into alphabetical order or any manner that would enable him to use the computer to extract information far faster than a manually operated "paper file card" system.

So the computer can be a valuable tool for a scientist; but, the same machine with a different program in its memory (and possibly different peripheral devices) could be used to control a complex manufacturing operation such as a plastic injection molding machine. In such a case I/O units that coupled to transducers on the injection molding machine might be used to relay information to the computer on a variety of parameters such as temperature of the plastic in the feed barrel, amount of feed material in the hopper and injection barrel, available pressure to the mold jaws and feed barrel, vacancy or filled status of the mold and other useful parameters. The computer could be programmed to analyze this information and send back signals to control the operation of heaters, pressure valves, the feed rate of raw materials, when to inject plastic into the mold, when to empty the mold, and other operations to enable the plastic injection system to operate in an essentially automatic mode.

Or, a businessman could use the same computer connected to an electric typewriter, with a suitable program in memory, to compose, edit and then type out "personalized form letters" by directing the computer to insert paragraphs from a "bank of standard paragraphs" so as to form a personalized customer answering system that would handle routine inquiries in a fraction of the time (and cost) that it would take a secretary to prepare such letters. Or, the businessman might utilize the computer to help him control his inventory, or speed up his accounting operations.

However, a computer that costs as little as the typical micro system does not have to be restricted to a business or scientific environment. The computer that can do all the types of tasks mentioned above can also be used to have fun with, or to perform valuable services, to private individuals.

The computer can be used as a sophisticated electronic calculator by almost anyone. It can be used to compose letters (using an editor program) by virtually anyone. Programs that sort data alphabetically or in various other categories can be of valuable service to people in many applications. The computer can be used to monitor and control many household items, serve as a security monitoring system, be connected to devices that will dial telephones, and do thousands of other tasks.

The electronic hobbyist can be kept occupied for years with a digital computer. For instance, one can build a little test instrument that plugs into a few I/O ports on the computer, then load programs into memory that will direct the computer to automatically test electronic components (such as complex TTL integrated circuits) in a fraction of a second! (Businesses can do this too!)

Or a ham radio operator can put a program into memory that will enable the computer to receive messages typed in from a keyboard, convert the messages to Morse code, and then actuate an oscillator via an output port to send perfectly timed Morse code. In addition, the ham radio operator might use the computer with an appropriate program to serve as a "contest logging aid." The "logging aid" would serve as an instant reference file whereby the operator could enter the calls of stations as they were worked and have the computer verify if the contact was a duplicate. The computer could do other tasks too, such as record the time of the contact by checking an external digital clock (or by utilizing a program that would enable the computer to be used as a clock within itself)!

And, the computer can be used to play numerous games with, such as tic-tac-toe, checkers, word games, card games, and a large variety of other types of games that one can program a computer to perform.

And perhaps most important – for the student, hobbyist, scientist, businessman, or anyone interested in the exciting possibilities of its applications – the contemporary microcomputer offers unlimited possibilities for the expression of individual creativity. For the development of computer programs can be an extremely creative, exciting and personally rewarding pastime and offers essentially limitless ways to exercise one's creative capabilities in developing "algorithms" that will enable the machine to perform desired tasks!

The development of computer programs can be an extremely creative, exciting and personally rewarding pastime and offers essentially limitless ways to exercise one's creative capabilities . . . .

The electronic hobbyist can be kept occupied for years with a digital computer.

The Micro-Sphere 200 Series computer is the most ADVANCED, low-cost computer SYSTEM available today. Together with a TV and up to three cassette recorders you can have big computer performance at a rock bottom price.

The system features a 6800 type micro-computer with 4000 characters (4K Bytes) of internal Random Access Memory (RAM) Storage. The memory is easily expandable to 8000 total characters with the addition of an optional second 4K of RAM, with even more memory to be made available shortly. The 4K bytes of memory is equivalent to 6-8 pages of close typewritten material.

Access into the Micro-Sphere is achieved by the keyboard or from cassette recorders. The computer can display information on a standard TV screen (optionally supplied) or store information on a cassette recorder.

The keyboard uses highly reliable keyswitches to insure user satisfaction. It is full alpha-numeric including an integrated numeric key pad. The cassette interface uses the "Kansas City" standard which means that you can use even the least expensive cassette recorders with your system satisfactorily though we suggest that you do use high quality tapes with your system.

You may use your own TV without modification as the system display device, or you may purchase one from Sphere.

The power requirement is a single 110 volt AC outlet. The unit uses less power than an ordinary 100 watt light bulb. All fuses, jacks, switches, and interface signals are provided on an easy-access panel at the rear of the cabinet.

The Micro-Sphere is supplied with a built-in loading program from cassette, which is in one of the several standard or optional Read Only Memory (ROM) Integrated Circuits (IC). ROM IC's are pre-programmed with specific non-eraseable information. This feature greatly reduces program loading time and inconvenience, ROM's also save valuable RAM storage. RAM's lose all stored memory whenever the computer power is turned off, while ROMs retain all programs indefinitely.

The Micro-Sphere is unique in that 16,384 different dots on your TV screen can form any number of pictures or designs which you have instructed your computer to display. These images can be changed by the computer program at a rate that appears as real-life movement, such as aircraft flight simulation, "walk-through" inspection of architectual mock-ups, time-lapse stock market graphic analysis, or even computer generated art forms, or space flight simulation where you can guide your spacecraft to the moon, planets or the universe.

You can experience the thrill of rolls, dives, loops, near-collisions and other types of aerial maneuvers to out wit the Red Baron in your Sopwith Camel and then the excitement of a victorious landing as you crash at the end of the approaching runway.

This same 128 row by 128 column dot matrix can form an alpha-numeric display of up to 16 lines by 21 characters. An optional graphics input device (Mouse) digitizes hand movements when moved about on a flat surface. The "Mouse" has a window and crosshairs, so it may be used for the accurate entry of maps or other graphic data. The mouse may also be used in the place of a joy stick for flight simulation or to enter hand movements for ping-pong or other games of skill.

Sphere Corp. has included in the basic price of the Micro-Sphere 200 the Monte Carlo games package on cassette, which allows you to play blackjack, roulette, and other games just for fun.

The Sphere Cassette Operating System (SCOS) is supplied on tape and provides Assembler, Edit, and Debugging functions to the computer when read in to RAM from the Cassette. Sub-routines for floating point and trig functions are included in the SCOS cassette and may also be purchased as an option in ROM. Sub-routines are included in SCOS which provide all necessary alpha-numeric character generation for your TV using approximately 400 bytes of RAM. An optional character generator ROM can be purchased to reduce RAM usage to 50 bytes. SCOS also supports file handling.

If the second 4K of RAM is purchased the macro facility of the assembler is then available as an extended aid to help you in the development of your own programs. The second 4K of RAM will also allow you to read in extended Business Basic from cassette. This basic provides 16 digits of decimal accuracy and extensions for business use. This Business Basic can make use of the Floating Point and Trig Package in RAM or ROM to expand its capabilities into the engineering field. The Business Basic and Trig Packages are available in ROM, which leaves all of the RAM storage available for applications written in the Basic Language. This is a concept for which you may pay $9,000 to get from an IBM 5100 computer.

One Cassette recorder is sufficient to do everything by simply changing tapes. Multiple file handling such as inventory control, pay roll, and general ledger processing etc. will be more convenient if two or even three cassette recorders are used. For example tape #1 may contain the last year-to-date accumulation file, tape #2 may contain the present pay period account, while tape #3 is used to combine tapes #1 and #2 into a new year-to-date accumulation master file. The second and third Cassette Interface options are available for those who require them.

In the near future, Sphere will release a Programmable Input/Output Controller for use with printers, disks, and other input/output devices.

The attractive two-tone case is made of mar-resistant high impact plastic designed to fit any modern decor. Additional strength and protection to components is provided by an internal metal chassis.

The unit is designed to operate in a normal home or office environment without any extra care. The Micro-Sphere is the product of many years of experience in the micro-computer field, providing a tremendous amount of power and capability in the smallest space-it requires only a small desk with space left over, and it comes fully assembled and tested--ready to use.

SPHERE CORPORATION
791 South 500 West Bountiful, Utah 84010 801 292-8466

PRICES FOR MICRO-SPHERE 200 WITH OPTIONS

No.	Description	Price/Each	Total
200	MICRO-SPHERE 200 - SYSTEM PRICE INCLUDES "A" ITEMS BELOW	$ 860.00	$ 860.00
	"A" ITEMS: 6800 type Micro-Processor unit		
	4K of Memory (RAM)		
	Cassette Loading System (ROM)		
	Sphere Cassette Operating System (SCOS) Cassette 1 time license fee@ $137.50		
	Includes Floating Point and Trig Package Cassette copy @ 12.50	$150.00	Incl.
	Monte Carlo Games Package (Cassette)	$10.00	Incl.
	First Cassette Interface		
	128 by 128 B&W Dot Matrix Graphics Display		
	Alpha-Numeric Keyboard		
	Attractive Mar-Resistant Plastic Case		
	Operators Manual		
	OPTIONS AVAILABLE THROUGH FACTORY INSTALLATION.		
	* To install options after purchase is $35.00 per shipment to our plant.		
	"B" ITEMS: Second 4K of memory (RAM)	$180.00	$180.00
	Character Generator (ROM)	$25.00	$25.00
	"C" ITEMS: Second Cassette Interface	$50.00	$50.00
	Extended Business Basic (ROM)	$400.00	$400.00
	Includes Business Basic Manual		
	Floating point & Trig package (ROM)	$130.00	$130.00
	Third Cassette Interface	$50.00	$50.00
	OPTIONS FOR PURCHASE NOT NEEDING FACTORY INSTALLATION.		
	Extended Business Basic on Cassette (Requires 2nd 4K of RAM and Character Generator in ROM.) Includes Business Basic Manual, Floating Point & Trig Package	$100.00	$100.00
	9" TV for use with Micro-Sphere 200	$150.00	$150.00
	"Mouse" Graphics Input Device (Available in May 1976) 2 ea.	$150.00	$150.00
	Operators Manual (SCOS)	$10.00	$10.00
	Business Basic Manual	$10.00	$10.00
	Maintenance Manual	$40.00	$40.00
	Empty Cassette Tapes 3 for	$10.00	$10.00
200A	INCLUDES MICRO-SPHERE 200 PLUS ALL OF "A" ITEMS ABOVE	$860.00	$860.00
200B	INCLUDES MICRO-SPHERE 200 PLUS ALL OF "A" & "B" ITEMS ABOVE	$1065.00	$1065.00
200C	INCLUDES MICRO-SPHERE 200 PLUS ALL OF "A" & "B" & "C" ITEMS ABOVE	$1695.00	$1695.00
	EVERYTHING IS IN ROM !!		

ALL UNITS ARE COMPLETELY ASSEMBLED AND READY TO USE!!

A Versatile TTY Generator

A short time ago, an old Model 15 Teletype machine was, so to speak, left on my doorstep. I wanted to see it do something, and was not satisfied with pounding on the keyboard. Since I did not have the proper terminal unit and receiver combination to copy off the air, I asked myself what kind of a simple test device could be made that would make the machine print. I set to work thinking that an RY generator should not be too hard, but much to my surprise I came up with a nifty little unit which is inexpensive to build and yet will print every key and function on the Teletype machine. Not only will it print a test pattern testing *all* figures and letters, but it will also take an input from an external source, such as a memory device, and will generate useful TTY signals. With a simple interface, this unit may be run directly from a solid state keyboard.

The scope of this article will be to present a basic TTY generator which is not only a useful test generator, but may also be expanded into a complete transmission system with memory.

The heart of the system is a data selector (IC-5), and counter (IC-2&3). The data selector has eight inputs and one output. The output is connected to any one of the inputs, and the selection is done by the BCD code applied to the selection inputs. If the BCD code 000 is applied, the output is connected to input X0. If the BCD code is 100, input X1 is selected, and so on. The counter is an eight bit counter consisting of a CD4024 7 stage counter, and ½ of a CD4013, adding the 8th stage. This counter is stepped by the output of an oscillator which steps the counter every 22 ms (refer to Fig. 1). The first three stages, Q1, Q2 and Q3, are connected to the selection inputs of the data selector, causing the output to scan each input at a rate of one input each 22 ms. The inputs of the data selector are wired so that X0 is always low, X1 is always high, and X7 is always low. This leaves inputs X2-X6 open for data. For ease of explanation, we will assume the open inputs are low, the counter has been sitting, reset, at count zero. Input X0 is selected causing the output of the data selector to be low (mark). The oscillator and counter are enabled and 22 ms later input X1 is selected causing 22 ms of high (space), the start pulse, to be output. Since the next five inputs are low (assumed) the next 110 ms (5 x 22 ms) will be low (mark). Now the 8th input is selected and it is always low. If the circuit as described were allowed to continue to run, each cycle would consist of 22 ms of space and 154 ms of mark. If this were applied to a Teletype machine, the repeated LTR function would be observed. If the five (X2-X6) data inputs were

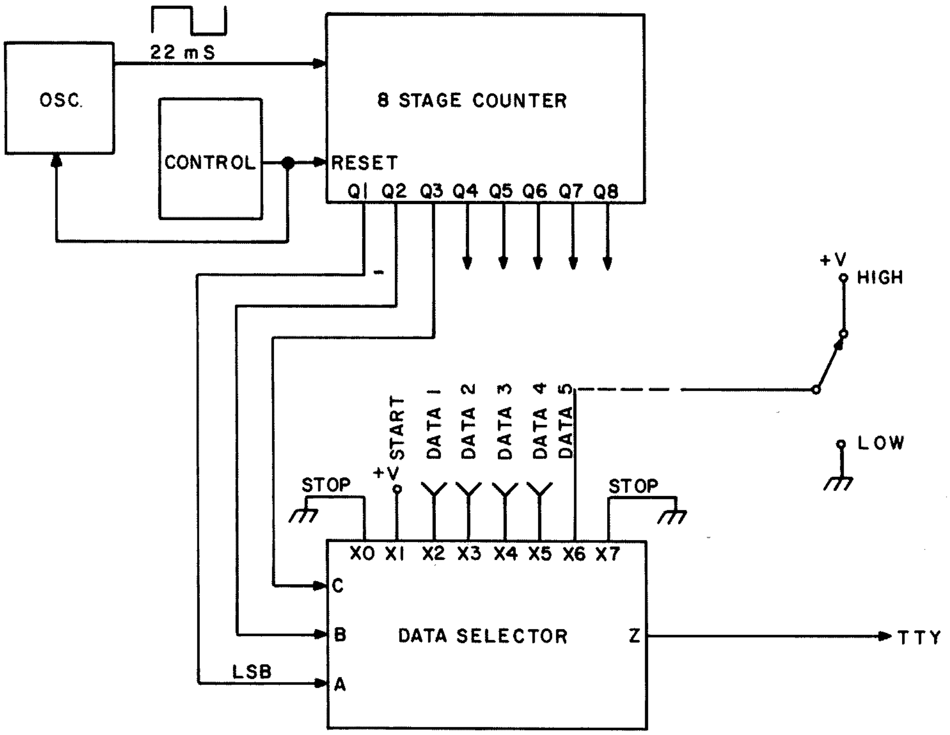

Fig. 1.

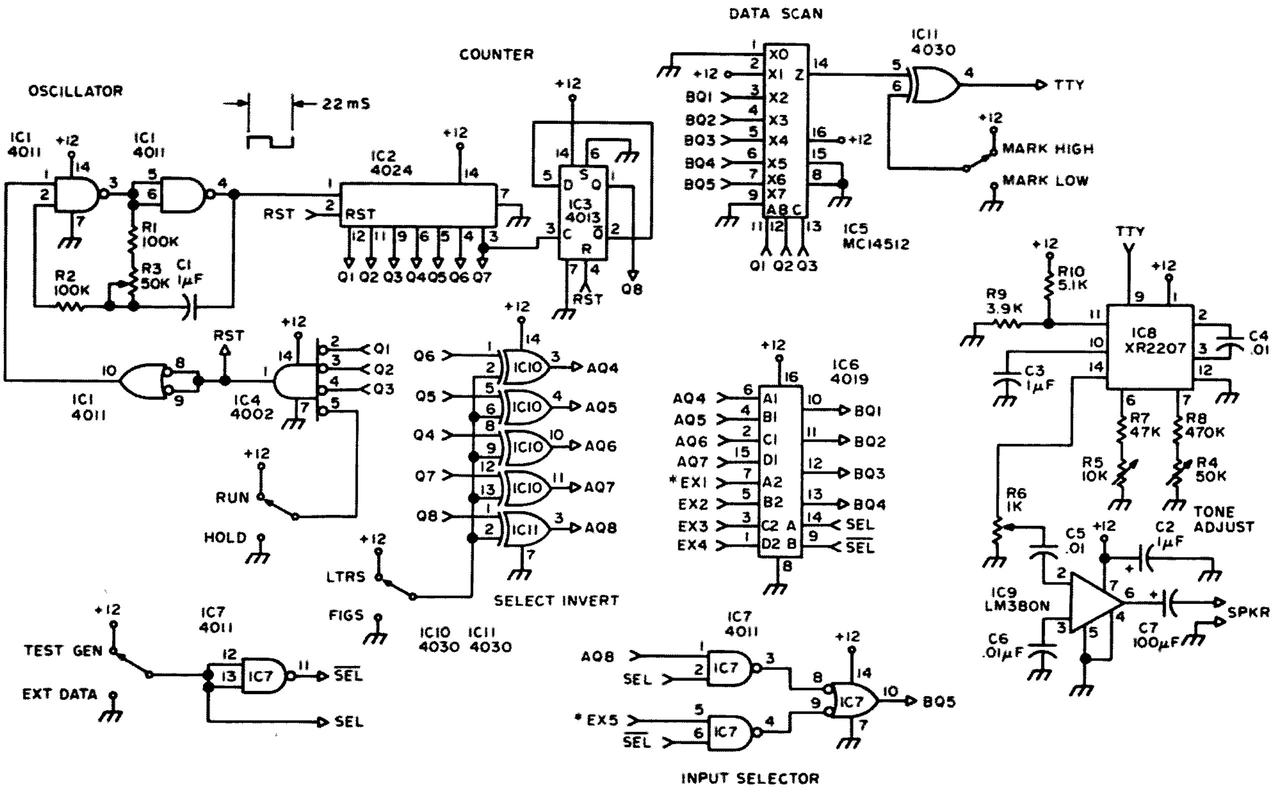

*Fig. 2. *Note: Terms EX1-EX5 have no source, but are provided as inputs for external data, or switches.*

connected to switches so that a high or low could be placed on each input, each combination of the switch settings would produce a different character or function. Going a step further, we will now connect each of the five data inputs to one of the five remaining counter outputs (Q4-Q8). As can now be observed, each pass, or scan, of the data selector will have a different combination of data for the five data bits. Again, if this were applied to a Teletype machine, it would be observed that each full cycle would consist of every key (every code) being "hit" once. Some of these characters would be upper case, and some lower. It is desirable to have all upper or all lower case characters, and if counter outputs Q4 and Q6 are interchanged, we will get this. As described, the printing would be all upper case (since the letters function is followed by the figures function). If all five bits are inverted, all will be lower case because figures is now followed by letters.

To select which polarity of signal is sent to the data selector from the counter, each bit is passed through an "Exclusive OR" gate, which will be used as an invert select function. The counter bit goes in one input, and the control signal in the other. If the control input is high, the gate will invert and the print will be all letters. If the control input is low, the gate will not invert and all figures will be printed. Now there are two selectable patterns consisting of all letters (entire alphabet), or all figures. In both patterns there is a carriage return and a line feed so the paper does not overprint, but since there is no delay after a carriage return, some machines will print the first letter of the line before the carriage has fully returned, causing a single character overprint.

To add the final touch to this circuit, a data selector will be used to select the data source. If the control signal is low, the five inputs, which can come from anything from static switches to memory, will be selected. If it is high, the internal test pattern data are selected. Also added will be a selectable inverter on the TTY output so mark high or mark low may be selected, and also a simple ASFK oscillator and audio amplifier.

When built with the values shown, this circuit will provide audio tones of 2125 Hz and 2975 Hz, and will drive a loudspeaker to ear-splitting volume. ■

Parts List

IC-1	CD4011	RCA	Quad 2 Input NAND Gate
IC-2	CD4024	RCA	7 Stage Counter
IC-3	CD4013	RCA	Dual D Flip Flop
IC-4	CD4002	RCA	Dual 4 Input NOR Gate
IC-5	MC14512	RCA	8 Input Data Selector
IC-6	CD4019	RCA	Quad AND/OR Select
IC-7	CD4011	RCA	(SEE IC-1)
IC-8	XR2207	EXAR	Voltage Controlled Oscillator
IC-9	LM380N	NAT	Audio Amplifier
IC-10	CD4030	RCA	Quad Exclusive OR
IC-11	CD4030	RCA	(SEE IC-10)
R1-R2	100k ¼ Watt Resistor

C1-C3	1 mF 16 volt Capacitor		
C4-C6	.01 mF Disc Capacitor		
C7	100 mF 16 volt Electrolytic Capacitor		

I/O

from page 65

of reading of *73* articles (many of which are not even written yet) you will be plain high and dry trying to fathom what these strange folk are trying to say in their weird new language.

My Computer Likes Me (when I speak in BASIC) by Bob Albrecht. Dymax, Box 310, Menlo Park CA; 64 pp., $2.00.

BASIC (A Self-Teaching Guide) by Robert L. Albrecht, LeRoy Finkel, and Jerald R. Brown. Wiley, New York; 324 pp., $3.95.

The most popular computer language for both small systems and time-sharing is BASIC. It is a powerful language, yet easy to learn, and is fast being adopted as the standard language for hobby computer program exchange. The computer novice who purchases a microcomputer will probably want to obtain a BASIC operating system for his computer, as it speeds up programming immensely.

These two textbooks are very different in scope and approach, though both are authored by Bob Albrecht of the People's Computer Company. *My Computer Likes Me* is written as a simplified approach for rank beginners, and seems aimed at the secondary school user with a classroom terminal. The approach is friendly, informal and light, with plenty of examples to show every step of the way. Only the fundamentals of BASIC are covered, with a demonstration of mathematical modeling to predict population. For a student with an innate fear of the computer and what it takes to understand one, this simple text is perfect to break down that first barrier.

BASIC (A Self-Teaching Guide) takes a more sober approach and goes much farther. Programmed teaching, with step-by-step questioning of the student, punctuates the text into individual concepts, none of which intimidate the student the way a less cautious text can. After explaining input and output, arithmetic, and simple logical statements, the more sophisticated capabilities of BASIC, such as matrix arithmetic and string (character) operations, are cautiously introduced. After completing the text, the student should feel competent to handle most problems that can be solved with BASIC and a small computer.

No text in programming is really complete without a computer to practice on, and the versions of BASIC that different manufacturers supply are not all identical to any textbook. But no manufacturer's reference book takes the time to start a new programmer off on the right track without major confusion — unless perhaps he's a genius. For a timid user, *My Computer Likes Me* would be ideal as an appetizer, but *BASIC (A Self-Teaching Guide)* provides a main course for the hungry learner.

What to Do After You Hit Return (or, PCC's First Book of Computer Games). People's Computer Company, Menlo Park CA; 158 pp.

Computers are fantastic toys, and the best thing about them is that they can be made to do so many different things, so you never really get bored. Especially with this book, which includes fifty different games you can play on a computer that speaks BASIC. These were developed on the Hewlett-Packard 2000 minicomputer system, and the programs were all tested by H-P personnel. Many have been circulating for years; some are quite recent.

There are number games, word games, pattern games, board games, simulations, and even science fiction games. *Nim, Lunar Lander, Star Trek, Madlib, Bagels*, and most other popular computer games are included. Rules are explained, sample runs are shown, and in most cases, program listings are included (in BASIC). Most can be played without a computer if you're so inclined, but the hardware is half the fun, right?

What to Do After You Hit Return is big and attractively put together on giant pages that stay open on the table. It's the software equivalent of a barrel of monkeys. See why most colleges find that most of their computer time is spent playing games!

Games, Tricks and Puzzles for a Hand Calculator by Wallace Judd. Dymax, Box 310, Menlo Park CA 94025; 91 pp., $2.95 + .50 postage and handling.

Even when I read old "fun with math" books I didn't think mathematics was fun. Now I know what was missing. This book updates the old number tricks by using calculators to do the dirty work. Suddenly math *is* fun — with the machine. *Games, Tricks, and Puzzles . . .* includes simple mathematical tricks that even children would appreciate, as well as more complicated exercises that require some high school algebra. They are explained in order of complexity.

There are also the calculator "word" games played by turning the calculator upside down, a photo story on how a calculator is made, and information to help evaluate calculators prior to purchasing one. Answers to the puzzles are in back, along with explanations of how they work. Impress your friends. You may even impress yourself!

Chariots of the Hams?

Anyone who is aware of the history of mankind realizes the enormous engineering capabilities that some of the ancient civilizations held. Both the Greeks and Romans devised *ingenious* inventions to benefit their respective cultures.

Professor C. Q. Flugalsnort (alias Dan WN0OZW), crack archeologist, checks out an obviously primitive ham rig at the digging site.

But of course we all know that they weren't so advanced as to allow a citizen of Athens to jump into his chariot and key up the local repeater mounted on the nearby Parthenon. And we all know that it would be stupid to expect to find an FET stuck in one of the hoofs of the Trojan Horse. That would be just plain dumb, wouldn't it? Or would it? Better wait to decide until you've read this story of an ancient civilization that may have some lessons for all amateurs!

It all started one clear fall afternoon as our college ham club was holding its annual transmitter hunt and "refreshment hour." One of the guys had already found the transmitter – hanging from a shower nozzle in the fifth floor bathroom of the women's dorm. Tracking down the transmitter hadn't been the toughest part of the hunt – retrieving it from its ingenious hiding place with-

out getting caught was what took guts!

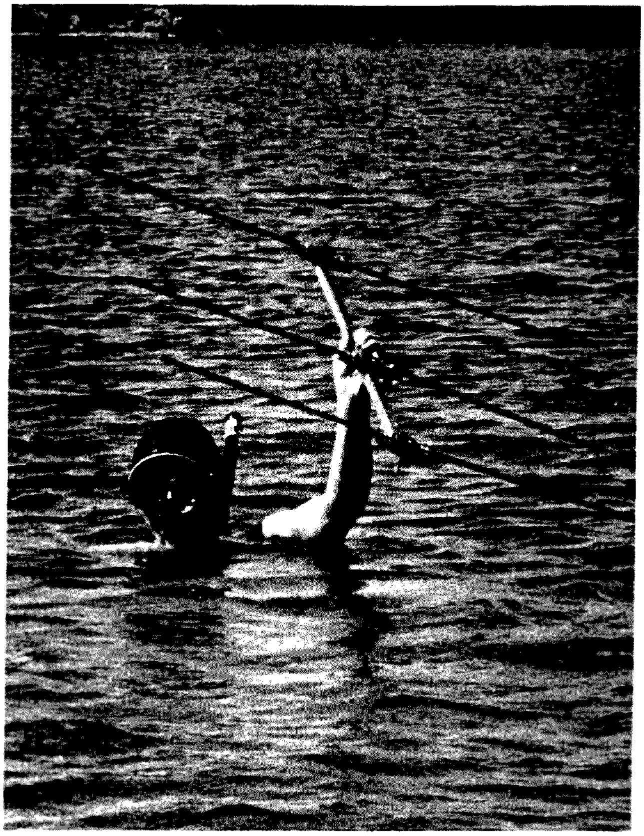
But anyway, it turned out that two of our club members had started their personal "refreshment hour" a few hours before the hunt even started, and had somehow ended up sauntering through a field some 10 miles away from the transmitter. Upon returning to the festivities, they claimed that they had been led astray by some freak harmonics from the airport VOR. But we knew better. To make matters even more ridiculous, they claimed to have tripped over a mike cord coming right out of the ground!

That's right – right out of the ground!

"Sure," we all said, having a nice chuckle over this bit of QRM. But the guys kept insisting that they were telling the truth, and pretty soon the refreshment hour had been in progress long enough for everyone to want to take a look at this place. Needless to say, we tied up the repeater with talk of this on the way out to this field, and also needless to say, every other guy in town listening thought we were nuts.

But sure enough – coming right out of this field was a mobile mike and coiled cord. We quickly checked the club records to see if we had ever had a party out here; no, we hadn't. (The possibility of a rig getting buried at one of our club parties wasn't to be overlooked, although I don't think this is what they were talking about in the recent *73* article on underground radio transmissions.)

The whole thing was so darn funny that pretty soon we had half the hams in town tromping around in this field. Shortly, one of the guys tripped over something about 30 yards away from the mike cord coming out of the ground. We all ran over.



Ham scuba diver from our college ham club pulls "fossilized" 2 meter beam out of lake. Was there an ancient civilization of ham operators, and if so, did they disappear because of incentive licensing?

Flugalsnort (note puzzled expression on face) checks out mobile mike coming right out of the ground.

"Darn if that doesn't look like a two meter beam," he said, "but it looks like it's fossilized!"

Well, we all had a good laugh over this obvious prank and headed home to recharge our hand-helds and finish the "refreshment hour," which by now was becoming something more like a "refreshment day."

I awoke bright and early at 12 noon the next day to the ringing of the phone. On the line was Professor C.Q. Flugalsnort, our college's crack archeologist. Prof. Flugalsnort had heard from somebody about the strange things discovered in the field the night before. I tried to explain that it all had to be a joke pulled by someone, because one just doesn't find real fossilized two meter beams laying around in cornfields.

But Flugalsnort insisted that we had to go out and take a look. I agreed to meet him at the field, but just as I was leaving the phone rang – it was a member of the club reporting that scuba diving that day in a nearby lake he had come across another fossilized beam! Either somebody was going to an awful lot of effort to get some laughs, or we were really on to something strange.

I rounded up the rest of the club and we headed back out to the field with an assortment of shovels. Not to pass up an opportunity like this, two members of the club were already drawing up proposals to submit to the dean for us to get a full class credit in archeology for digging up

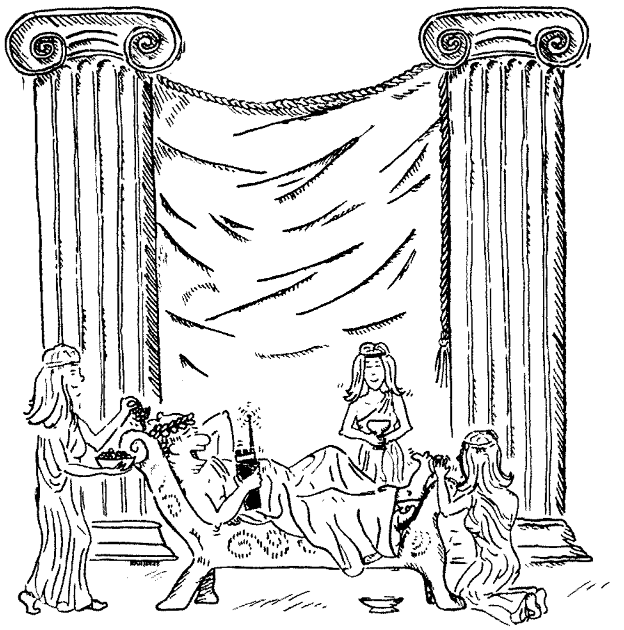
this field. (Which reminds me of the time I tried to get a class credit in physical education for hauling a 20 meter beam up a 75 foot tower alone; I deserved it. But that's another story . . .)

Anyway, Professor Flugalsnort met us at the field. Flugalsnort is the kind of guy who, if you ever saw him coming over your SSTV screen, would cause you to slap the side of your rig to see if something inside was loose.

We dug around in the cornfield for awhile with Flugalsnort on his hands and knees certain that he was about to make the biggest archeological splash since he'd delivered his paper on the plumbing of ancient fountains before a Chicago convention.

As he galloped around, the rest of us were having a difficult time resisting some 20 over S9 laughter. The two guys who had originally discovered the place had just confessed in whispers that it was their little joke on Flugalsnort all along. It seemed to the guys that a little comic revenge was in order on the professor after he had refused to let our club run antenna coax through his office window pane back at school. Seems that he unjustly thought our rigs were causing him TVI problems at home (we checked it out), and to make matters worse, he even drilled the pane himself (just the right sized hole) and hung a sign over it saying, "NO COAX." What a creep.

Well, after digging a bit more we decided that we had had our fun and started to convince the professor to give it up. We had just about accomplished this when suddenly one of our shovels went "clunk" on something in the ground. This was really funny because the guys hadn't mentioned anything about planting something else in the field. We were all too stunned to see the slight grin on Flugalsnort's face as he slowly pulled a large and ancient-looking stone slab out of the ground with the drawing below on it . . . ■



Mysterious drawing on stone slab pulled out of ground at digging site. Does the fellow on the couch resemble a well-known ham editor from New Hampshire hard at work?

The PLL - EXPOSED!

The phase locked loop is not a new concept. But before integrated circuits, the PLL was an expensive and cumbersome device. Using vacuum tubes, chokes, and other "ancient" components, it was a mess.

The simplest PLL consists of three internal units: a phase detector or comparator, low pass filter and voltage controlled oscillator. They are connected in a loop (Fig. 1).

The Phase Detector

A phase detector (also called comparator) monitors the frequency of its input. When a change in phase (therefore frequency) occurs, it will cause a corresponding change in its output voltage. This change of output is immediate and linear. If we watch the output voltage we can tell if a frequency change was happening at the input.

In the crudest form it can be an exclusive OR gate. Fig. 2 shows the inputs and corresponding outputs. (See July, 1975, "How Gates Work," for details on the exclusive OR gate.) The action of the RC network on the output yields the error voltage.

The Low Pass Filter

The action of a low pass filter is well known. Suffice it to say that PLLs have provisions for parts of the filter to be internal and others to be external. For example, the 565 chip has an internal resistor and external capacitor forming the filter.

The Voltage Controlled Oscillator

The VCO is a complex device. As the name implies, it is an oscillator. Its task is to change its output frequency when input voltages change, the opposite of the phase detector. The output frequency will increase as the input voltage increases. To do this, however, the input voltage must increase past a known value called the "threshold voltage." The input is then known as the "control voltage." With no input it operates at a "free running" frequency (f_o) determined by external adjustments.

The Set Up

Here is what happens. If the input frequency changes, the output of the phase comparator increases or decreases. This voltage change is fed through the filter which eliminates extraneous noises and passes the signal to the VCO. This change at the VCO input will alter the output frequency such that its value will be closer to the free running frequency. And the system goes 'round and 'round until the loop is locked on the incoming signal. Reinforcement takes place.

In other words, we set the PLL to search for a certain frequency. When that special frequency is seen, the system works to keep it locked in. The error voltage is then zero and the PLL output goes low. (Does the name phase locked loop make sense now?)

Obviously, the input source, whatever it is, is independent of the PLL, but the action is such that the signal we desire is there even if it disappears for short periods of time. It works as a "flywheel effect" does. How long can it disappear and still have a locked condition? Or, to put it another way, how long does it take to realize the desired signal is there and lock on it? This is related directly to the natural frequency of the loop. The lower it is the longer the lock up time. It is therefore a function of the low pass filter. We adjust the filter for our conditions depending upon how fast our information is. If we are transmitting very fast information, we must have a fast lock up time. If the lock up time is too great (meaning slow), we will lose too much data while our loop is taking its time locking up. Less information speed gives us a greater leeway. It's a tradeoff. We want our filter as low as possible to exclude unwanted noises in our loop circuit, yet fast enough to keep all information intact.

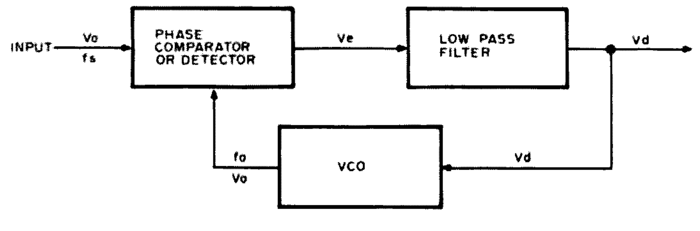

Fig. 1. Phase locked loop.

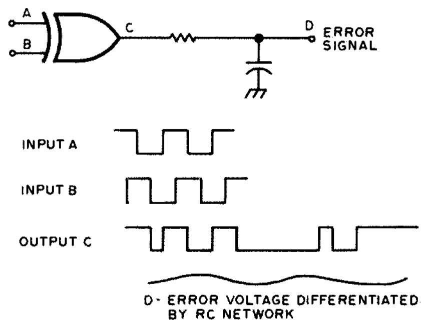

Fig. 2. Exclusive OR gate as a phase comparator.

When the input frequency (f_s) is close to the free running frequency (f_o), the VCO will synchronize and lock. But how close must they be? Just how large is this "capture range"? On most PLLs it is adjustable. It is a function of the input voltage, free running frequency and low pass filter. Equations for figuring capture range are given in PLL specs. Other names which are used are "acquisition range" and "bandwidth."

Once the loop is locked, how far can the input stray before it loses lock? This feature known as "lock range" is larger than the capture range. Once the loop is locked, the input can wander quite a way (relatively speaking) before the PLL will lose its grip. It is also called the "tracking" or "holding" range. The lock range is usually given as a percentage of the frequency. The larger the percentage, the further the input can move before the PLL unlocks. Again, very exact and easy equations are supplied in specs to compute the tracking range.

As an example, we might design a PLL to look for a touchtone signal. We would keep in mind that the capture range must be wide enough to accommodate those signals that might be slightly off frequency but still narrow enough to prevent the wrong numbers from activating our device.

Tracking range would not figure very heavily (again, relatively speaking) in our design as the tones must only be detected for a short time to be effective.

Applications

As we said before, the output dc level of the phase comparator is proportional to the frequency of the input signal at lock. As the frequency shifts, the signal to the VCO changes linearly. If we can track over a large area (about ± 60%) with linearity, we have *FM demodulation.*

The 565 is a good PLL to look at (Figs. 3, 3a). The free running frequency is determined by $f_o = \frac{1}{4} R_1C_1$. It is adjusted for the center of the input signal frequency range. The 565 also has an amplifier to increase gain of the loop – a good feature. C_3 prevents unwanted oscillations by inhibiting any feedback to the power source. The reference voltage (pin 6) is a voltage close in value to the average dc output of the demodulated signal. By connecting it to the output we can lower the gain of the loop with very little loss of output amplitude. Since the lower the gain the smaller the lock range, we can decrease the lock range without leaving too small an output to use.

C_2 is the low pass filter capacitor. It is coupled with an internal resistor of 3.6k.

Frequency Multiplication

Frequency multiplication using PLLs is easier than you may suspect. There are two methods in use. The first requires that the PLL be set to look for an harmonic of our input. If we set the VCO for the second harmonic of a signal, the completed loop will lock onto it. For all intents we have multiplied a frequency. Of course we are limited to signals rich in harmonics. We are also held captive to the first few harmonics as harmonic strength decreases with harmonic number. Loop amplification is always used in this case.

The second method is also not difficult but does require some extra equipment. Insert a frequency divider between the VCO and phase comparator. The divided VCO frequency is locked to the input. Therefore, the VCO is running at the multiple of the input frequency. The multiple depends upon the divider value. The frequency limits of the inputs must be taken into consideration with both of these procedures. (Fig. 4.)

Frequency Synthesis

PLLs have made low cost, compact FM frequency synthesis a reality. In its simplest state (Fig. 5), a multiplier is used at the input. The PLL is used as an adding device because it has a very important characteristic which others lack – stability. By setting the loop to stringent criteria, the output can be kept to close tolerances with accuracy. The input (f_{ref}) reference frequency is supplied by a crystal oscillator. By adjusting a counter or similar divider we can select or "program" a choice of frequencies. The low pass filter gets rid of the $f_o + f_{ref}$ component which exists.

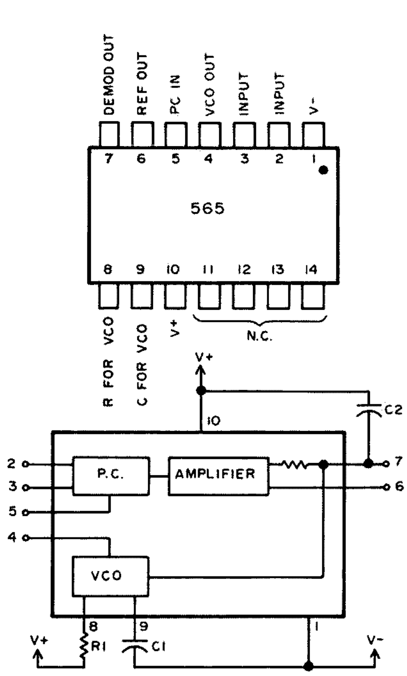

Fig. 3. 565 PLL chip.

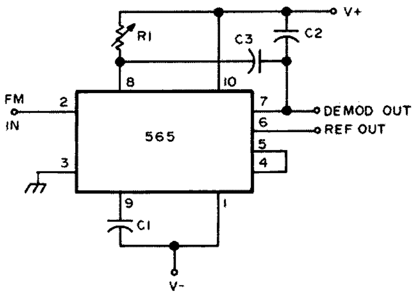

Fig. 3a. 565 PLL as an FM demodulator.

I hesitate to give exact block diagrams of synthesizers as work still continues on their design. I have seen and used many good ones, both home brew and commercial. But all leave something to be desired. This is not meant to be a criticism but a push for all experimenters to improve on current designs.

AM Detection

PLLs can also be used for AM demodulation. By using a special VCO or RC phase shifter network and another phase com-

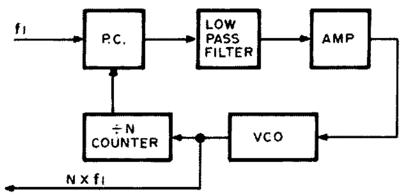

Fig. 4. Frequency multiplication.

parator, we can demodulate amplitude modulation. Internal operation is shown in Fig. 6 where the VCO output of 90° is changed to 0°. Or as in Fig. 6a where a whole new phase shift network is used. The 561 chip has an internal capability for AM detection along with its FM capability.

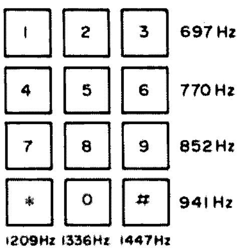

Fig. 8. Touchtones.

With the basic knowledge of the PLL, let's show how a touchtone decoder can be designed.

In order to fully design any system, all available information is needed. In this case, only the sections of the spec sheet which are necessary to this problem will be shown. Keep in mind that a lot more data is available to the user by the manufacturer.

The 567 PLL has shown to be ideal for touchtone decoding. Fig. 7 shows the layout. The "inside" view is given in Fig. 7a.

As you may already know, each digit delivers TWO tones simultaneously when pressed. Each row has a frequency and each column has a frequency. When a digit is pressed the two combine for our signal. A frequency chart is given in Fig. 8. It is therefore necessary to have two PLLs for each digit. There are a total of seven different tones. To decode the number "1" our PLLs must detect 697 Hz and 1209 Hz. The circuit is shown in Fig. 9.

The values of R_1 and C_1 are figured first. They determine the frequency of the loop. The equation is $f_o = 1/R_1 C_1$. According to the specs, R_1 should reside between 2k and 20k for best stability. In our case the top PLL will decode the 697 component, so good values might be R_1 = 6.8k and C_1 = .1 mF. To get the frequency right on the mark (our values yield 680 Hz), a potentiometer near the value of R_1 would serve nicely. Since all components have tolerances trial and error is the rule.

C_2 is part of the low pass filter. For this we use a graph supplied by the manufacturer. The graph in Fig. 10 shows bandwidth versus amplitude.

Decide the bandwidth you desire; find the input signal amplitude and pick off the value of f_oC_2. The equation for bandwidth is BW = 1070 x input voltage/f_oC_2; for inputs not greater than 200 mV, f is in Hz and C is in mF. Again, trial and error may be easier than the arithmetic.

If the input is 50 mV, f_oC_2 should equal 4.1 x 10^3 (4100) for a bandwidth of 4%. Therefore, C_2 would equal approximately 5.9 mF at 697 Hz. As we increase the tone values C_2 would get smaller because 4% of 1477 is larger than 4% of 697 Hz.

The next value is that of C_3. It sets the band edge which attenuates spurious outputs. Hence the name – output filter capacitor. If too small, it will allow frequencies near the detection range to beat against the output frequency and switch the output on and off. If too large, switching time at the output will be delayed as it charges. By experience it turns out to be equal to twice the value of C_2 or a bit more.

To make a touchtone decoder for all digits use the same techniques shown here. You may want to trade off values to get an average capacitor so you don't go nuts buying seven different kinds. And, you may decide to use only one value of rheostat for R_1, one that will satisfy all tones. Fine, no problem. But if you run into trouble, these design notes will help you out.

It is customary to have a high when the desired tone is pushed. The NOR gate at the output works fine because when the PLL locks, the error voltage is zero and a low is present. Both PLL lows presented to the NOR gate will give a high output. ■

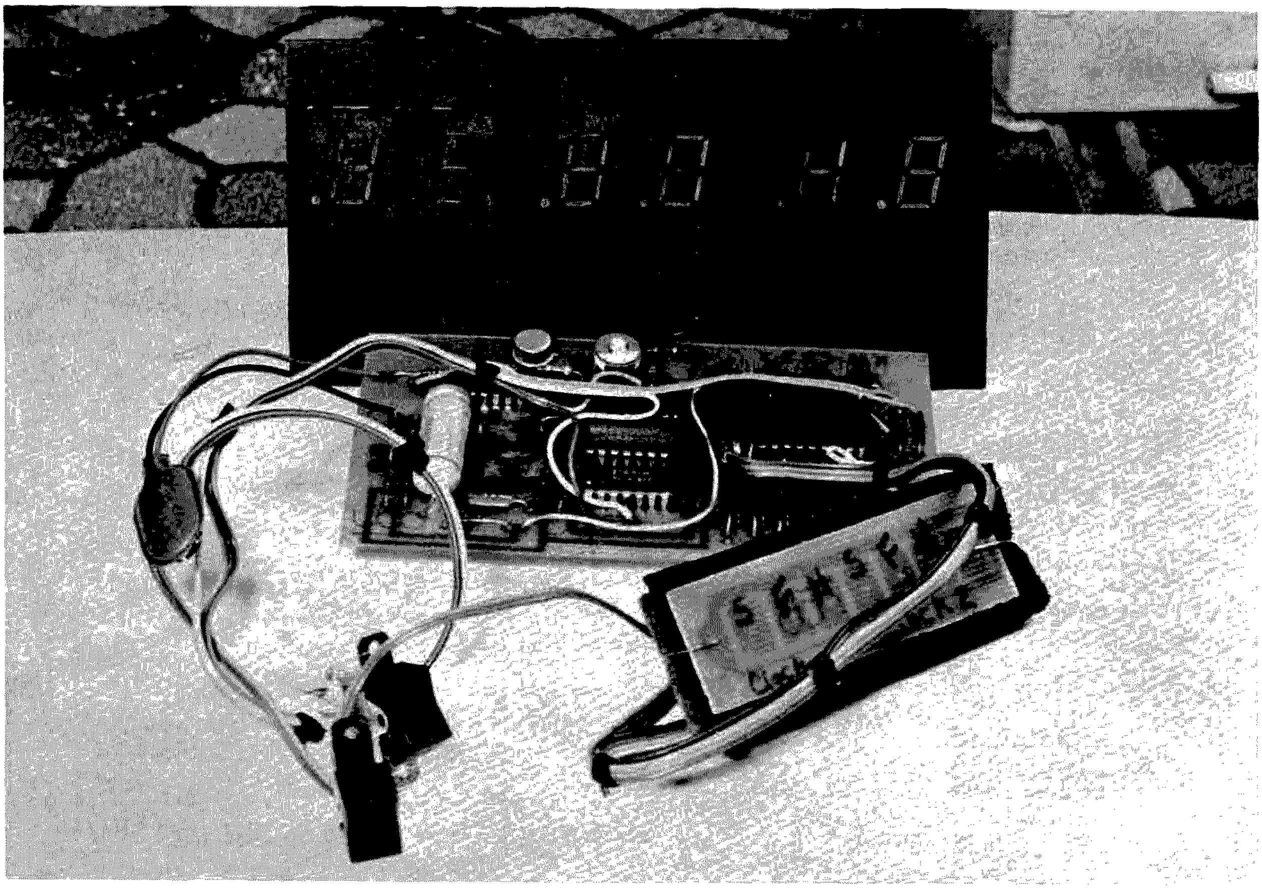
The Two-Timer

The two-time clock will display either of two different times and also flash the display at a one Hertz rate every ten minutes to remind you that it's time to ID. This clock can give you local time normally, and with a flick of the switch you have Greenwich Mean Time for operation and logging. The clock was designed with several things in mind: reliable continuous operation, two separate time display capabilities, a station ID reminder, and the ability to use several different power sources. A further qualifica-



tion was that all parts be readily available to the hobbyist/amateur from usual sources. The final design was able to fulfill all the qualifications.

Theory of Operation – Clock

The simplest way to understand this circuit is to treat it as if it were a single 5314 clock with the interfacing to drive common cathode LED displays. Complete details on this circuit can be found in the National Semiconductor MOS Integrated Circuits Book in the section covering the MM5314. The 60 Hz for time keeping and the 960 Hz for the multiplex frequency are obtained from the oscillator divider circuits.

All inputs and outputs for both ICs are in parallel except the output enables (pin 1), the time setting pins (pins 13, 14 and 15) and if desired the 12/24 hour select pin (pin 10). The output enable lines are used to enable the segment outputs from the desired chip. The resistors R_{12} and R_{13} act as pull downs, holding the not selected chip's output enable low and placing that chip's segment output in a non-conducting high impedance state. The output enable of the chip selected by S_2 is either held high or pulsed high by the output of the ID timer. The multiplex timing signals for both ICs come from the same source, allowing the digit enables to function in unison.

Theory of Operation – Oscillator-Divider

The oscillator makes use of two inverters in the CD4060 to form a series resonant crystal oscillator. The 1M Ohm resistor limits the crystal drive voltage and the 4.75 Ohm resistor provides the feedback. The capacitor, C3, gives the circuit phase lead allowing the crystal to operate at series resonance. The output of this oscillator is 15.36 kHz, which is then fed into a 14 stage binary divider. The base frequency of 15.36 kHz is divided by 2^5 for 960 Hz, 2^8 for 60 Hz and 2^{12} for the 3.75 Hz used in the ID timer. Grounding pin 12 allows the oscillator and counter to function continuously. Pin 12 is the reset for the counter and shuts the oscillator off when it is pulled high.

Station ID Timer

The 3.75 Hz square wave from the OSC divider is fed into the input of a CD4040 twelve stage binary divider. The outputs of the 2^7, 2^5, 2^6, and 2^{12} stages are fed into one half of a CD4012 which acts as a coincidence detector. When 2160 pulses have been fed into the CD4040 there will be 1s on the 2^5, 2^6, 2^7, and 2^{12} outputs and zeros at all other outputs. When this happens the output of the first half of the CD4012 will go low, which is then inverted by the second half of the CD4012. A high level on the output of the second half of the CD4012 sets the RS flip flop made up of two of the four gates in a CD4001. The $\bar{Q}$ output of the RS flip flop is now forced low and NORed with the output of the second stage of the CD4040, a .937 Hz square wave. When both

Clock board.

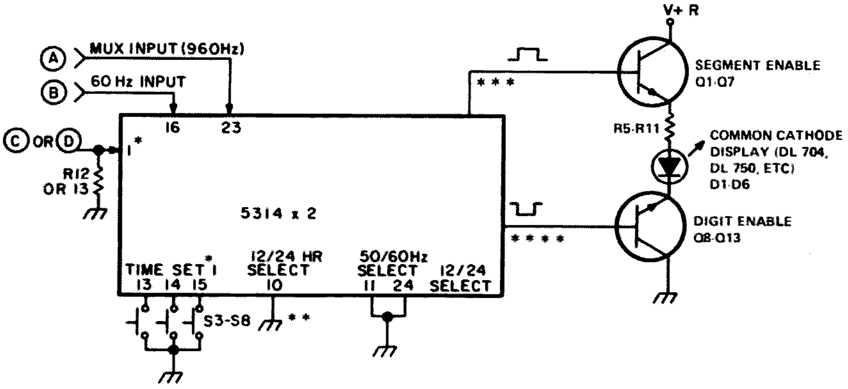

*Fig. 2. Clock chip connections. *These connections are made to each chip separately — all other pins are in parallel. **See text for connection. ***Segment outputs: Pin 3/Segment A, 4/B, 5/C, 6/D, 7/E, 8/F, 9/G. ****Digit outputs: Pin 19/Digit H10, 20/H1, 21/M10, 22/M1, 17/S10, 18/S1.*

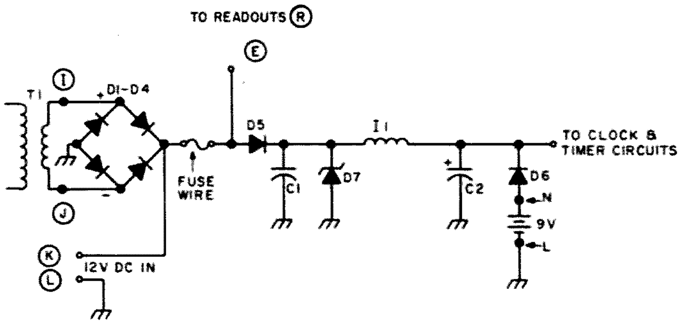

Fig. 3. Power supply.

inputs are low, the output goes high and is then inverted by the remaining quarter of the CD4001, which drives the output enable of the selected clock chip. The result is a .937 Hz blinking in the clock display. Switch S_1 is closed to place a high on the reset input of the RS flip flop and the binary divider, which reset both of them. With the RS flip flop reset, the $\bar{Q}$ output is high, forcing the output of the NOR gate low, which is inverted and holds the selected clock chip output enable high until the cycle is repeated. Placing S_1 in the reset position inhibits the operation of the ID timer. The output of either NOR gate may also be used to trigger an audible circuit of some type.

Power Supply and Filtering

The power supply will take either 9-12 V ac or from 10-14 V dc for power. When neither is present the clock will continue to operate from the 9 V battery but the displays will not light. Diode D5 prevents the standby battery and filter cap C2 from being drained by the readouts. Capacitors C1 and C2, inductor 1, and zener diode D_7 form a filter network for the ac supply and also act as spike and over voltage protection circuit for operation from a 12 V automotive system. Diode D5 also prevents damage in case the power is connected in reverse.

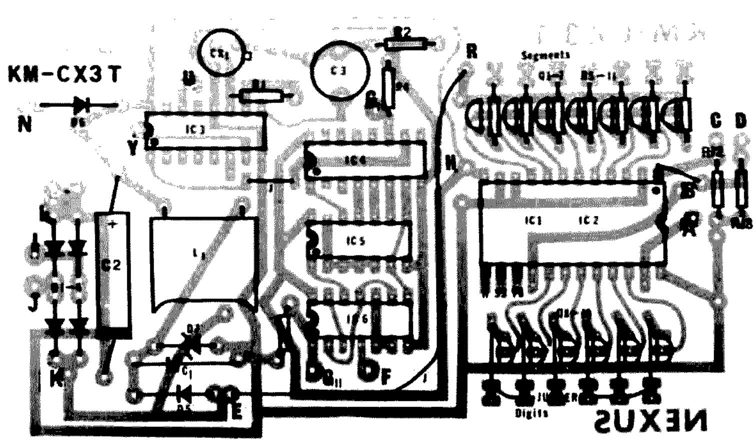

Fig. 4. Clock board (full size).

Construction is relatively straightforward using the printed circuit layouts. The use of two boards allows the clock to be assembled in a minimum of space and with only two jumpers on the clock board. The 17 interconnections between the clock and readout boards also serve as bracing.

The two 5314 clock chips are soldered together pin to pin with the exception of pins 1, 13, 14 and 15. If 12 hour operation is desired on only one chip, then it must be the bottom one. Pin 10 on the top chip is left unattached for 24 hour operation. For either dual 12 or 24 operation, pins 10 on both chips are soldered together. The trace to pin 10 is cut for dual 24 hour operation and left connected for dual 12 hour operation.

Switch S_2 is a single pole double throw, while S_1 is a single pole single throw switch, as are the time setting switches. Power from the ac line comes from a wall plug transformer.

There are only two critical procedures in putting this clock into operation: adjusting the oscillator for 60 Hz and syncing the digit enables of the two clock chips.

The oscillator can be adjusted by any of several methods: The 60 Hz can be beat against the line frequency, a scope set to line triggering can be used, and the frequency adjusted until a stable wave form is obtained, or a frequency counter can be used. If none of the above is available the clock can be run against a known standard and adjusted until it matches.

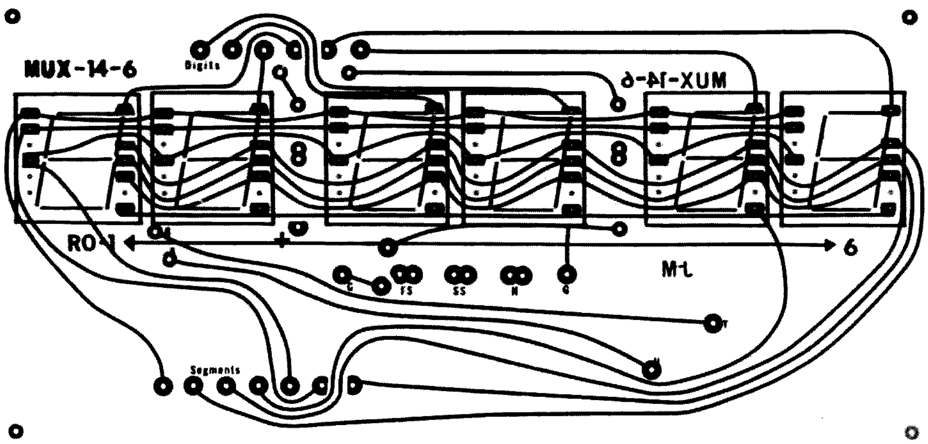

Fig. 5. Readout board (full size).

To synchronize the digit enable lines it is necessary to disconnect all power from the clock including the standby 9 V battery and ground the positive side of C2. The ground on the positive side of C2 is removed and the standby battery is now reconnected, then normal power is applied to the clock. If the display is not correct on both clocks, check the 9 V battery's voltage and replace it if it is not above 8.2 V. Repeat the above procedure again.

At this point the only thing left to check is the 10 minute timer. The actual time is related to the timebase and should be 9.6 minutes. Place the reset switch in the reset position and then back to the timer position. Approximately 10 minutes later the display should start blinking and continue to do so until it is reset. The timer can be disabled by leaving the reset switch in the reset position.

This clock, with its unusual features, should provide you with a timepiece usable in many situations and not subject to the annoying time glitches of its line-based brothers. ■

Parts List

You can beg, borrow, steal, scrounge, or otherwise purloin the following parts. Or save time, trouble, and anxiety pains by purchasing the whole kit and kaboodle from Nexus Trading.

C_1	.1 uF disc cap
C_2	250 uF/25 V electrolytic cap
C_3	3-12 pF ceramic trim cap
CX_1	15.36 kHz crystal
D_1-D_6	1N914 or F125
D_7	15 V/400 mW zener – 1N965B
I_1	680 uH inductor
$IC_{1,2}$	MM5314
IC_3	CD4060
IC_4	CD4040
IC_5	CD4012
IC_6	CD4001
Q_1-Q_7	2N3904
Q_8-Q_{13}	2N3906
R_1	4.7M Ohm ¼ Watt
R_2	1 M Ohm ¼ Watt
$R_{3,4}$	10k Ohm ¼ Watt
R_5-R_{11}	24 Ohm ¼ Watt
R_{12}-R_{13}	2k Ohm ¼ Watt
RO_1-RO_6	DL750 (common cathode)
S_1	SPST switch
S_2	SPDT switch
S_3-S_8	SPST push-button switch

How Accurate Is Your Counter — Really?

But I can't be off frequency by two kHz. I just calibrated my transceiver with my counter which was just set with WWV! This is a comment most often heard among hams operating 2 meter repeater FM. The resulting dialogue indicates there is much misunderstanding among the ranks as to counter frequency accuracy, how a counter should be calibrated and the relationship with one's transmitter output frequency. This article's intention is to shed light upon the multiple ramifications involved in frequency counter calibration.

A most likely starting point, therefore, is the counter time base oscillator. This usually is comprised of a 100 kHz, 1.0 MHz, 5.0 MHz or 10.0 MHz crystal oscillator which may or may not be temperature stabilized with an oven. Typical time base accuracy may be as good as one part in 10,000,000 ($1/10^7$) or less per 24-hour period. If measurements with reasonable repeatable accuracy are expected, the counter will require a minimum warm-up time of one hour with 24 hours' time being recommended. If the counter is being calibrated to factory specifications, a 24-hour period becomes minimum and 3 months is not unheard of.

A laboratory-type crystal reference oscillator used to calibrate the basic time base oscillator in a counter generally goes not reach its stabilized aging rate until a minimum "ON time" of 3 months. This type of standard has its complete oscillator circuit encased in a heavily constructed double oven (an oven within an oven). The typical size of such an oven may be as small as 8" long and 3" in diameter and ovens twice this size are quite common. Such oscillators, when calibrated against WWVB or WWVL, 60 kHz and 20 kHz, respectively, have accuracies as great as one part in one hundred billion ($1/10^{11}$), with $1/10^{10}$ being typical in a metrology laboratory.

A comment quite often heard by lab technicians and radio amateurs contains the following substance: "I have the audible capability to zero beat a signal emanating from the speaker of my receiver." If this is so, then these individuals have indeed been endowed with a very special human ability . . .

The transmitted accuracy of the N.B.S. (National Bureau of Standards) WWV transmission from Boulder, Colorado is $1/10^{10}$, one part in ten billion. Because of signal path distortions, however, the accuracy is degraded by about two orders of magnitude or possibly more. This is known as "The Doppler Shift." The received accuracy is now $1/10^8$ or less. Under the most optimum of receiving conditions and using the best calibration techniques, including an overall time period of 6 weeks for the daily corrections of the crystal oscillator frequency, one could achieve a counter time base accuracy of one part in 10^7 or .00001%.

Reference laboratories on the other hand do not use the WWV transmission

frequencies of 2.5, 5.0, 10.0 or 15.0 MHz because of the limited accuracies available. The low frequency transmissions of WWVB and WWVL are used as they are not subject to the same types of transmission frequency distortions. In addition they can be and are transmitted with much higher accuracies. The transmitter oscillators of WWVB and WWVL do not use crystals. They are controlled by atomic references.

The Cesium Beam standard is an atomic resonant device which provides access to one of Earth's invariant frequencies in accord with the principles of quantum mechanics. It is a true primary reference and requires no other reference for calibration. A cesium atomic beam resonator controlled oscillator is used and is the nation's primary frequency reference. The accuracy of transmission is $1/10^{13}$, one part in ten trillion.

Time and frequency are intangible quantities which can be measured only with respect to some physical quantity. The basic unit of time, the second, is defined as the duration of 9,192,631,770 periods of transition within the cesium atom.

The transmissions of WWVB on 60 kHz are intercepted on receiving equipment of very narrow bandwidth, usually a few Hz wide. The time interval between a local reference oscillator and the frequency of WWVB are compared minute by minute on a strip chart recorder which records the phase differences. The resolution of this comparison is typically 1 us. One part in 10^{10} takes 10^4 sec. to achieve a 1 usec. error (somewhat less than 3 hours).

The transmission of WWVB is coded in the binary coded decimal system. The characters are formed by variations of the carrier in ± 10 dB levels. This presents time-of-year information each minute: the minute, hour, day of the year and the millisecond difference between the broadcast signal and UT2 time.

Universal time, defined as UT time, is the time of day on earth. UT time varies with the variations of the earth's rotation. UT2 time is one of a number of offset times used to correct for seasonal variations in the earth's rotation. These variations are caused by displacement of matter in and over the earth's surface.

Other devices of interest as frequency standards are the Thallium beam, the Ammonia maser, the Hydrogen maser and the Rubidium gas maser. The Rubidium vapor reference standard uses a passive resonator to stabilize a quartz oscillator. It is considered a secondary standard because it must be initially calibrated against a primary standard such as a Cesium Beam. Once adjusted and sealed, the frequency remains superfinely stable and the frequency accuracy is within parts in 12^{12}.

The crystal oscillator, although not the most stable, is still the most economically available to the ham. It is also compact in size and fits easily into the geometry of a compact frequency counter. The frequency counter does have a number of inaccuracies and the crystal reference frequency oscillator is the major one.

The crystal is the time reference base for a divider chain which basically sets up start and stop trigger pulses in the counter. The counter has a number of these, 1 Hz, 10 Hz and 1 kHz being typical. Besides the time base inaccuracy there is also an inherent trigger error which causes a ± 1 count in the readout. The crystal when first turned on has a large drift error. This is overcome by use of an oven and a warm-up period. Thereafter the crystal has an aging rate. This is a constant periodic upward change in frequency with time. All crystals have it. After about 90 days of ON time this rate becomes quite predictable and can be compensated for if the oscillator is equipped with a dial capable of a 1,000 to 1 or better resolution. On the finer laboratory oscillators this vernier readout can be related to time in microseconds.

One does not expect the average ham either to possess the accurate equipment usually found in a metrology laboratory or to apply the techniques necessary for such accuracy. The awareness that such equipment does exist, however, sheds light upon what is required to make accurate calibrations . . .

The average ham is most apt to set up the counter's reference oscillator by zero beating the counter's time base reference oscillator against WWV's high frequency transmissions. This is generally performed aurally after a warm-up period of 1-5 hours. Most often, the inexperienced ham may wind up by beating against the audio of the transmitted signal in which case the crystal will be set to the wrong frequency. WWV usually uses 440 Hz for a period during the hour, then shifts to 600 Hz. If the oscillator has been zero beat to one of these, the error will become apparent when the modulation frequency is changed as the apparent zero beat will have disappeared.

A comment quite often heard by lab technicians and radio amateurs contains the following substance: "I have the audible capability to zero beat a signal emanating from the speaker of my receiver." If this is so, then these individuals have indeed been endowed with a very special human ability, especially when one considers that the human ear cannot hear frequencies below 30 Hz regardless of their amplitude. This also brings into view the necessary unusual hi-fi characteristics required of the receiver's output transformer which probably does not respond below 100 Hz – to say nothing of the speaker response. What one actually is hearing is a difference in the amplitude in the noise frequencies accompanying the signal.

One does not expect the average ham either to possess the accurate equipment usually found in a metrology laboratory or to apply the techniques necessary for such accuracy. The awareness that such equipment does exist, however, sheds light upon what is required to make accurate calibrations. It, therefore, follows that if it is not practical for the amateur to make time interval measurements on the time base generator of a counter and the follow-up corrections in time and frequency, then it also is not reasonable that the amateur expect to have time base frequency accuracy to within $1/10^7$. A more reasonable accuracy level can be expected by following certain ground rules. Allow a 5 hour minimum warm-up time if the equipment uses an oven, 1 hour if not; the time base generator (crystal) should be calibrated by use of a null detector against one of WWV's higher frequency signals, and the intended measurements with the counter be executed as soon

thereafter as practicable. Expected accuracy will be in parts per million or slightly better of the WWV referenced frequency.

A recommended procedure that affords quite good zero beat capability and is readily available to most radio amateurs is as follows:

1. Tune in the WWV frequency to be used. The reception of the signal should be free of fading.

2. The oscillator signal to be calibrated should be coupled so that its amplitude closely equals that of the incoming WWV carrier level.

3. Zero beat aurally as closely as possible, then continue refining the adjustment while observing the receiver "S" meter indication. As zero beat is achieved the "S" meter will reach either a maximum or minimum stabilized indication. This reading will be maximum if both signals are of the same phase relationship or minimum if the phase is out by 180 degrees. It is of little concern which is obtained just so the meter needle has stabilized its position.

If the crystal is of high stability quality and is in an oven, one might want further refinement in the long-term stability capability. In such case it will be required that the crystal oscillator be left on continuously. Further refinements in the zero beat setting will be required each 24 hours, first to correct for the initial phase error setting and then to correct for the crystal aging rate. These further refinements could result in parts in 10^7 accuracy.

Note: For long-term stability a 1.0 MHz or higher crystal is recommended. Zero beat becomes more difficult the higher the WWV referenced frequency. This follows because the resolution of adjustment is reduced and you are working to a finer tolerance.

Assume that the received signal is accurate to 1 part in a million ($\pm 10^{-6}$) and that the adjustment you have just made was set to zero beat with $\pm 10^{-6}$ of the received signal. This will produce a short-term accuracy of $\pm 2/10^6$ Hz. Therefore one can set a 147.00 MHz transceiver frequency to an accuracy of ± 294 Hz depending on which side of the WWV carrier frequency you are zeroed in on. This accuracy will decay with time elapse between the act of calibration and use of the counter.

The above happens to be the hard core truth and should start spinning the mental wheels of those who wonder why they are 2.0 kHz off the center of the repeater bandpass.

For the ham fortunate enough to have the means to perform more accurate measurements, the following is supplied.

1. Counter minimum ON time: 90 days.

2. Compute oscillator drift rate for single measurement spans. The average fractional error of frequency is equal to the fractional time error which is given by:

$$\frac{\Delta f}{f} = \frac{t_2 - t_1}{T}$$

Where

$\frac{\Delta f}{f}$ = Average frequency error.

t_1 = Initial time comparison reading.

t_2 = Final time comparison reading.

T = Elapsed time between readings.

Example (Time comparison reading at 9 am May 1 = 4.64 ms. A reading on 9 am May 4 = 1.70 ms.):

$$\frac{\Delta f}{f} = \frac{4.64\text{ ms} - 1.70\text{ ms}}{3\text{ days}} \times$$

$$\frac{1\text{ day}}{8.64 \times 10^7} = \frac{2.94}{3 \times 9/74 \times 10^7}$$

$$= \frac{29.4}{25.92 \times 10^6} = \frac{1.19}{10^6} \text{ or}$$

$$1.19/10^6$$

That is, the average oscillator error during this period (or assuming a constant frequency drift, the instantaneous error at 9:00 am on May 2) is 1.19 parts per million high. The average frequency of the oscillator during this measurement interval is given by:

$$f\text{ av} = f\text{ nom.} \left(1 + \frac{\Delta f}{f}\right)$$

Where

f av = Average frequency.

f nom. = Normal Oscillator frequency.

$\frac{\Delta f}{f}$ = Average frequency error.

Thus, continuing with the above example and an oscillator with a nominal frequency of 1.0 MHz,

$$f\text{ av} = 10^6 \left(1 + \frac{1.19}{10^6}\right) =$$

$$1{,}000{,}000.119\text{ Hz}$$

Using this method of continuous corrections and recording continuous data one is able to iron out the propagation anomalies of WWV and approach a precision better than 1 part in 10^8. Now with this background behind you — do I hear someone questioning the accuracy of the local repeater frequency??? ■

LETTERS

from page 14

to the 13+ tape, and I found out that the hard way isn't so hard after all. I simply sat down with the faster tape and copied as much of it as I could. At first this wasn't much, and I got very frustrated, but as time went on, I found I was copying several code groups in a row . . . then a solid minute . . . and finally copying it almost solid.

I would like to take this opportunity to publicly thank Jim WB2EDW, who provided an enormous amount of help for me in getting the theory together for the Advanced test. There really are hams around who are willing to help other people with code and theory, and Jim is one of them. (He and his wife, Kathy, also gave me a very good Thanksgiving dinner!) I'd also like to thank Dave WA2CLS for his help.

Finally, I'd like to ask for some help. In 1958 Jim Lev K6DGX administered the Technician test to me (after having shepherded me through the Novice license). I've tried to write to him, but apparently he is no longer at his callbook QTH. Will you please print my address with this, so that if Jim reads it he can contact me, or if anyone else who knows Jim reads it they can either tell him about it or write to me with Jim's QTH? Thanks.

SOCIAL EVENTS

TOWSON MD
APR 4

The Greater Baltimore Hamboree will be held April 4, 1976 at 8 am at the Calvert Hall College, Goucher Blvd. and LaSalle Road, Towson MD 21204. (One mile south of exit 28, Beltway-Interstate 695). Food service, prizes, contests and a giant flea market. 250 tables inside gym. Registration $2. Over 1000 attended last year. Information: Contact Brother Gerald Malseed at school address or call 301-825-4266.

DAYTON OH
APRIL 23

The 7th Annual F.M. BASH will be held on the Friday night of Dayton Hamvention April 23, 1976 at the Dayton Biltmore Towers (hotel) in the downtown area. This new location will accommodate the ever-increasing crowd and will allow a leisurely social evening and a live floor show, featuring television personality Rob Reider (WA8GFF) and his group. Admission is free to all hams and their ladies, and includes free snacks and a C.O.D. bar. A fabulous prize drawing at 11 pm includes a Clegg FM-DX transceiver. Hours are from 9 pm til midnight. Miami Valley F.M. Ass'n., Milt Kohl W8SLY.

GRAND RAPIDS MI
APRIL 24

The 2nd Annual Swap and Shop will be held Saturday, April 24, 1976, 9 am to 5 pm in the auditorium at Woodland Mall on East 28th Street in Grand Rapids, Michigan (corner of M11 and M44). Featured will be ham equipment, electronic parts, monitors and CB. Admission $1.50. For further information write: Grand Rapids REACT Inc., PO Box 2402, Grand Rapids, Michigan 49501.

SULLIVAN IL
APRIL 25

The Moultrie Amateur Radio Klub announces its 15th Annual Hamfest at the American Legion Pavilion in Wyman Park, Sullivan, Illinois on the 25th of April, 1976. Rain or shine, same place as always.

AMBOY IL
APRIL 25

The Rock River Hamfest will be held April 25, 1976, Amboy, Illinois Lee Co. 4-H Center Jct. 30 & 52. Same place as last year. $1 advance, gate $2, write Carl Karlson W9ECF, PO Box 99, Nachusa, Illinois 61057. Rain or shine — indoor or out, camping, large swap shop, food, and many prizes. Short trip west of Chicago. Talk-in 146.94.

CADILLAC MI
MAY 1

The Wexaukee Amateur Radio Association announces their 16th Annual Swap-Shop and Eyeball that will be held May 1st in the National Guard Armory in Cadillac, Michigan, starting at 9 am. This Swap-Shop is open to all radio amateurs, citizens banders, and anyone interested in radio communications. Lunches will be available at noon and there is lots of free parking. Tickets available at the door.

CONTESTS

from page 32

BARC CONTEST

Phone: Starts: 0001 GMT, Saturday, April 24; Ends: 0200 GMT; Sunday, April 25; CW: Starts: 0001 GMT, Saturday, May 8; Ends: 0200 GMT, Sunday, May 9

Any number of transmitters/receivers will be allowed. However, all stations participating must be single operator only. All contestants must operate from their own private residence or property. North America and United Kingdom winners are ineligible for a period of two years, regardless of section won. Use all amateur bands from 80 to 10 meters. No crossband or crossmode contacts will be permitted.

US and Canadian stations may contact UK and VP9 stations only. UK stations may contact US, Canadian, and Bermuda stations only. UK stations are requested to use the official RSGB counties list and abbreviations to avoid confusion.

EXCHANGE:
RS(T) and state, province, UK county or Bermuda parish.

SCORING:
Each completed contact counts 3 points. The multiplier for all stations outside Bermuda is the total number of different VP9 callsigns worked on each band. For Bermuda stations the multiplier is the total number of states, provinces, and UK counties worked on each band. The final score is the sum of all QSO points times the total multiplier.

LOGS:
All dates and times must be in GMT and all contestants must compute their own scores and check logs for duplicate contacts. Include a signed statement that all contest rules and license terms have been complied with. Please print your name, call and address on each page of your log. All logs must be received by the Contest Committee, Radio Society of Bermuda, PO Box 275, Hamilton 5, Bermuda — not later than June 30, 1976.

AWARDS:
A trophy will be awarded to the phone and CW winners in North America and United Kingdom. Round trip air transportation plus one week's accommodation at the Sonesta Beach Hotel will be provided to overseas winners to enable them to receive their awards at the Radio Society of Bermuda's Annual Banquet to be held on October 21, 1976.

HELVETIA 22 CONTEST

Starts: 1500 GMT, Saturday, May 1; Ends: 1700 GMT, Sunday, May 2

Use all bands, 160 to 10 meters, CW to CW or phone to phone; no cross-mode contacts.

EXCHANGE:
RS(T) and 3 figure serial number from 001. Swiss stations will also send the abbreviation of their canton. Abbreviations of the 22 cantons are: AG, AR, BE, BS, FR, GE, GL, GR, LU, NE, NW, SG, SH, SO, SZ, TG, TI, UR, VD, VS, ZG, ZH.

SCORING:
Each contact with a HB station counts 3 points. Each station can be worked once per band, either on CW or phone. The multiplier is the sum of Swiss cantons worked on each band, making a possible multiplier of 22 per band. Your final score will be the sum of QSO points multiplied by the sum of cantons worked on each band.

AWARDS:
Certificates will be given to the highest scorer in each country. USA and Canadian call areas are considered as separate countries.

LOGS:
Logs must be postmarked not later than 30 days after the contest and sent to: TM USKA, Rene Oehninger HB9AHA, 5707 Seengen/AG, Switzerland. Send QSLs for each of the 22 cantons worked on CW or phone for the Helvetia 22 Award to: Blattner Walter HB9ALF, President USKA, via B. Varenna 85, 6604 Locarno, Switzerland.

MASSACHUSETTS BICENTENNIAL QSO PARTY

Starts: 0000 GMT, Saturday, May 1; Ends: 2400 GMT, Sunday, May 2

The contest is sponsored by the South Shore Repeater Association, WR1ACT, of Scituate MA and is endorsed by the Mass. Bicentennial Commission. Any station may be worked once per band; CW and phone are considered separate bands. No crossband or repeater contacts are permitted. MA stations may work other MA stations.

FREQUENCIES.
Phone: 1820, 3960, 7260, 14290, 21390, 28590, 50.110, 146.52. CW: 1810, 3560, 7060, 14060, 21060, 28060. Novice: 3720, 7120, 21120, 28120.

EXCHANGE:
RS(T) and county for MA or ARRL section/country for others.

SCORING:
Each completed QSO counts 2 points. Outside stations multiply total QSO points by total number of different MA counties (max 14) worked. MA stations multiply total QSO points by the number of MA counties plus ARRL sections (not EMASS or WMASS) and DXCC countries worked.

AWARDS:
Distinctive awards will be given along with a certificate for working all MA counties. Separate awards will be given for VHF bands.

ENTRIES:
Mailing deadline is July 15, 1976 and should be sent to: R. J. Doherty W1GDB, RFD =1, 14 Pine Street, Sandwich MA 02563. Include an SASE for results and awards. Decisions of the contest committee are final and logs will become the property of WR1ACT.

NEW PRODUCTS

Lab Science's ECONOTRACE

If you're the kind of person who has to see something to believe it, this new product might be right down your alley. That is, if you test many transistors (and what ham doesn't?). Imagine going through that box of "unknowns" on your bench, and finding out all about them, in just a few minutes. Just plug the device into the "ECONOTRACE," connect three leads to your oscilloscope, and you're ready. One catch: *You* provide the 'scope. Display leakage (ICBO), DC & AC beta, low voltage breakdown, almost anything the big expensive tracers display, according to the manufacturer, Lab Science, PO Box 1972, Boulder CO 80302.

The big advantage is price: the ECONOTRACE sells for $39.50 (plus $1.00 for postage & handling), about a third of the nearest competitor. And it comes completely assembled, ready to operate. One disadvantage: Since it's battery operated, it only tests up to ± 9 volts and ± 90 milliamperes, so it is no good for testing high voltage characteristics. What it is good for is making transistor testing simple and exact (all drives and outputs are calibrated). You can also compare or match devices, just like on the big tracers, with just a flick of a switch. It's also small, 2-7/8 x 4 x 1-7/8 inches, lightweight (10 oz.) and comes complete with its own battery, which lasts for a year. Furthermore, Lab Science offers it on a 30 day, no strings, money-back guarantee, so you too can see it to believe it.

Gray Matters

If any of you SSTV enthusiasts have ever been through setting up a monitor or even a camera, then I'm sure you can appreciate the need for a good accurate and stable tone source. Such a source was described as a construction article in the July 1975, *73 Magazine* on page 98. The item was by Dr. Robert Suding WØLMD, and was just too good to pass up. The ICs totalled up to $7.60 in a recent magazine ad, including the power supply regulator IC – typical of the low cost of TTL-ICs these days.

After I built this amazing little tone source that gives all the tones required for SSTV, and RTTY to boot, I was then tempted to make it even more useful to my needs in building my first monitor. I started building the monitor just for copying the weather satellites, but I have included all the normal SSTV parts in order to set it up and maybe even tune in on all the SSTV these days (on Oscar even!). The following is a small adapter to allow you to use the WØLMD tone source to produce an automatic gray scale for setting up your SSTV projects very accurately (see Fig. 1).

Circuit Changes

The adapter requires you to acquire 5 more ICs at first glance, which from a source like that used above (typical) runs a total of $2.03. Also, you will have to increase the current rating on the transformer used in the original article to 1 Amp. That is the only change to the original power supply. The only change to the rest of the original tone source is to change the control switch marked "Frequency Selector."

Dr. Suding was kind enough to do his frequency changing by only switching around a +5 V source, and therefore I was able to change to automatic switching very easily (see Fig. 2). If you will check the schematic of the adapter in the area of Q1, you will see this is only a simple "electronic switch" with discrete diode or gating. This replaces the original manual switching when the "gray scale pattern" mode of operation is chosen. The original switch called for a single pole (usually a single deck rotary) eleven position switch. Since these are usually twelve position switches anyway, the position 12 can be used for the new manual control switch by getting one with two decks. One deck switches ground around, and the other switches the +5 V, and the two levels control all switching while maintaining the original eleven discrete frequencies.

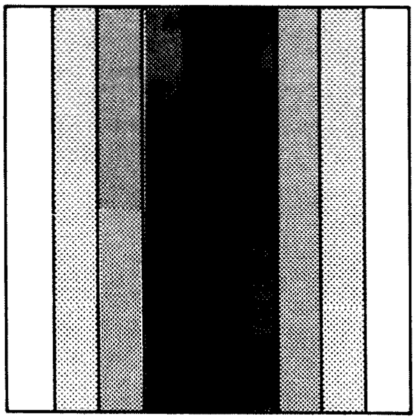

Fig. 1.

Fig. 3 is shown as a slide type switch only for clarity. Obviously, double pole or single pole individual switches could have been used for each position, but this allows the possibility of two on at once which can produce really weird results in this type of device. A twelve position, two deck rotary switch was used in my adapter. If you are building the original and the adapter as an SSTV only generator, some ICs may be deleted as pointed out.

In order to explain my adapter and the original circuit as it applies to my adapter, let me explain the terminology I have used. Since the ICs were not numbered in the original article, I will refer to them as follows:

1. Counters, #1, #2, #3 are the 74193 ICs left to right in the original article Fig. 1.
2. IC "1200," IC "1500," etc., are the gates identified by those numbers near their outputs. (Caution: The frequency found at these points is actually 2X that marked there.)
3. IC "SSTV" is the left 7430 with SSTV frequencies entering it, and IC "RTTY" is the right 7430 with RTTY frequencies entering.
4. The remaining ICs if mentioned are "final gate" for the 7402, and "output divider" for the last 7473.

Circuit Description

First let us decide what ICs can be removed from the original article should you decide to want an SSTV unit only. All 7430 ICs used on RTTY frequencies can go, i.e., IC "1445," IC "2295," IC "2975," and IC

"RTTY." Tie pin 5 to pin 6 on the IC "final gate" 7402. The 7402 has four gates, leaving two not used. IC "1275" and IC "2125" cannot be eliminated as they are part of IC "1500" used in SSTV, but just do not wire them up. This frees up two 3-input NAND gates, to be used differently.

With the extra ICs now eliminated, those retained in part can be wired as follows. First, use part of the 7410 as IC-20 in the adapter using the pins shown in my Fig. 2. Next, the gates I have shown as IC-19 (used as inverters) can be wired up using the extra two gates in the "final gate" 7402. Use the pins shown in Fig. 2 under "OPTION 7402." This has already eliminated two of the ICs I said you would have to buy. One more trick occurs. You can eliminate buying IC-21, a 7473, as well! This and the use of the 7402 unused gates are true whether you go SSTV only or keep the RTTY. This is due to the fact that only half of the 7473 is used in the original article as well. The pin numbers I have given for IC-21 in Fig. 2 allow you to use the other half. That drives the cost of the SSTV only unit down to buying a 7493 and a 7445, and only an additional 7410 for the SSTV/RTTY version ($1.53 or $1.71 respectively). It almost doesn't pay to leave off the adapter!

Now, following the signal through the unit, a 15 Hz square wave or pulse at TTL levels is fed from the monitor, camera or timebase you are using to the 15 Hz input point to IC-17, a 7493 pin 14. A word is required here, as you are probably used to seeing a decade encoder (7490) type IC driving a decade decoder (7445). The 7493 and some gating is used instead to allow very accurate width control to sync width on the gray scale pattern. The normal scan used in SSTV is a 5 ms scan and 1.6 ms sync and retrace period for the 15 Hz standard. This long sync allows for noise "masking" part of sync, etc., and is used much like the automatic line return on RTTY to insure a new line is in step with new information and not skewed. The 15 Hz standard yields a 120 lines times a 6.66 ... ms per line, or 8 second vertical period. With a ten line decoder it is convenient to use a nine or ten vertical stripe pattern, and I chose nine for two reasons. First it allows the generation of a 2300-2100-1900-1700-1500-1700-1900-2100-2300 format, nine stripe white to black to white pattern per Fig. 1. Since sync is "blacker-than-black," you can check your white to black transition response of filters, amps, etc., using the last bar. The use of the white and black bars for setting those levels is obvious and the same as a black or white only generator. Position "0" is left blank, and going to bar #1, white, will show both your overall response to noise in the filters, amps, etc., and another "rather" black to white transition. This is the sneaky reason for using a more than ten position encoder.

As the 15 Hz enters the encoder (counter), the encoder advances the decoder from "0" to the "1" to "9" positions producing the gray scale by gating on the proper tones via the electronic switches. The encoder then goes to position "10." As it leaves "9," that line going high again drives the output of IC-19 pin 6 low. That fall sets the J-K, IC-21, to a high on the Q output, and a low on the not Q pin 8 output that I used. That low turns on Q6 and the 1200 Hz sync tone. The encoder proceeds to positions "11" and "12." The decoder does not recognize any of the 10, 11 and 12 BCD inputs, so all the lines 0-9 stay high. As the encoder tries to go to "13," the BCD (binary really) output of the encoder 7493 is as follows: A = high, B = low, C = high, D = high. The A, C and D lines of the encoder are tied to inputs of a gate, IC-20, and when all are high as in position 13, the output of IC-20 pin 6 goes low. This low is used to pin 6 of IC-21, resetting it and turning off the sync tone after three positions of sync (10-11-12). The same low is sent to IC-19 used as an inverter. The high out from this inverter resets IC-17 encoder, and the entire cycle begins all over.

Using this arrangement, the width control on the monitor is used to set up the "0" noise position on the left edge of the screen, and the "black" of sync on the right edge. Since the minimum hardware was my idea from the start, you may see where as much as one line can be out of sync with the monitor, and this is quite true. The first sync tone puts everything in order, however, and this was not thought to be much of a

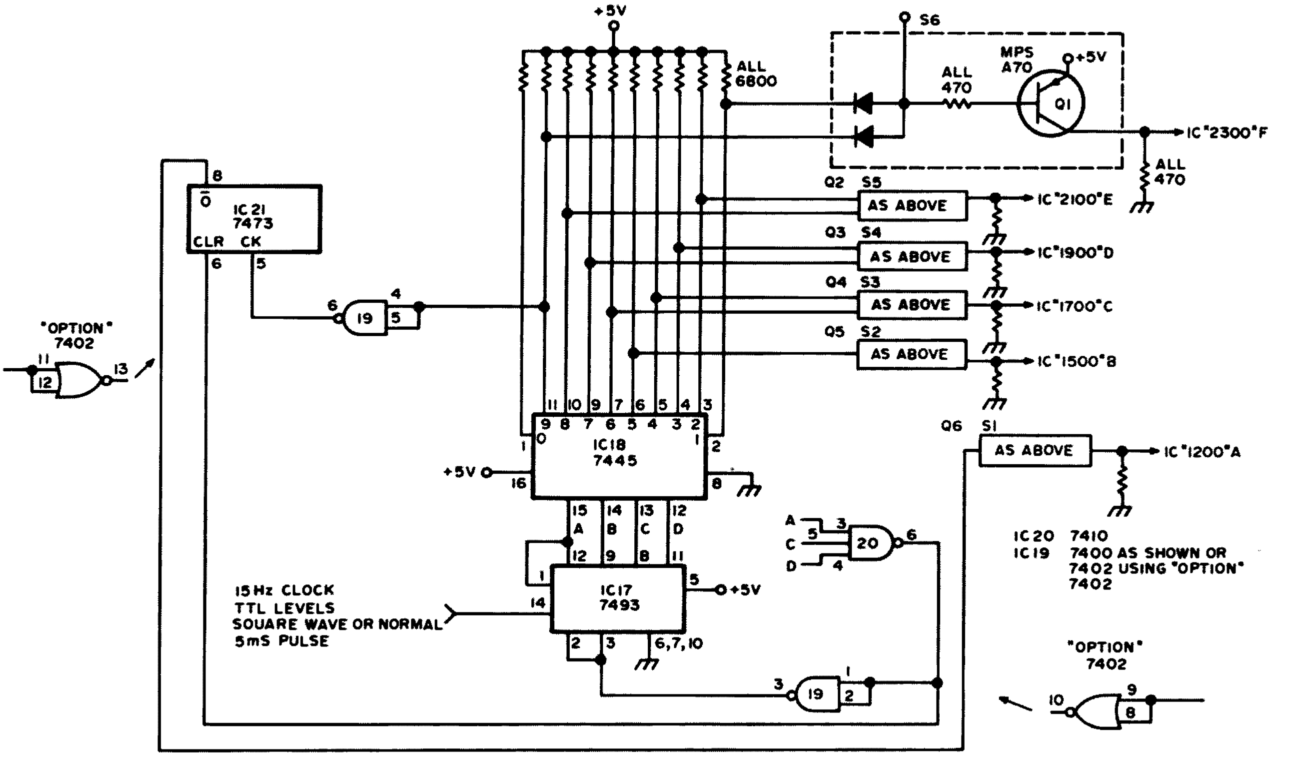

Fig. 2.

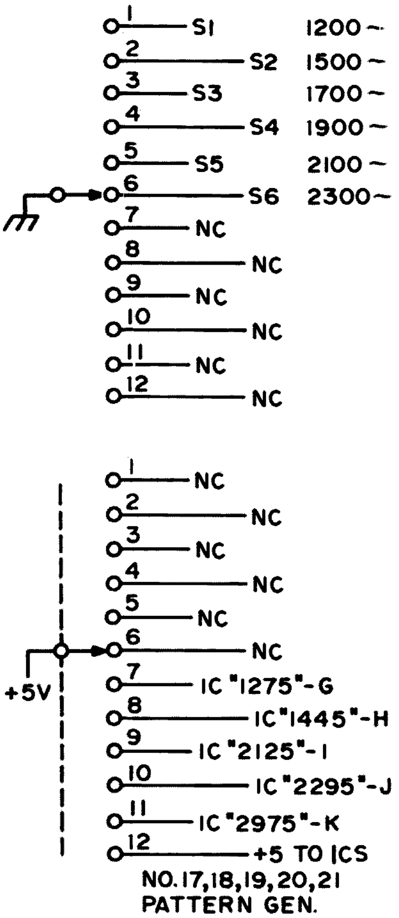

Fig. 3.

problem. In fact, I noticed it following the diagram through, and not in practice to begin with.

Using the adapter as shown, other variations are possible. The most obvious is perhaps to feed the one-per-eight second vertical sync to the 15 Hz input point and you have a white to black to white scan occurring at a one level per field rate, including one of no input. This works if the vertical sync provides your monitor with a return to start and follow new field capability (automatic retrace). Another easy use occurs if you want black/white stripes instead of gray scale. Instead of hooking the diodes up as shown, or by switching them around with a switch, the diodes can be hooked up as all decoder positions odd (1-3-5-7-9) go to electronic switch Q1 (2300 Hz), and all decoder even positions except "0" (2-4-6-8) go to electronic switch Q5 (1500 Hz). Leaving all else the same will give you a wh-blk-wh-blk-wh-blk-wh-blk-wh pattern or alternating white and black stripes. With a bit more tricky gating you can even get a checkerboard out of that one, but more on it later. By feeding the 15 Hz source to a simple divide by ten (7490) and the resulting 1.5 Hz to the 15 Hz input, a horizontal gray scale of sorts results. These latter patterns may not be in sync at first either, of course, for the same reason as the one line problem, but after one sync period all straightens out. Remember to feed the internal horizontal sync to the monitor when doing the vertical tricks, or very strange things happen. Think about it!

As to adapting the adapter, several cute tricks have been tried. I highly recommend you read also the article "Slow Scan TV Test Generator" by Bert Kelley K4EEU in *Ham Radio* (you know – the other mag – hi), July 1973, page 6. This was a TTL device also, and by feeding 2300, 1500 and 1200 Hz in proper timing into the circles lettered E, C and H, and then doing away with all of U1 and the half of U2 used as the sync oscillator, and not using ICs U9, U10 and U11, you can produce vertical, horizontal and checkerboard. The article will provide you with an H and V sync source if you are building a monitor or can't get to yours in a commercial version, and the filter at the end produces a pretty good sine wave in place of the square wave out of the WØLMD device. WØLMD mentions the filtering required, but did not include any, so I have shown the K4EEU filter as my Fig. 4. The 88 mH coils are the familiar telephone toroids and I included Bert's source hoping it is still valid. Several sources exist as I'm sure you are aware. *Don't* run to a transmitter without some filter or you may just regret it. Square waves contain rich hormonics FAR out into the beyond audio range, and TTL square waves seem to strive to get all of them – hi. A word to the wise?

Construction

Construction will vary with the builder as always, and the amount of parts hardly warranted a separate circuit board. I wired mine right into the original article using a particular type of perfboard that has the patterns for ICs and strips out from each pin and then hard wired the interconnects. It really doesn't take long if you use some logic to wire the logic (no pun intended). Wire +V, grounds, all 2048 leads, etc., and use a yellow pencil to mark out what you have done on a copy of the schematic. Construction is not critical, just time-consuming.

For those of you who have not already thought of it, by running three more 74193s from the same crystal source, using another 7410 to decode "1500" just as IC "1500" is wired, and using a divide by 2 (7473) to get a very accurate 1500 Hz just as the article did, but independent from it, you can add two simple divide by ten (7490) ICs and come up with a very accurate 15 Hz source. Another divide by 12 (7492) and divide by ten (7490) IC, just as in the K4EEU article, followed by 5 ms and 30 ms one shots (74121), and you get a very accurate one per eight second vertical sync source. With this you become the neighborhood SSTV "standard." For those of you who like accuracy or as a club project for membership use, this is only $6.52 more in ICs!! I tried it and like it so I'll pass it along, since it does not affect the rest of the operation at all. I'm building all of this into a deluxe monitor with built-in checks, so it comes out pretty cheap (common supply, cabinet, etc.). Use the third lead of the 7410 in the added divider chain to control on/off of this timebase. A +5 V applied to the original terminal "B" turns on and off both horizontal and vertical outputs from this timebase.

An SASE gets all the answers I can provide. Please try to be specific as to what you have/don't have, and where. Please address all questions about the original tone generator to the author. I almost became a K2OAW frequency counter expert (unknown drip under pressure!) over my follow-up "Garnishing a Counter" article, and it is not fair to the original author if I have to quiz him to get an answer, then relay it to you. Comments or further ideas regarding the original or my adapter are, however, very welcome if you send the author a copy for his use, too. We all can learn from these adventures – me, too! It's just not fair for me to get the credit, and sometimes be forced to give advice that may not agree with the author's original intent, such as known limitations, etc.

Have fun using your "gray matter" (source of infinite wisdom located – I'm told – somewhere between the ears) and your "Gray Matter" (scale) source. It sure is handy. ■

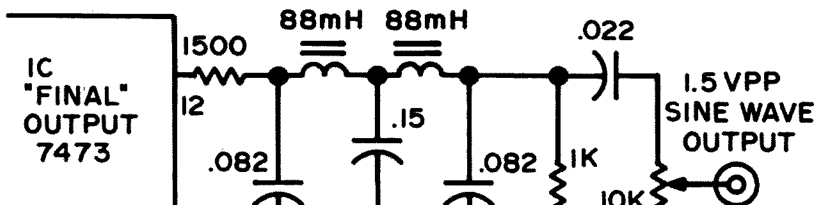

Fig. 4. Toroid source: M. Weinschenker, Box 353, Irwin PA 15642; 5 toroids for $2.00, postpaid.

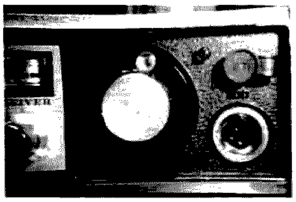
TR-22 Tips

As implied by the title, this article concerns tips directly applicable to the Drake TR-22 2-meter FM transceiver, but many hams (being the innovators that they are) will see value in applying these tips toward other rigs of similar design. Each of these tips has been tried and tested by the author and is workable; furthermore, none will detract from the appearance, operations, or re-sale value of the "stock" TR-22. Sound too good to be true? Please read on and judge for yourself.

The first tip has to do with knowing when your TR-22 is on or off. Maybe this has never been a problem for you...yet. It was for me one day when I accidently left mine on with no antenna connected and squelch fairly tight. The squelch on these radios is excellent, so good in fact, that it is impossible to tell if the rig is on or not unless a signal of sufficient strength is present to break the squelch. The only way you will know that is when the battery pack has run down enough to break the squelch by itself and at that point the batteries are dangerously low. Remember what Peter Stark K2OAW said about nicads in his excellent article in December 74, *73 Magazine*? My TR-22 on-off indicator is a jumbo diffused red LED (light emitting diode) with an appropriate series current limiting resistor. The LED can be run at fairly low light output (which is also low current drain) and still be effective in its purpose. I am using a 390 Ohm, ½ watt resistor in series with the LED and end up with



Light Emitting Diode on front panel.

about 25 mA additional current drain from the batteries. Normal TR-22 receive current drain under squelched conditions is about 45 mA and will peak to 100 mA or so depending upon the setting of the volume control when audio is present. Since the "stock" batteries are 450 MAH units, I felt that the additional 25 mA drawn by the LED was

Broom holder for use as mike clip.

well worth the added protection. By the way, it has been my experience that not all surplus LEDs give out the same amount of light output per current input. You may very well find that you can increase the series resistor (lower the battery drain) by picking and choosing thru several LEDs which I did in the first place.

I located my on-off LED in the upper right-hand open area of the front panel just to the left of the earphone jack, and it looks like "it come outa da box that way." See photo. One 3/16" dia. hole is all that is needed for mounting, but first drill a smaller pilot hole and loosely place masking tape around where the drill will come thru the rear of the panel to catch the filings. Once the LED fits nicely and the hole has been de-burred both sides, a couple of drops of epoxy will hold it in place forever (thank goodness LEDs last that long).

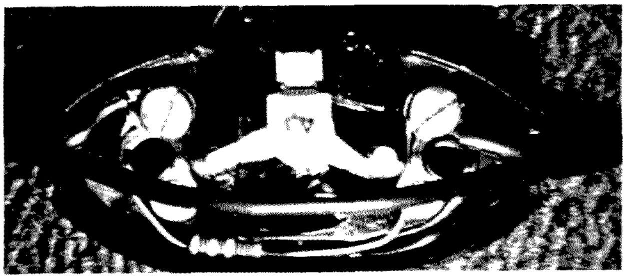
The wiring is easy, only two connections to the TR-22 are needed and one is right next to the LED. The easiest place to pick up ground is from the "sleeve" or outer connection of the earphone jack. The negative (cathode or flatted side of the LED) is connected to this ground thru the 390 Ohm, ½ watt resistor. The positive (anode) of the LED is connected to switched hot 12 VDC; I ran a red wire to point "B" on the receive board which is located at the center rear of that board and is clearly marked. Just wrap the tined end of your wire right around point "B" and solder (no need to remove boards, etc.). That's all there is to it. Go into the nearest closet, raise someone on the local repeater, and tell him at length how great it is to be able to fill out your log by the light of an LED. You will now be able to tell at a glance if your TR-22 is on or off and even if the batteries are

starting to drop off (with experience of course).

Tip number two has to do with adapting a heliflex (rubber ducky) antenna to the TR-22 so that the ducky comes out the top instead of the bottom (ever try to set your TR-22 down on a table with the PL-259 type ducky coming out the bottom?). The first problem here is to not, repeat NOT destroy or in any way modify the existing telescoping whip antenna. Impossible? No, just a little ham ingenuity. I cut the PL-259 connector off of my ducky leaving enough metal at the base to deftly solder on a metal plate cap from an old color TV set which just happens to fit over the conical tip of the existing TR-22 "stock" whip antenna. A piece of heat-shrink tubing over the exposed metal sealed the job from accidental contact with anything else metal. It works like a charm, well, like any rubber ducky works like a charm. Don't fret about the length of telescoped whip inside the metal TR-22 case which now just acts like a piece of transmission line, because it now just acts like a piece of transmission line (at least it's terminated which is more than you can say when using the ducky on the rear connector).

The third tip involves the microphone holder supplied with the TR-22. My TR-22 is the earlier model with the slim pencil mic (which I really like but it can no longer be purchased from Drake). The original mic holder was a plastic cable harness clip which broke instantly (or almost so). I purchased some "C" shaped metal broom holders from the hardware store (you know the type that fasten to the wall and a broom handle can be snapped in), gave one a coat of polyurethane varnish, drilled and tapped a single 10-24 hole in the TR-22 case on the right side midway in both dimensions, and fastened the broom-handle-holder with a minimum length screw. See photo. This holds the pencil mic proudly and indestructibly.

The fourth and final tip will keep your TR-22 batteries up-to-par at all times without overcharging, overheating (remember Pete Stark's article) or shortened life. The key phrase is a "trickle-charge option," once again without destroying re-sale value or digging too deeply into the original well-designed unit. This modification merely involves installing a 15K



Trickle-charge switch on line cord.

Ohm, ½ watt resistor in series with the AC charging cord and an in-line switch to short out said resistor when full charging is desired. Full charging for the TR-22 measures 30 mA on my unit which is safe (less than 1/10 capacity) for 450 MAH batteries, for 14 to 16 hours, but the 15K series resistor in the line cord cuts this to 7 mA which is a good "keep-alive" current to compensate for the nasty self-discharge tendency of ni-cads on stand-by. The in-line switch I used (local hardware store again) is a SNAPIT 10A at 125V unit in which I was able to comfortably mount the resistor right across the switch screws and still pass the line cord (one conductor also attached to the two screws). See photograph. In action, of course, the switch either allows the resistor to be in series with the AC input (switch off) or it shorts out the resistor for full AC input (switch on). Dymo tapes take care of remembering that rather backward type logic (for me anyway). If you are adverse to even modifying the "stock" AC line cord for the TR-22, a standard TV "cheater" cord with the ears slightly trimmed will work in the radio as a charging cord which would be modified in the same manner. Now things don't get much cleaner than that!

In conclusion, it is my hope that these relatively easy modifications will bring you even more enjoyment from an already well-designed, well-constructed and very popular transceiver as they have for this writer. Each of the tips is a "one evening kit" as the Hams at Heath would say, and you will also have the satisfaction of home-brewing something while proving that Wayne was right when he said that Hams are not appliance operators but build what they cannot buy. ■

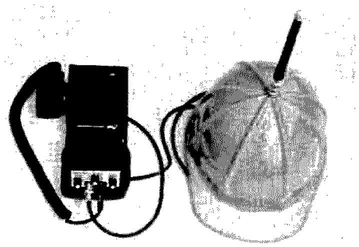
A New Fashion in Hats for the Fun Mode?

Jerry Copeland W8FJA
32540 Stricker Drive
Warren MI 48093

Safety helmets or hard hats are generally associated with the construction industry, but it is very obvious that our pretty model, Mary Hessell, does not need any work in that department. However, if you look at the top of the hat that Mary is wearing, you will notice that she has an antenna up there. If you are at all familiar with 2 Meter FM, you will recognize the common rubber flex antenna, helical whip, rubber duckie, banana, or one of the other names that it is fondly (and sometimes, not so fondly) called.

While this idea of an antenna on a hat is not original, we did do some experimenting and have come up with a pretty efficient performer and we can give you a few examples where you will have to agree that the whole idea is very practical.

Everybody likes a hand-held transceiver. Even if you have a good mobile and base station, there is nothing like a compact rig



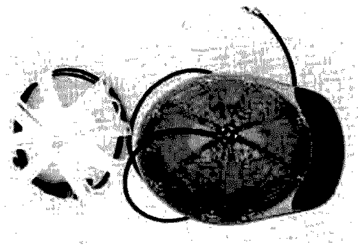
An upside down view of the Clegg HT-146 shows how it looks on the operator's belt.

that you can carry with you around the yard, garage or basement to keep up with what the rest of the gang is doing. If you are going to a swap-and-shop or hamfest, they come in very handy. For Civil Defense, RACES, AREC work, or serving your own community by providing communications for a parade, boat race, or an emergency, they are an invaluable tool.

The best way to carry your rig is on your belt in its own leather case, because it can get quite awkward after a while if you tote it in your hand. This of course makes an external mike the handiest accessory for it that you can have, as you can then operate it while it is still on your belt. Either the built-in speaker will suffice, or you can imitate Walter Cronkite or John Chancellor, and put a button in your ear for private listening. Or, perhaps your rig has a separate speaker-mike combination.

But there is still one big hang up. That rubber duckie antenna working in the vicinity of your navel has little or no efficiency, and your chances of being heard are very poor. The best remedy for the situation is to get it up in the air a little higher as any ham knows from experience. You could carry a six foot step ladder around with you, and if you get one of the new aluminum ones, they are fairly light. But there is an easier way: Mount your antenna on the top of a hard hat.

Safety helmets like this have become a fairly common thing in today's society, as the government agency OSHA is requiring them to be worn any place where head injuries are at all possible. Therefore, we can buy them very readily in most any community. We went to a local safety equipment dealer and found a selection of about five grades, prices and colors ranging from about $2.50 to $6.25 each. The one



The zigzag pattern of the four radials gets lots of wire inside.

that we chose is the more expensive variety and is made of Lexan, which is pretty tough plastic. The better ones have easily adjustable headbands that can be removed and replaced very simply. One of these made the logical option for us because comfort is the number one consideration for our application, and we have some goodies to add to the inside.

The hand-held rig that we are using is a Clegg HT-146, and it has several features that make it well suited to work with the hard hat set-up. The external mike plugs into the top of the unit with a telephone-type plug and is large enough to use easily, but not bulky and cumbersome. When you are not transmitting, it clips to the hanger on the leather case and the coil-cord keeps everything neat and out of the way. The antenna output is to a BNC, and it takes but a second to take off the rubber duckie and connect the coax to the hat, or even to the 5/8ths on the car.

In addition to improving the antenna height for better transmission, we added radials to the inside of the hat to get a good ground plane. After drilling a hole in the top center, we mounted a BNC chassis connector. On the inside, a large thin washer with holes drilled in its edges was placed under the connector before tightening it. This is for the solder connections of the radials and coax braid.

We made several attempts at a pattern for placement of the radials, but finally used the zigzag pattern as shown in the photo. This method provides maximum spacing in keeping the radials away from each other, but still gets the most wire possible inside. We have about 23 inches on each of the four legs, or enough to accommodate a ¼ wave whip on the top of the hat, if you wish.

The radials are permanently attached with epoxy, after holding them in place temporarily with masking tape. We used epoxy on the edges only and used the five minute setting type. The longer timed stuff had a tendency to run down to the bottom of the hat before hardening, because upside down, it is just a big dish.

After soldering the braid and wires together at the base of the connector, we soldered the center conductor, and drilled a hole in the back edge of the helmet for a strain relief clamp to protect the coax line. Then we replaced the liner and the entire project was finished.

It does its job well, though admittedly it is kind of a funny looking thing. You can help this somewhat by adding a little art work if you are handy with a paint brush. Your call letters, handle, and even home QTH would be appropriate to put on the front or side. If you can't paint it, you can buy stick-on letters in any stationary store in dozens of sizes.

Here's another application — if your club or repeater group is called upon very often in your town for traffic control for parades and civic events, you could have all the members make up these hats all in the same color. They would allow you to use your HT's practically hands free, and give you all a uniform type image. Pretty good PR for ham radio.

In the beginning, we only promised you a way of operating your handheld rig from your belt without carrying a step ladder around with you. If enough hams start using something like this, they could catch on until someone comes up with a better idea. But at least you have to admit it's practical!!!! ■

Copper Clad

W.R. Lingenbrink W6HGX
1809 Hill Ave.
Hayward CA 94541

How often have you considered building a new unit to add to the shack and wondered —

Is the cost of the materials worth the effort?

Will it fit on a chassis I have on hand?

How about a cabinet?

What layout will be best?

Well don't think you are alone with these thoughts. Many builders in this day and age consider these factors before starting on a project. This I believe is one of the prime reasons responsible for the "Black Box" routine so readily followed now.

But I have found a use for copper clad board around the shack that puts the challenge back in home building and is a source of never ending delight when new ways are found to use this blessing to the home builders.

The use of copper clad board may not be new to many of the homebrew

generation, what with all of the solid state construction that is going on in the industries throughout the world, and of course the use by the home building group in constructing their projects, but most have been the etched variety of construction.

Have you tried using this same material as you would aluminum, brass or copper sheet when building converters or other types of bread-board construction? I have been truly amazed at the various uses that this type of material can be put to.

It is by far the simplest material to work, as a pair of tin snips can be used quite successfully to cut the material to the desired size without injury to the material. It readily accepts solder and can be cut to form boxes, shields and what not.

One of the principal joys of using this material is the one of short leads and direct ground connections (the ones that generally get us into trouble), along with easy access to the parts.

It is easy to fasten parts to the board. For instance, with a tube socket simply punch the hole in the right location, position the socket for the shortest lead length, then solder the socket tabs to the copper clad. There are no screw holes to position and drill, and no looking for the right size nut and bolt to hold the socket in place.

As for standoffs, tie points or feed thru points, well, the surplus market is still loaded with boards that have those fine teflon bushings by the score. Simply unsolder the connections to them and push them out of the board. As you find a need for them, simply drill the right size hole and insert the type you require in that location.

The use of this material around my shack has given me a new lift on home brewing. Securing the right size chassis for a new idea that I wanted to try was becoming quite a bit of work. It is much easier to use a bit of beat up material that already has lots of holes in it to start with.

A supply of this material can be had for those fortunate enough to live near an electronic manufacturing plant for scrap copper prices. Since not all the units are perfect in manufacturing and quite a bit of this material goes into the saleable scrap, most of these outfits are quite willing to part with this material.

I hope you have as much enjoyment using this method of building as I have, for we can sure use more constructors in our ranks. ■

Bicentennial Seconds

Steve Rich WA1DFL
31 Arlington Ave.
Revere MA 02151

Everyone must have seen those "Bicentennial Minutes" that follow their favorite programs in the evening. Well, after viewing these for quite some time it has become obvious that ham radio's part in history has not been shown and has been well hidden.

After some extensive and exhaustive research, we have uncovered some of ham radio's unheralded facts about the birth of our nation.

In honor of our 200th birthday, 73 is proud to be the first to publish these little known and soon forgotten "Bicentennial Seconds":

Contrary to popular belief, the revolutionary war did not start over "Taxation without representation," but rather the reason being that the colonists believed that America should receive separate country status because it lies more than 200 miles off the coast of England.

History tells us it was Paul Revere that devised the lantern scheme to warn which way the British were coming. The truth is that it was a lad named Morris who, at a Sons of Liberty Repeater Association meeting, thought up the "one if by land, two if by sea" that quickly became known

among the patriots as the Morris Code.

Paul Revere allegedly rode his horse around the countryside to warn of the approaching British. Actually, he never left the comfort of his shack, and used his Handy-talkie on the Minuteman repeater to warn each town and hamlet.

Thomas Jefferson did not only write the Declaration of Independence and the Bill of Rights. He also was largely responsible for the Communications Act of 1774 which established incentive licensing in early America. It called for only two classes of amateur license. The Patriot class included all amateur privileges. The Tory class permitted only five watts input on 27 MHz.

After this didn't work out too well, Thomas Paine was asked by the F.C.C. (First Continental Congress) to write a Docket of Proposed Rulemaking which he entitled, "Common Sense."

Benedict Arnold, in addition to treason against America, also was the first to be convicted of cheating on Field Day. He used ac power rather than portable power.

The Liberty Bell, symbol of Freedom, almost didn't have a home until the Philadelphia Tinkerbelle Repeater Association relinquished their site atop Independence Hall for the Bell.

The Boston Tea Party was supposed to have started over the high taxation of tea. The truth is that the Party started as a friendly hamfest, but when the R.S.G.B. announced a dues increase and a 10 pound charge for their awards program, the Colonists decided to form their own league and a melee ensued.

Patrick Henry's original quote in front of the VA Legislature was, "Give me separate country status or give me death!"

Benjamin Franklin made many contributions to the war effort and in addition made many inventions. One stormy day after Franklin had been flying his kite he informed his fellow OM's that he had invented the electronic key.

General Lafayette almost didn't come to aid the Americans because he was refused reciprocal operating privileges. However, Lafayette changed his mind and decided to come after he was promised he could open a radio store in New York at the conclusion of the war. ■

EDITORIAL BY WAYNE GREEN

MISSING ADVERTISERS

Many readers have been writing in to ask about specific manufacturers whose ads have not been running in *73*. Since *73* has more ads than any other ham magazine . . . and since the *73* policy is to refuse ads to unreliable firms . . . firms which are advertising in other ham magazines even though the publishers know they are unreliable . . . readers ask, to make sure, whether such and such a firm has been refused ads in *73*.

Several readers have asked about Eimac recently. Eimac advertises in the other three ham magazines, but not in *73*. As far as we know the reason for this is that Eimac is trying to put pressure on *73* to run non-controversial editorials. No one in the industry is going to force *73* to run or not to run anything, including editorials, and we at *73* think that this attempt to use economic power to influence the press is a serious matter. Read the editorials in the other ham magazines and decide for yourself how successful Eimac has been . . . not a controversy in a carload.

We at *73* think that thought-provoking controversy is healthy for amateur radio . . . and we know with a certainty that it is healthy for *73*. *73* is published for the readers and will continue to be responsive to the readers, not manufacturers who try to buy what they think should be in the magazines. Ads should be run for the purpose of selling products, not for forcing the manufacturer's views on the editor.

Eimac is big enough and independent enough of the ham market so they can do very well with or without ham magazine advertising. This puts them in a good position to throw weight around . . . weight which few magazine publishers can afford to ignore.

About the only difference to the average *73* reader is that each issue of the magazine is just a few pages thinner . . . perhaps there is one less article as a result of the Eimac boycott.

Another missing advertiser, of late, has been EBC. We at *73* felt that the EBC rig did not meet the published specs and held up further ads until the situation was cleared up. Recent reports are that EBC had cleared up the problems with the rig so as soon as this can be verified by a test of a new rig with all the latest mods, EBC may be back in *73* again.

Missing ads like that are expensive both for *73* and for the advertiser, so ads are not held up frivolously.

MORE HAMFESTS?

If local hamfests were better promoted to bring in CBers and other prospective hams instead of just being geared for the entertainment of those already licensed, we might be able to bootstrap more chaps into our interesting hobby.

Hamfests can be run for a profit, you know. Those interested in finding out details on how to make big money out of hamfests should get in touch with Leonard Norman . . . an ex-ham (the FCC took away his ticket) . . . who has been running 'em for years in Las Vegas. Write to him at his convention headquarters in Boulder City, Nevada or, if there is any problem, get his Boulder City office address from *Ham Radio Magazine* in Greenville NH . . . they are very close to Norman.

Commercialism can go too far, of course, so you have to be careful about this. If you charge for manufacturer booth space, for admission, for technical talks, dinners, cocktail parties, and everything, you may find interest dropping. You may be able to get away with having a manufacturer pay for a cocktail party . . . and then

ROCKY MOUNTAIN HIGHS

Aspen was a blast – all that we expected and then some! We all regretted leaving there, that's for sure. I skied solidly for six days, starting Sunday, January 11, on the four 11,000-foot mountains – Aspen, Aspen Highlands, Buttermilk and Snowmass – and found them all superb. Aspen village is located at the foot of Aspen Mountain and Aspen Highlands, and Snowmass was about 12 miles away.

Chuck WA1KPS, Wayne W2NSD, and Pete WB9FLW from Illinois took lessons on Buttermilk most of the week and I skied with Eric WA1HON from Lincoln, Mass. We did our damndest to ski everywhere, but were lucky just to hit every lift on the mountain for one ride during the day. That's how many lifts there were and how big the mountains were! Most of the trails were very wide, sweeping down the mountainsides. Sugarloaf in Maine has, in my opinion, the only trails in the Northeast at all comparable and it's less than half the size of, say, Snowmass. The weather was clear almost every day we were there, with the exception of Monday when we had snow flurries. The scenery was simply majestic with snowcovered mountains and valleys visible in every direction. The temperature during the day ran from 15 or 20 degrees to about 30 to 40 degrees by the end of the week. Because of the altitudes (Aspen village is 8000 feet – almost 2000 feet higher than New England's Mount Washington), we'd get winded easily; I came up puffing just from bending down to buckle my boots.

We all carried 2 meter FM walkies and had fun chatting together on "52 direct" between mountains while riding up on the chair lifts. No repeaters yet in Aspen – wait until *next* time! Chuck brought along an Atlas SSB transceiver and Dentron tuner and we had a batch of 75m QSOs using an end-fed "long wire" hung on the hotel balcony one dark night.

Our hotel was very nice as expected – very convenient, located between the two chair lifts at the foot of Aspen Mountain, about a block from the nearest lift and a block from the bus stop from where the free bus shuttles ran to all the other mountains. After skiing each day, we jumped into the hotel's heated pool for awhile. Boy, that hot water was great for the aching muscles after 6-7 hours of skiing! Fun to float on your back and look up at the stars or snowflakes, whatever. Then, into the sauna to sweat for a bit in its 230 degree temperature. We all got together for supper every night, which was a "peak" experience of the day, since, although the town has a population of 7000 to 8000, it has 80 restaurants and nightclubs and we went to a different gourmet restaurant each night. Supper would last a couple of hours, then maybe we'd look in on a nightspot briefly, and off to bed.

The restaurant prices were a bit high – as was everything else in town – usually supper cost around 15 bucks apiece. But the food and service were superb.

We did encounter several unpleasant situations, unfortunately. We had a beautiful flight out to Denver from Boston on Saturday, January 10th. Chuck, Eric and I met Wayne W2NSD, fresh in from the SAROC hamfest, at the Denver airport. That's where our troubles began. Seems that the little airline which was to fly us the 200 miles out to Aspen had sold at least two tickets for every available seat. Things were totally screwed up when we arrived with a lot of people standing around getting unhappier by the moment and the airline people acting unpleasant about the whole thing. Wayne finally managed to get on a plane and leave for Aspen, but not the rest of us. After we'd been there about 4 hours, we said the hell with it, cancelled our tickets, had a heckuva time reclaiming our bags and skis, rented a car and set out about 7 pm to drive to Aspen, in spite of warnings about icy roads and snow-blocked mountain passes. Fortunately, the weather was fine, and with good moonlight, the visibility was excellent. Immediately west of Denver, which is 5000 feet, you climb into the mountains and we drove over a couple of 11,000-foot passes, a fantastic drive. Passed the Loveland ski area, the top of which seems to be above timberline, then through Vail which is a mass of condominiums tucked in a narrow, deep valley, and some other big ski areas I don't remember the names of. Finally, about midnight, we left the main highway west, and drove the last 40 miles or so south to Aspen, arriving about 1 am. We finally found the hotel after plowing through masses of party-goers (that's Aspen *every* night!) and off to bed. Up early and off to Buttermilk for a super first day of skiing in foot-deep powder and balmy weather. When we returned to the hotel, Chuck and Wayne's room had been robbed: tape recorder, still and movie cameras, airline tickets, and a 2m walkie – in all about $2000 worth. Three days later, Pete WB9FLW from Illinois, who had joined our group, had his room robbed. There were several other thefts from our hotel during the week. Chuck caught a bad cold and was unable to ski for the last two days. On a few occasions, we were overcharged for meals, but our sharp eyes caught the errors.

It was a great vacation and my skiing here in New England can now be described as only second-best. You can't believe how much fun it is to run those big beautiful trails out there – even the moguls are bigger – can you visualize Cannon Mountain's Zoomer or Polly's Folly trails half to three-quarters of a mile long or even steeper? Or skiing a trail even longer without seeing one mogul? Or being scared stiff while riding a chair lift up an 11000-foot high narrow ridge – just wide enough for chair lift and ski trail underneath and looking down sheer cliffs on either side? I was in terror on that one, located at the top of Aspen Highlands. Rode it a second time to see if I was still scared – I was... Or the beauty of the snow plume blowing off the 14,000 footer up the valley between Buttermilk and the Highlands. Or the memory of stopping high up on Aspen (Ajax) Mountain late in the afternoon and looking down at the village a couple of thousand feet below. Or the sheer fun of running the open snow fields near the summit of Snowmass, called the "Big Burn," due to a fire which cleared most of the trees from the area years ago. Still an occasional tree there to dodge in the half-mile wide ski "trail." One can get spoiled fast with this kind of a mountain.

So, inevitably, it all came to an end. On the 17th, we caught the shuttle bus to the airport near the foot of Buttermilk, *packed* into the little twin-engined Otter aircraft – big enough for 19 passengers, and climbed out over the Aspen valley en route to Denver, about an hour away. No cabin pressurization – my fingers turned blue, Wayne appeared to be slumped over up forward. Scenery below was superb. Then, big DC-10 airbus to Boston – 2 seats wide on either side plus 4 seats in the middle. Landed a little after 6 local time and found it bitter cold and windy in Boston. Home about 8, vacation over. I'd like to give some credit where it is due – first to Wayne and Chuck for the whole idea last summer, to Rocky Mountain Airways who provided us the inspiration to drive from Denver to Aspen (I wonder whatever happened to the 47 anxious folks ahead of us in the Rocky Mountain queue at Denver), to the Continental Inn at Aspen where the accommodations were excellent, but had unsolicited room serivce (the burglars), and to amateur radio itself which got me going on the best vacation imaginable for this ham skier.

Sandy Cole W1PVF/1

HI YOURSELF

Just received your new *73* format. I don't like it. Looks like mid-winter Sears sale catalog. Hi.

Jack Kulish K7YNY
Stanford MT

WHAT SERVICE!

I would like to tell you how pleased I am with one of your advertisers. I mailed two separate orders at different times to James Electronics. Both orders were mailed on Sunday and received back in my mail box the following Saturday. What service! Also I received 100% of what was ordered. No back orders, no substitutions, and no oversights. You can't believe how easy this makes building a project. Others are still waiting to receive their B/Os or missent parts.

Harry R. Clement
Des Moines IA

I recently placed orders with three of the advertisers in the pages of *73:* S. D. Sales, James Electronics, and A P Products, Inc.

All three of the orders were received complete, exactly as ordered, within 10 days of my mailing of the orders!!! This is fantastic!!! S. D. Sales even included a free package of LEDs, which is unheard of when dealing with the large suppliers.

I'm sure I am not alone in saying THANK YOU to you and the advertising staff of *73* for making it possible for these relatively small companies to become known to your readers. I think that it is unfortunate for amateur radio that the January 1976 issue of *QST* contained only one advertisement from a small parts supplier which, incidentally, was not one of the three listed above.

Please continue with your work at *73* in the same vein as you have been. We may not always agree with your viewpoint, but at least you do make your readers aware that there occasionally *can be* justifiable, sensible and rational alternatives to the ARRL position on various matters. Thanks for the originality of *73*!

Louis A. Hodges W9LMI
Chester IL

Thanks, Louis — I do like to hear about good experiences with advertisers. I also want to hear immediately about any bad experiences with our or other magazine advertisers. I have been known to raise hell over things like that. 73 loses a lot of money every month by refusing to accept ads from firms running ads in QST, HR and CQ . . . I need to know who the good guys are and who the bad guys are . . . and I want to know when they change their spots. Re my editorials . . . I get a big laugh out of a few manufacturers who won't advertise in 73 because they think this will force me to run QST-type editorials . . . that's dumb. I write my stuff to get the juices running and whether I believe what I write or not is irrelevant. I want readers to think and have some fun. Oh, a few get up tight . . . but you know, oddly enough, I get virtually no letters to the editor which I could use instead of my editorials to get readers thinking . . . pity, for I'd rather be out skiing than writing. Without controversial ideas, 73 would be just like the other ham magazines . . . and you wouldn't want that — Wayne.

KEEPING PACE

K8YYP's request for heart pacer information reminded me that others having or contemplating a pacer installation might benefit from a cassette tape made by VE7QQ, another pacer recipient.

Sadly, Ken VE7QQ died from other causes. However, I will make a copy of his interesting recording, at cost, for those interested.

Yes, I contacted K8YYP.

Huntsville AL

EXCEPTIONAL OAKLAND

In light of recent editorial comments about repeater operations, we feel that certain points should be brought to light. In our area, we have a repeater (of which we are both control ops) which *does* provide a source of intelligent discussion and which *does* provide first rate emergency service. We are speaking of WR2ABN (10/70) in Oakland, N.J.

We have both had the privilege to monitor and to participate in serious discussions of music (both classical and jazz), astronomy, astrology, religion and philosophy on this repeater in the evening hours, and have found these discussions most stimulating.

Likewise, the Oakland 10/70 machine regularly handles more emergency traffic in a week than any of the repeaters listed in that other magazine do in a month, a fact which we intend to publicize further. In addition, in every instance of bad driving conditions in the metro North Jersey/New York City area which has occurred in the past year, WR2ABN has been used almost continually throughout the period as a clearinghouse for road and weather information, with formal net control and monitoring of the National Weather Service reports and local police channels to provide greater assistance. Travelers in and through our area know that, if they should need assistance or encounter an emergency during the normal operating hours of the repeater, they need only put out a call for help and someone will come right back to them.

In contrast, local Citizens Band is almost impossible as far as transmitting a readable message through the din is concerned. The total discourtesy and lack of concern for any sort of operating standards is the rule here on CB. In much monitoring, we and others have yet to hear an emergency report on CB in this area, even on Channel 9, because that too is usually clogged with multiple QSOs all interfering with one another.

In short, we do not really wish to disagree with your premises entirely, although we have both encountered other machines elsewhere which are also most helpful, but rather to point out that, in our area, WR2ABN is an exception to the sentiments expressed in recent issues.

QUICK AND CHEAP

Suggestions from a pre-Novice — Include projects on a regular basis that can be constructed cheaply and would help a Novice to get on the air. Examples: T-R switches, CW transmitters and receivers, quick and cheap antennas, etc.

If we are to attract new people to amateur radio we need attractive projects that can be built quickly, from readily available parts, and give the builder an immediate sense of participation in radio. Construction projects for Novices are all too often built and designed by amateurs with years of "junk box" materials and experience at hand. Novices, on the other hand, have no used parts, no familiar sources of supply, and little or no schematic and construction experience.

The 5 band transmitter on pg. 125 of the Nov/Dec issue is a typical example. This transmitter is just what I'm looking for. However, the article does not include a complete parts list, has no wiring diagram that shows component placement, and makes no attempt to teach a Novice. The project could have included construction details, theory, suggestions for coupling with a receiver/antenna (T-R switch), and a single source that sold all parts.

The scope project on pg. 74 is much more complete, as it includes many of the details mentioned for a Novice project. Yet this project is written for far more advanced hams. Quick and cheap projects seem to get short and sweet space in magazines these days, yet if a beginner can't get started, he will move on to another field of interest — one that will gratify his needs and interest.

William Cook
Alpena MI

ROCKING HAM

I want to tell you how much that 13+ wpm code tape has really helped me. Believe me, I've only spent a total of less than 7 hours, and my speed is up to about 15 wpm!

I am 20 years old (soon to be 21). I took my Novice test in Nov. 1974 and got the license in Jan. 1975. Then 3 months later I was out of work for 3½ weeks because my place of work had to close for remodeling. So I "boned up" on the theory (even though I knew some radio theory) and the code. Then in April, 1975 (note the 3 months later!), I took the General and Advanced on the same day and passed! I also used your tape at school in spite of the other kids giving me that weird look.

I also plan to go for my Extra class soon. I also agree that if you want that ham ticket, *earn it!* Don't sit around lazily and hope someone else will give it to you!

I now work 2 meters as well as HF, and would you know? These guys on 2 meters are beautiful and I love them! I've received a lot of help from them too, which I dearly appreciate!

I'm also planning to get up a rock group and call it "Larry WA4MJQ, And His Ancient of Days." Who knows? This may indirectly expose amateur radio to the public.

After reading some articles in *73*, I also want to note that I've also had trouble with Trigger Electronics. However, I did get my money back through the intervention of the Postal Inspection Service.

I really like your magazine!

Larry S. Lawhorn WA4MJQ
Richmond VA

COMPUTERE(A)SE?

Keep the microcomputer articles coming . . .

Robert Brubaker K3UPK
Lebanon PA

Thank you for stimulating our interest in computers.

What we need now is articles which tell us for what purpose we may use a computer.

What will a computer do for us in the home, the workshop, and the ham shack?

Tell us. It will help us to know the applications, and that would in turn be good for the industry.

Harry D. Minshew W6ZOW
Hemet CA

Right! Well, I can think of a lot of things I want to do with a computer, such as get a list of the times and antenna bearings for accessing Oscar 7 . . . playing Star Trek, Twenty-One, Lunar Landing and many other games . . . keeping an index and list of all the recipes I like . . . an index to all of the ham articles of possible interest to me such as RTTY, SSTV, uP, FM . . . an index to my record and tape collections . . . a list of all the repeaters in the world . . . a list of all the DX stations I've contacted and the details about them, QSLs . . . my checking account . . . generation of SSTV pictures and art . . . generation of art on my color TV set . . . RTTY generation and contacts over the air using Baudot, ASCII or Morse Code . . . accessing other computers via Oscar 7 . . . mailing list for some clubs I belong to . . . editing letters and articles which said computer then can print out . . . key word sorting RTTY short wave news broadcasts for anything concerning amateur radio . . . checking for any calls via any repeaters within range automatically . . .

things like that. With two or three terminals most computers can do several tasks at once . . . okay?
– Wayne.

I will not forgive you for bringing a new interest into my life, just when I had decided that I had more than enough projects to keep me busy. A friend of mine, Dave K5WNV/7, has an Altair 8800 with 16K memory, CRT terminal and TTY I/O. Friday he brought home from Albuquerque one of their floppy disk units. Since I don't want to get in that deep and his unit is idle a good deal of the time, we have started a ham radio-computer project. We live 25 miles apart and he is going to send me the video output from his I/O port on 439.25 MHz and I am going to access the machine with an ASCII keyboard modulating a 147 MHz FM transmitter. At least that's the plan. We've applied to the FCC to use ASCII on two meters. Enough for now – I'll get Dave to write it up when we are up and running.

Rod Hallen WA7NEV
Tombstone AZ

Sure like the new format, but am wondering about all the highly technical computer and digital articles you feature. I'm an Extra and schooled as an E.E., but this stuff is so far beyond me – only thing I understand is the title. I'm certainly for progress, but it seems many of these articles are way beyond the normal reader you may have. I take all four ham pubs – and like yours the best – but honestly it's leaving a good part of us in a cloud of dust. Respectfully submitted,

Lon C. Brickley W4AFS
Pompano Beach FL

If you live in the metropolitan New Orleans area and are interested in computers, you are invited to join our group. Whether your interest is hardware, software, applications, or just general interest, we welcome your input. For further details please write or call me.

Emile Alline, Jr. WA5WUJ
1119 Pennsylvania Ave.
Slidell LA 70458
504-641-2360

P.S. Keep up the good work – especially in translating "computerese."

ENTERPRISE

Just finished building the Starfleet Communicator (February, 1976). Nice toy; the girls love it! However, I did have some trouble getting the little unit going, and so offer the following suggestions to those who have built, or will build, this device.

First off, use only a fresh, heavy-duty 9 volt battery when checking out the unit. Secondly, the voltage on pin 5 of IC1 (7493) should be fairly close to 5 volts. When I first tried the unit, the voltage on this pin was less than 4.5 volts, and the communicator would not function. The problem could have been due simply to the characteristics of the various devices I used. The LEDs were from James Electronics (Model XC526), while the UJT was one contained in a package of 4 which was purchased at Radio Shack (Part Number 276-111). Regardless, I lowered the 100 Ohm resistor in the 5 volt supply line to about 50 Ohms so as to obtain the proper operating voltage.

At this point, it was necessary to lower the 82 Ohm resistor in the gating line (pin 11 of IC1) to 39 Ohms, and to bypass pin 14 of IC1 with 0.3 uF (for noise suppression) before the unit would function.

Some other hints . . . I built my unit in the case of an old transistor radio. This provided the case, a speaker, and a battery compartment all in one step. Further, not wanting to bother with the flip-up top, I simply mounted an SPST switch on the side of the case which is used to activate the communicator. Finally, I used ElectroCraft Model 35-414 push-button switches (miniature, momentary switches) for S2 and S3.

As I said, the unit is working and the girls love it (ages 6 and 7). Further, I learned quite a bit in the process of building it. Hopefully, with the above info, others will have an easier time getting their communicators going.

Ted Cohen W4UMF
Alexandria VA

P.S. James Electronics is fantastic!!! Ordered some parts by mail on Saturday, and had them by noon, the following Wednesday!

YL 73 73!

Recently Jim Ricks W9TO, inventor of the world-famous keyer, sent his young lady to pick up his auto tags. Completely by chance, his new plates read: YL 73 73 !

Gene Brizendine W4ATE
Huntsville AL

BAD APPEARANCE

I recently learned a valuable lesson about automobile security. While parked in a hotel lot in Milwaukee, my car was broken into, and my broadcast radio, along with a good part of the dash, was stolen. This was not a tape machine, and an examination of nearby cars turned up several with better, more easily removable units. However, my car did have the bottom half of an HF antenna on the bumper. The police seemed to think that the thief was looking for CB units, and being unable to see through the frosted windows, broke in, and then took what was there. I guess the moral is avoid even the appearance of a rig in the car.

Alan P. Biddle WB9SQB
Madison WI

TYPING

I really enjoy your magazine. I'm planning to get my Novice license pretty soon.D o you think you could have a few how- to-do-it articles for the guy who is not too experienced. T hanks. So much for my typing.

Tom Rosicka
Springfield OH

THE QUEST FOR THE HOLY PR

Please eyeball the enclosed PR spot I landed in my local newspaper. I'm proud of it and you should be too, because WA4BDW's story in the Jan. *73* inspired its beginnings. You know this guy had a lot of nerve with his item #2, "Land a feature story in a local newspaper," bit. But since the CBers get it done now and then I thought what the hell. So I wrote Bob Iverson (author of article enclosed) a letter and invited him over to the house to see what I had going. I baited the invite with things like Oscar, ATV and the like, and used the basic premise (per FCC R&R) that hams are around to provide emergency communications and enhance international goodwill. Note how that got in the first paragraph.

This story appeared on Sunday, Jan 18th in the Danville *Commercial News*, which is owned by a big outfit called the Gannett News Service. The local paper circulates better than 75,000 with Danville, Illinois the hometown of about 41,000 people.

You might be interested in knowing that I took about an hour to prepare for the reporter's interview by painstakingly bookmarking articles (especially ones with photos) from *73* and *QST* to back up everything in the story. My presentation took about 25 minutes, including questions from Iverson and the photo. It was topped off with a short QSO with WN4BSL in Owensboro, Ky. for effect. I might add that my presentation was very general and not at all technical, touching on a variety of things which I thought non-hamming, non-technical readers might like. Again, the basic premise was to make aware the existence of us in the event of a large scale disaster. Detente is in too, so hence the goodwill.

A local ham whom I've never met called to tell me that the story created a lot of interest on the 2 meter net and congratulations were offered on behalf of himself and all the locals. A very nice gesture, I thought, since this guy is a General and is into slow scan in a big way, which would have been nice for the mug shot.

At my place of full-time work, I was treated as somewhat of a man-of-the-hour and greeted by a programmer on the staff with "Who the hell do you know at the paper?" No one. At my place of part-time work, country FM station WIAI, the manager was very pleased and intended to send the owner of the station and the building a copy of it. He lives out of town, in fact out of the county. This, despite the fact that WIAI is not mentioned in the article. I jock there on weekends, just in case you ever buzz around here, Wayne. 50,000 Watts 99.1 and good country music. What more could you want???

Anyway, that's my effort toward PR, and you and WA4BDW should be congratulated for the inspiration. But most of all, Bob Iverson of the *Commercial News* should be honored for his excellent writing and comprehension. After all, the reporters have to write these things and they really decide how well it's going to go over.

You know, I've read many articles telling us we need PR, but nothing about *how* to PR. Maybe you could help by telling us how to prepare feature article presentations, or HOW to set up booths at local CB jamborees or HOW to give demonstrations for school science classes. Some of us don't know how to organize our time or talk or any damn thing. I made my presentation without any idea how it would turn out. Lucked out I guess.

Well, so much for all this. Hope you enjoyed the clipping and thanks for listening. Also like the new mag format. It's about time.

Ted Osborn WN9PIQ
Danville IL

P.S. Also, tell Mary she did a fine job with my Reader Service requests for this month.

INFLATION

In reference to the January 76 issue of *73 Magazine*. The article "County Hunting" by W2SDU quotes the price of Directory of Post Offices available from Government Printing Office under stock No. 3900-00242 at $4.25.

Have just received the copy I ordered and find the correct price is now $5.05 – the price quoted now being obsolete.

Earl Stacy K7BD
Selah WA

IN ENGLISH, PLEASE

In reference to your article "Stereo – A New Type of CW Filter," in the March issue, it doesn't take much imagination for RTTYers like myself to stick the Mark and Space scope monitoring audio outputs of the teletype converter into an inexpensive "hi-fi" stereo amplifier and tune for equal left and right separation of the FSK signal. Using stereo headphones gives you a pretty broad left-to-right audio "picture" of the signal so that centering the FSK around the crossover point is fast and very accurate. Note that QSBing of the Mark and Space frequencies does not effect the tuning sense you have as you bring the signal into proper position. This simple method of tuning FSK gives you a great sense of security, because

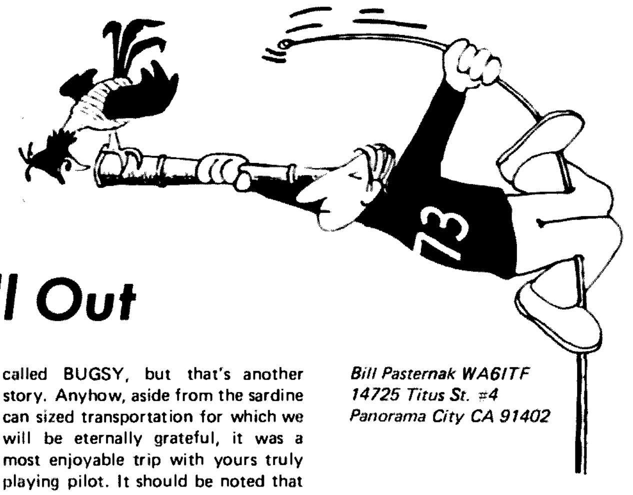
Looking West



A Dark Horse Will Out

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

Ever have a run of luck when nothing goes right? You know, when it seems like the gods have things stacked up against you. That's just the way 1976 began. Actually, it began in early December when some low creature decided that he needed my Icom IC-2F (serial #4893 if you happen to run across it) more than I did and went to the trouble of purloining said radio from under the dash of our '63 Cadillac. I said trouble, since it not being my nature to trust mounting brackets and such, I had drilled three holes through the top case cover and mounted the radio directly to the dash in as inconspicuous a spot as I could find. I guess the spot was just not inconspicuous enough and scratch one IC-2F.

On New Year's Eve I remember telling Sharon that '76 would be better than '75; it had to be. Was old ITF ever wrong! On New Year's Day afternoon, the oil pump in our '71 Torino let go and took the engine with it. Oh, the idiot light did come on . . . after the car had chugged and grinded its way to a stop. My thanks to the many amateurs from both WR6ABB and WR6ABE that came to our aid and got us down to sea level from atop Muhulland Drive, and a special thanks to George WA6MQM who is currently hard at work putting all the pieces together once more.

This morning, though, was the clincher. Though on its last legs, the old Cad was still running and I had to renew my driver's license. The Department of Motor Vehicles office is about a mile from here, so bright and early this am, I drove over and obtained my renewal. I was going to make a stop at one of my parts suppliers when I noted some steam from under the hood. Well, this car has had a water leak since I bought it, but it is always wise to check. Being almost at my house, I drove there and parked. Lucky I did, since it seems that the water pump and the radiator had given up at about the same time. Have you any idea what it's like to be sans wheels in Los Angeles? You cannot even get to the corner unless you have a car, and here I sit in our living room — the auto score, 2 down, 0 to go! Oh well! If '75 was bad, so far '76 could be classified as a disaster!

The Torino going down for repair came at the wrong time — just a week prior to SAROC. We had about given up hope of getting there when Rick WA6VSK offered us a lift across the Mojave to the fun city of Las Vegas. Three people and all the necessary luggage packed tightly into the confines of Rick's '72 VW bug. Reminds me a bit of a trip cross country in '70 with Lou K2VMR in his VW lovingly called BUGSY, but that's another story. Anyhow, aside from the sardine can sized transportation for which we will be eternally grateful, it was a most enjoyable trip with yours truly playing pilot. It should be noted that this area is enjoying (and I use that term loosely due to the fire hazard now present) a very warm and dry winter season. In fact as I write this, it is Feb. 2, the temperature is almost 80 degrees and kids are out swimming in the apartment house pool. While slightly cooler, the weather across the desert and in Las Vegas was similar. Beautiful.

Since I described SAROC last year in some detail, I will not bore you again with the same story. Suffice it to say that SAROC is unlike any other amateur radio convention in that the city of Las Vegas rather than the convention itself is the top attraction. Las Vegas is a world in itself and one of my favorite vacation spots. I really think that Vegas should adopt the motto "Have Fun and Enjoy" since that's what the city is really all about. Even the "losers" often smile.

Our first stop upon arriving at the Sahara was of course the registration desk where we found out that our pre-paid reservations for that hotel had been transferred to the Thunderbird since the Sahara was full up. I was set to "blow a gut" when I remembered that the Mt. Wilson Repeater Association was to be hosting a "Hospitality Suite." A quick call on Rick's HT brought forth the melodious tones of Bill Orenstein KH6IAF/7. Bill advised me to "cool my head" and come up to room 4022, better known as the "Mt. Wilson Repeater Association Friendship Suite." This was the "Dark Horse" of which I spoke in the column header. While the theme of most hospitality suites at conventions is one of "party-party," this one was different. It was kept low key — a place to get away from the festivities and regroup one's head. You were greeted by the state flag of Hawaii as you walked through the door, with soft music mostly of Hawaiian origin playing in the background. It was just a tranquil spot in the middle of the confusion that is any convention.

The room was made possible through the cooperative efforts of the MWRA, Worldradio News and Midnite Radio. If one must single out individuals who were responsible for the overwhelming success of this

Capt. Dick McKay K6VEP (left) and Gary Wood WA6DTX (right) enjoy lunch with John Johnston K3BNS, head of the FCC's Amateur and Citizens Division.

Wayne and Sherry visit with Lon and Sybil Albright of SANDRA in SAROC FM Hospitality Suite.

Bill Orenstein KH6IAF/7 (left) and John Marin WA2IEU show Wayne WR6ALD/7 in MWRA Hospitality Suite.

Squeak's "drinkie-talkie" — never saw that option in a Motorola catalog!

special kind of convention hospitality center, there are two people that then deserve special mention. First, Bill Orenstein KH6IAF, this time /7, for conceiving the idea, doing the legwork and giving up just about all his time at SAROC to play host. However, all this work would have been for naught if it were not for the fine cooperation given the MWRA and Bill by the Sahara itself. This cooperation came in the form of Mr. Billy Snyder, Executive Host and Assistant to the President of the Hotel Sahara. Working together, the MWRA and the Sahara had one of the nicest "let's get away from the convention for a while" spots to be found. Heck, it was the only such spot aside from our room at the hotel. Yes, we finally did get one by the way, though we had to wait a while. I guess patience will out.

Now, as if all the above were not enough, there was more. The MWRA is a user support organization for the Mt. Wilson based WR6ABE repeater. Being one of the busiest repeaters in the nation, it was conceivable that a goodly number of its members would be attending SAROC. For this reason, it was decided that a portable repeater might just be in order. John Barreiro WA6HQL made available a modified Heathkit HW202 which was further modified, converted and completed as a repeater by Kirk Nemzer WB6EGR. It was set up "split-site" with the receiver and its antenna on the top floor of the hotel and the transmit site on the balcony of the MWRA hospitality room. How does one go about tying the two ends together so that a system such as this can function? The MWRA electronics crew made use of the "house" phone system, of course. Now the frosting on the cake. It is always good to have an ID of some type on a repeater and a special events repeater such as this naturally requires a special ID. Again thanks to Bill KH6IAF/7, the voice of Mr. Jerry Lewis could be heard on 146.40 stating, "Fooled ya! This is not WR6ABE Los Angeles; this is WR6ALD/7 at the Sahara Hotel, Las Vegas, just the other side of the Colorado River thingie. Ha hahhhh." To read it is not to hear it, and one must have heard it to have really appreciated it. A lot of us did. Thanks, Jerry.

This was not the only portable system to show up. The Palisades ARC of Culver City was there as usual with its portable .01/.61 system, that thanks to Neil McKie WA6KLA, performed at its high level of efficiency. One must remember that PARC was in the forefront of supplying their membership with portable systems of this sort for occasions such as this. Someone else brought a .93/.33 system, I understand, but that never really went into full time operation.

UHF was well represented, with a number of remote owners bringing their goodies along for use by their people. One system, a full-blown remote, came in all the way from New Jersey along with its owners John Marin WA2IEU and his brother Tom WA2IKB. But, this year it was the MWRA that really stole the show when it came to both hospitality and portable repeaters, and for this "Looking West" must give them the "Hats Off Salute" this year. They deserve it.

Surprises, you bet your sweet bippie. I guess that the biggest one to yours truly was the guy who walked into the FM Hospitality Suite Friday evening. None other than *73*'s very own Mr. Green himself. I was just standing there talking with someone when it was suggested by someone else that I turn around. Surprise! More like shock. Wayne, why don't you warn me when you are going to pull these surprise visits!?

Anyhow, not long thereafter, in walks Bill KH6IAF and in short order, Wayne finds himself shanghaied up to the 40th floor to view the MWRA suite and the WR6ALD/7 repeater. As you can see from the photo, I get the feeling that our "leader" was somewhat impressed. Unfortunately, it was to be a brief visit that we would have that evening, but in the time we had to talk I was able to catch up with what has been happening back East. Wayne was the smarter of the two; after our get-together he went "73s" for the evening. Me, I was up most of the night talking with this one and that one. How I ever made it to the FM forum and the FCC forum the next day I will never know. Thank heavens that someone developed the cassette tape recorder.

At this point I should really get into a discussion of what Johnny Johnston talked about at the FCC forum, and until about 48 hours ago that would have been exactly what I would have done. However, something very important has transpired within the last two days that deserves very special attention now. Therefore, we will continue with our coverage of SAROC and the FCC forum held there next month. Right now it is again "Giving Credit Where Credit is Due" time, and it is with a heck of a lot of pride that "Looking West" salutes the accomplishments of a great many Southern California amateurs who have spent the last few days working hand in hand with the Guatemalan Consul General to Los Angeles in relief efforts to that earthquake-ravaged nation.

For time reference, this portion of "LW" is being written on the morning of February 9; it is exactly a week since I began to write this and the blue skies and warm temperatures of a week ago have since been replaced by an unending torrent of rain. Winter — the winter we have waited for has finally arrived. It's 1:11 am and about an hour ago I finally returned home from Los Angeles International Airport where I had spent the last 8 or 10 hours. As a writer it is strange to find yourself a part of your own story, but in this case it is what happened. I had gone to LAX to photograph and report on a rather unique and highly successful communication effort and within minutes found myself taking an active part in what was happening.

Problem: How do you get communication in and out of a country that has had most of its communication with the rest of the world severed by natural disaster? I guess you know the answer, since the answer is what we, the amateur radio community, are all about. Such was the situation in regard to Guatemala. Less than a week ago, that nation suffered a major earthquake that according to the latest network newscasts has taken 15,000 lives and effectively cut Guatemala off from the rest of the world save amateur radio. Though a number of area amateurs had been providing communication to Guatemala for the past few days, there had been no organized effort set up. The local consulate had been swamped with requests by local citizens as to the whereabouts of friends and relatives in Guatemala and the load was increasing as hours wore on. It was obvious that some fully organized effort was needed, one that would insure that a maximum number of health and welfare requests were handled while at the same time taking some of the load off the local consulate so that they could work on other important relief efforts. Such was the problem that Doug K4SWJ/6 posed to me on the telephone some 48 hours ago. Doug, like myself, is a member of the Palisades Amateur Radio Club of Culver City, and both of us felt that it was a definite obligation for PARC to take an active role in this project on a large scale basis. Saturday morning, February 7th, Doug called PARC President Dan Deckert WA6FQC and plans were formulated. The local

CONTESTS

Editor:
Robert Baker WA1SCX
34 White Pine Drive
Littleton MA 01460

CORRECTION

The Delta QSO Party will be held September 25-27 – not April 24-25, as listed in our April issue.

COMMON MARKET CONTEST

CW
Saturday, April 3
0600 to 2400 GMT
Phone
Sunday, April 4
0600 to 2400 GMT

Use appropriate mode on all amateur bands, 80 to 10 meters. Please keep the lower 10 kHz of the CW bands and the upper 25 kHz of phone bands free according to IARU recommendations. Entry classes consist of: single operator – all band, low band (80 and 40), high band (20, 15 and 10); multi-operator – single transmitter, all band only.

EXCHANGE:
RS(T) and QSO number starting from 001.

SCORING:
Common Market stations score 1 point for QSOs with other Common Market stations and 5 points for QSOs with others: multiply total QSO points by the number of DXCC countries on each band. Non-Common Market stations score 5 points for each Common Market QSO and 1 point for any other QSOs; multiply total QSO points by the number of Common Market countries worked on each band.

AWARDS:
Certificates to the highest scoring station in each country, in each entry class, on each mode. Trophies awarded to the highest scoring single operator in the Common Market on each mode and to the highest scoring single operator outside of the Common Market on each mode.

LOGS:
All entries must be mailed no later than April 30th to: Jacky Luyten, Ave. Max 134-b1, 1040 Brussels, BELGIUM. Please use the common log form style and do not forget a summary sheet.

Common Market Countries: Belgium, Denmark, France, W. Germany, Great Britain, Ireland, Italy, Luxemburg, Netherlands.

TRIPLE LETTER QSO PARTY

Starts: 1700 GMT Saturday,
April 24
Ends: 2000 GMT Sunday,
April 25

The contest is sponsored by the University of Missouri-Rolla ARC, WØEEE and is open to all amateurs. Any contact between amateurs is valid on any band 160 to 2 meters, using any mode. No repeater QSOs or cross-mode contacts will be allowed. Each station may be worked once per band per mode.

FREQUENCIES:
3950, 7215, 14290, 21375, 28600. CW – 45 kHz up from band edge.

EXCHANGE:
RS(T) and consecutive QSO number.

SCORING:
Each QSO counts for one point, with one extra point added for each repeated letter in the suffix of the station worked call. An extra point is also added for 2 letter suffix calls. (Examples: WB4GOP = 1 pt, WA7UMU = 2 pts, WØEEE = 3 pts, WØGS = 2 pts.) Total score is the total QSO points times the number of states, countries and provinces on each band, times the total number of triple letter stations on each band. Example scoring: 500 QSO pts x 67 (states, countries and provinces) x 24 triple letter stations = 814,000 pts total.

ENTRIES:
Send logs along with the usual data and declaration before May 20th to: Ward Silver WBØGQP, 590 Fieldstone, Ballwin MO 63011.

GEORGIA QSO PARTY

Starts: 2000 GMT, Saturday,
May 8
Ends: 0200 GMT, Monday
May 10

The 15th annual Georgia QSO Party is sponsored by the Columbus Amateur Radio Club. There are no time or power restrictions and contacts may be made once on phone and once on CW on each band with each station.

FREQUENCIES:
CW – 1810, 3590, 7060, 14060, 21060, 28060. SSB – 3900, 3975, 7245, 14290, 21360, 28600. Novices – 3718, 7125, 21110, 28110. Try 160m at 0300 GMT, try 10m on the hour, and 15m on the half hour during daylight hours.

EXCHANGE:
QSO Number, RS(T), and QTH – county for GA stations; state, province, or country for others. GA to GA contacts are permitted.

SCORING:
Each completed QSO counts 2 points. GA stations multiply total QSO points by number of different states and Canadian provinces worked. DX stations may be worked by GA stations for QSO points only; they do not count as multipliers. Out-of-state stations will use the number of GA counties (max. 159) worked for their multiplier.

AWARDS:
Certificates to the highest scoring station in each state, province, country, and GA county. Also to the highest scoring GA and non-GA Novice. Second and third place awards will be made in sections where additional recognition warrants. A plaque will be presented to the single operator and multi-operator GA stations submitting the highest score in each category. Plaques will also be awarded to the highest scoring out-of-state entry and to the highest scoring GA portable and mobile stations operating outside their home county.

LOGS & ENTRIES:
Your logs should show: date and time in GMT, station worked, exchange sent and received, band used, type emission, and multipliers claimed. Check lists will be appreciated. Include a signed declaration that all contest rules and operating regulations were observed and mail your entry to CARC, c/o John T. Laney K4BAI, Post Office Box 421, Columbus GA 31902. Entries should be postmarked no later than June 7, 1976. Please include a large SASE for a copy of the results.

VERMONT QSO PARTY

Starts: 2100 GMT Saturday,
May 8
Ends: 0100 GMT Monday,
May 10

The 1976 Vermont QSO Party is sponsored by the Central Vermont Amateur Radio Club in Montpelier VT. The same station may be worked once on each band and mode. Mobile stations may be worked in each new county (consider each new county they enter as a new station).

FREQUENCIES:
Try CW on odd hours and phone on even hours (GMT). 3560, 7060, 14060, 21060, 28160, 50260, 144-144.5, 3909, 7265, 14290, 21375, 28600, 50360, 145.8, 3932, 7290, 14325.

EXCHANGE:
QSO number, RS(T), and county for VT stations, or ARRL section for others.

SCORING:
VT stations score one point per contact and multiply by the number of ARRL sections and countries worked. All others score 3 points per VT station worked and multiply total by the number of VT counties worked on each band. Maximum of 14 counties per band.

AWARDS:
Trophies will be awarded to the highest scoring station outside of VT and to the highest scoring single operator station in VT. In addition, certificates will be awarded to the highest scoring station in each ARRL section and country with a minimum of 3 different QSOs. Certificates also will go to the 2nd, 3rd and 4th highest

CALENDAR

Apr 24 - 25	Triple Letter QSO Party
May 1 - 2*	MASS Bicentennial QSO Party
May 1 - 2*	Helvetia 22 Contest (H22)

* = described in last issue

scoring stations in VT. A special certificate will be awarded multi-operator and mobile stations operating in VT. QSO Party contacts can be credited toward the Worked Vermont (W-VT) Award issued to stations working 13 out of VT's 14 counties.

LOGS:

In order to be eligible for awards, logs or facsimiles together with an SASE must be mailed no later than June 15th to: Peter Kragh W1AYK, 170 Summit Avenue, Ramsey NJ 07446.

All band/mode activity is urgently needed from the counties of Bennington, Caledonia, Essex, Grand Isle and Orleans. Anyone interested in portable or mobile operation is asked to contact W1AYK or the CVARC.

RESULTS

RESULTS OF THE 1975 CW COUNTY HUNTERS CONTEST

High score – fixed	WB4OGW	433,048 points (new record)
High score – portable	WAØKXJ/6	220,869
High score – mobile	WA5KQD/m	438,658 (new record)
Composite mobile score	KØDEO	292,358

There were a total of 301 counties activated by portable/mobile stations during the contest, while the total number of counties worked by contest stations was 613. The highest number of different counties worked by any single entry was 407 counties (WB4OGW). The winners in each state and category are as follows:

STATE	CALL	SCORE (pts)	
CONN	WA1KMP	48,723	fixed
ME	W1APU	4,750	fixed
MASS	W1AQE	65,860	fixed

YL INTERNATIONAL SSBers QSO PARTY

Starts: 1901 GMT Friday, May 14

Ends: 1900 GMT Sunday, May 16

All bands will be used on CW and phone and the same station may be contacted on different bands for contact points but not for country multiplier. Use country multiplier only one time. The QSO Party is in three categories: DX/WK teams, YL/OM teams, single operator. Non-members are welcome to participate and QSO party logs will be accepted for SSBers awards in lieu of QSLs.

EXCHANGE:

Name, RS(T), SSBers number (send no number if non-member), country, state, partner's call (if no partner leave blank).

FREQUENCIES:

CW: 3565, 7085, 14070, 21070. Phone: 3873, 7273, 14333, 21373, 28673.

Some European stations cannot work in the US phone band on 80 or 40 meters; when calling them please announce that you will tune around 3775 or 7090.

SCORING:

Contact with SSBer member on same continent = 2 pts phone, 4 pts CW. Contact with SSBer member on different continent = 4 pts phone, 8 pts CW. Non-member contacts = 1 point phone, 2 pts CW. Multipliers are number of different DXCC countries (must be YL-ISSB members), US states, DX/WK teams, and YL/OM teams regardless of bands. Final score is total QSO points times total multiplier.

AWARDS:

Plaques will be awarded to the highest individual score, DX/WK teams, and YL/OM teams, as well as to the highest score single operator. Certificates to first and second place in country and state. No certificate to plaque winners.

CATEGORIES:

DX/WK team – Each team consists of a DX and W/K SSB member. The team score is the sum of both partners. Score will be determined when both logs are received. If only one log is received it will be scored as a single operator entry. All stations entering the DX/WK team category should immediately send a request to W7EOI. You may choose your own partner or, if you have no choice, W7EOI will assign one to you as requests are received. All requests must be in writing (for records) except DX stations who may make their requests through system controls. One week preceding the QSO Party, teams requesting to be recorded may do so through system controls during daily operation. No team assignments may be made after the party begins.

YL/OM team – Each team consists of one YL SSB member and one OM SSB member who are related: husband/wife, father/daughter, etc. Operation must be from the same QTH, using the same rig with his/her own call.

LOGS:

All logs must show date and time in GMT, RS(T), SSBer number, partner's call, mode and period of rest time. Each entry must operate a minimum of 6 hours with a minimum of 6 hours rest period for each 24 hours of contest period. Logs should be postmarked on or before June 30th and be received on or before July 15th. Send logs to: Lyle Coleman W7EOI, 412 - 19th Street SW, Great Falls MT 59404.

For free QSO Party entry form (no logs), send an SASE to: Robert Baker WA1SCX, 34 White Pine Dr., Littleton MA 01460.

MICHIGAN QSO PARTY

Starts: 1800 GMT Saturday, May 15

Ends: 0200 GMT Monday, May 17

The QSO Party will be sponsored by the Oak Park Amateur Radio Club. Phone and CW are separate contests, but a station may enter logs for both modes. MICH stations may work MICH counties for multipliers. A station may be contacted once per band on each mode. Portable or mobile stations may be counted as new contacts when they change counties.

FREQUENCIES:

CW – 1810, 3540, 3725, 7035, 7123, 14035, 21035, 21125, 28035, 28125. 1600 - 1900 GMT try phone: 1815, 3905, 7280, 14280, 21380, 28580. Try 15 meters on the hour and 10 meters on the half hour. On VHF, try: 50.125 and 145.025.

EXCHANGE:

RS(T), QSO #, QTH – county for MICH stations, state or country for others.

SCORING:

MULTIPLIERS ARE COUNTED ONLY ONCE. MICH stations score one point per QSO times the total number of states, countries, and MICH counties worked. Non-MICH stations score QSO points as: 1 point for each W/KWA/WB8 MICH QSO, 5 points for each WN8 and special events station QSO. Total score is sum QSO points times the number of MICH counties worked (83 max.). VHF only entries score same as above except multipliers per VHF band are added together for total multipliers.

AWARDS:

Only single operator stations qualify. Trophies will be awarded to MICH stations for: high CW, high phone, high aggregate club score. Plaques will go to high Novice, high VHF only entry. Certificates to high CW and phone in each MICH county. For non-MICH stations, trophies for high

CW and phone. Certificates for high CW and phone in each state and country. Members of the Michigan Week QSO Party Committee are not eligible for individual awards.

ENTRIES:

A summary sheet is requested showing the scoring and other pertinent information, name and address in BLOCK LETTERS, and a signed declaration that all rules and regulations have been observed. MICH stations include name of club for combined club score. Party contacts do not count toward the Michigan Achievement Award unless one fact about MICH is communicated. Decisions of the Contest Committee are final. Results will be final on July 31, 1976 and will be mailed to all entries. Mailing deadline is June 18th and should be addressed to: Mark Shaw WA8EDC, 3810 Woodman, Troy MI 48084.

WORLD TELECOMMUNICATIONS DAY CONTEST

Phone
Starts: 0000 GMT Saturday, May 15
Ends: 2400 GMT Saturday, May 15
CW
Starts: 0000 GMT Saturday, May 22
Ends: 2400 GMT Saturday, May 22

This is the seventh running of this annual contest sponsored by the Brazilian Ministry of Communications and is open to all amateurs. Categories include: single operator multi-band, or fixed/maritime mobile stations operating from ITT Zones 76 to 90. Use all amateur bands from 160 to 10 meters. Contacts with the same station are allowed on different bands, but ITU zones are valid only once as a multiplier regardless of bands.

EXCHANGE:

RS(T) plus ITU zone number. (Please remember that the ITU zone numbers are different from those shown on the ARRL and CQ maps and charts.)

QSO POINTS:

Contacts with stations in the same country = Ø points. Contacts with stations in different country same ITU zone = 1 on 10 to 40 meters, 2 on 80 and 160 meters. In another ITU zone, same continent: 10 to 20 meters = 2 points, 40 meters = 3 points, 80 and 160 meters = 4 points. Another ITU zone, another continent: 10 to 20 meters = 3 points, 40 meters = 5 points, 80 and 160 meters = 6 points.

SCORING:

Final score equals sum of QSO points times total number of different ITU zones. ITU zones only count once regardless of bands.

LOGS:

Use separate logs for each mode. Logs should indicate in this order: GMT time, worked station, message sent/rcvd, band, continent, zone (and multipliers), QSO points. Logs should be postmarked before June 30th and sent to: Ministerio das Communicacoes, Dentel, Brasilia, D. F. Brazil.

AWARDS:

The sum of points earned by the top five contestants of each country on each mode will be used as "Country Points" to determine the winner of the ITU trophy. A winner country for three consecutive years or five interspaced years will keep the ITU trophy permanently. Gold, silver and bronze medals will be awarded to the three top world scorers on each mode. Diplomas will go to the three top scorers in each country, on each mode. Countries with a high number of logs will be granted diplomas to the first three in each call area.

Clubs and associations will be included in a special multi-operator multi-band category and will not be counted for country points. A silver plate will be awarded to the top world winners on each mode. Diplomas will be awarded to the three top winners in each country on each mode. Logs must be signed by all participants from each club or association.

WISCONSIN STATE QSO PARTY

Starts: 0000 GMT Saturday, May 22
Ends: 2400 GMT Sunday, May 23

This is the annual QSO Party sponsored by the Neenah-Menasha Amateur Club. Phone and CW are considered separate bands. The same station may be worked on each band and mode. Wisconsin stations may work other Wisconsin stations for QSO and multiplier credit.

FREQUENCIES:

1810, 3550, 3735, 3900, 7050, 7135, 7235, 14050, 14280, 21050, 21135, 21300, 28050, 28600, 50-50.5, 144-146.

EXCHANGE:

RS(T) and QTH — Wisconsin stations will send their county for QTH, others send ARRL section or country.

SCORING:

US and VE contacts count one point while DX contacts count 3 points for Wisc stations. All others score one point per Wisc contact. Wisc stations are to multiply the total QSO points by the number of ARRL sections contacted (74 max.); KP4, KH6, KL7 and KZ5 count both as 3 point QSOs and as section multipliers. All non-Wisc stations should multiply the number of Wisc QSOs by the number of Wisc counties worked (72 max.).

AWARDS:

Certificates will be awarded to the high scoring fixed, portable, mobile, Novice, and VHF stations in Wisc as well as each ARRL section and each DX country.

ENTRIES:

A summary sheet and station log are requested. Indicate each multiplier the first time worked. Logs must be received no later than June 15 (DX logs by July 1). All entries should be addressed to: Neenah-Menasha Amateur Radio Club, Inc., Mark Michel W9PJT, 700 Kinzie Court, Menasha WI 54952.

MICHIGAN ACHIEVEMENT AWARD

The Governor of Mich will award Achievement Certificates to hams who take an active part in telling the world of Michigan's unlimited resources, opportunities, and advantages. Certificates are awarded on the following basis:

1. A MICH ham submits log information and names (addresses if possible) of 15 or more contacts made to out-of-state or DX hams with information regarding MICH.

2. An out-of-state ham, including Canada, submits log information and names (addresses if possible) of at least 5 MICH hams who relate facts to him about MICH.

3. A foreign ham, excluding any resident of Canada, submits the call letters and name/address plus log information for at least one MICH ham who told him about MICH.

Only QSOs made during MICH Week, May 15 - 22, will be considered valid. All applications for certificates must be postmarked by July 1, 1976 and mailed to Governor William Milliken, Lansing MI 48902.

OVER FORTY NOVICE CLUB

Did you know that there is now an "Over Forty Novice Club" for Novices over 40 years of age? If you know of any Novices who meet the requirements please pass the word on to them. If you qualify yourself, you are welcome in the club.

An HONORARY Membership is also available to hams of General Class and above (any age) who have contacted at least 10 Novices since January 1, 1976, and can supply a list of calls and dates of contact.

You will receive a handsome certificate (suitable for framing) and a membership card for your wallet by sending $2.00, plus 25¢ for mailing and handling, to: O.F.N.C., P.O. Box 622, Carson City NV 89701.

The reason for the club is to offer camaraderie to those Novices trying for their General in the age group of 40 and over. Further, to encourage the more experienced hams to contact Novices and help them to improve by benefiting from their extensive experience. Last but not least, to maybe give a little incentive to those of our age group who are considering joining the rewarding hobby of amateur radio.

WEEKLY PROPAGATION

A free weekly propagation forecast is offered by the Telecommunication Service Center. Anyone interested in receiving the forecasts should submit their name and address to: US Dept. of Commerce, Office of Telecommunications Center, Boulder CO 80302. Ask to have your name added to their weekly mailing list. The reports include a propagation forecast of conditions for the next seven days, a summary of conditions and solar activity for the preceding seven days, a 12 month running average prediction of sunspot numbers, and semimonthly revised ionospheric predictions.

In addition, the latest six hour forecasts may be obtained at any time by phoning 303-499-8129. The recording is updated every 6 hours, seven days a week. Also included in the recording are the latest 3 hour index of geomagnetic activity and the most recent value of the solar flux reported from Ottawa, Ontario.

RESULTS

RESULTS OF THE 1975 DELAWARE QSO PARTY

Highest scoring DEL station was K3YHR with 16,064 points. Highest scoring station outside DEL was WN1UYU with 325 points.

DELAWARE Stations . . .

County	Call	Total Score
New Castle	K3YHR	16,064

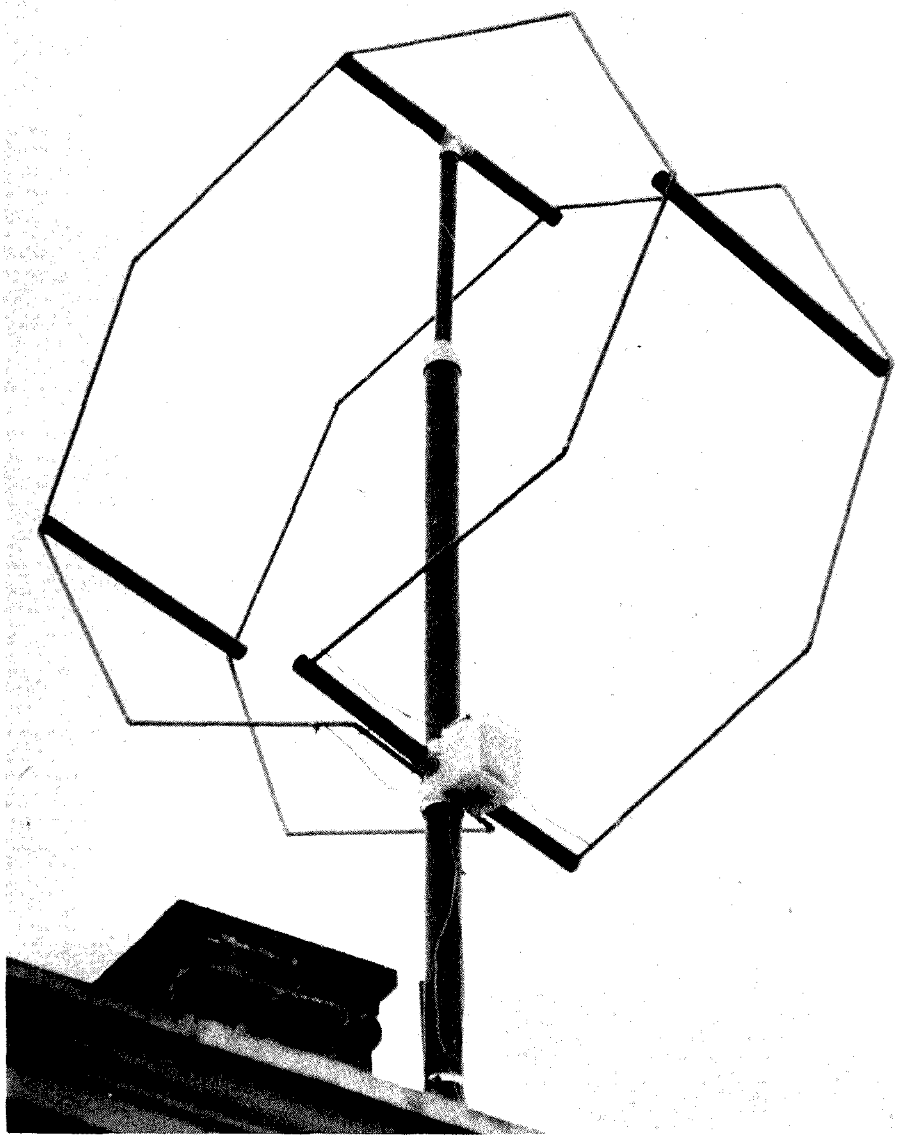
The Magnificent Sevens Microhelix

7 feet, 7 MHz

The matching of a low band antenna of reasonable performance to either the high impedance of the Novice wallet or the much less than a quarter wavelength size of a city lot is a problem which not only faced me when my ticket arrived, but also can crop up on field day or in portable operations. When you only have room for a ten meter antenna and most Novice activity is on 40 and 80 meters, obviously you need a little of that spirit you sometimes hear from an old timer when he recalls the days when a rig was improved by rebuilding, rather than giving up two months pay for another brand or later model.



Clearly, for a single band antenna, the frequency range of interest is quite narrow, covering 500 kHz at most and extending only 50 kHz (if only the Novice portion of the band is tuned). It is well known that an antenna whose size is a small fraction of a wavelength can provide an output equivalent to the full sized version, provided it is properly matched and losses are kept low. As the size of an antenna is reduced, a reactive component of the driving point impedance appears, and must be cancelled by one of opposite sign to leave the purely resistive radiation resistance term. A further complication is that as the antenna is made smaller and smaller the reactive cancellation becomes more and more frequency-dependent, requiring a "tuning" of the antenna as its operating frequency is changed.

Another undesirable side effect of the reduction in size

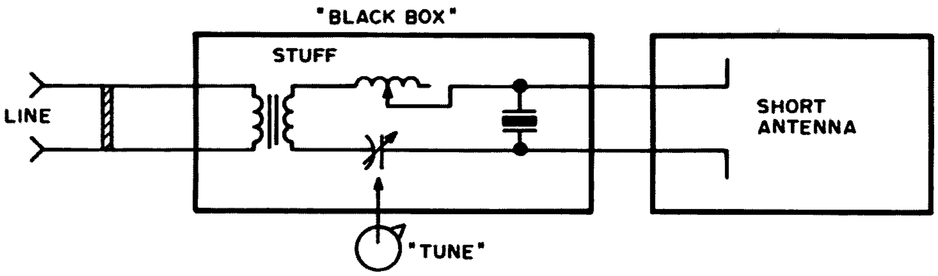


Fig. 1. The "nub."

is a reduction in the value of the radiation resistance, so that, even when the reactive components of the driving point impedance are eliminated, a transformer of some kind is required to raise the resistive portion from a value (in some cases) as low as a fraction of an Ohm to something suitable for matching a transmission line of reasonable dimensions.

Thus, the conceptual nub of our problem is a black box providing the matching functions necessary to make our small antenna have an output equivalent to a large one, i.e., to convert the undesirable output characteristics to those required to match the feed line. I found much poo-pooing of tuned small antennas among amateurs, because of the high losses found in most standard matching networks (although W2FMI has done much work with this approach and has reported excellent results in many *QST* articles). It seems to me, however, that many of these problems have arisen because attempts were made to actually build a "black box" full of coils, caps and stuff, rather than to allow the black box to remain simply a concept, which is then used as a starting point for thinking.

Let us do some thinking about losses. Losses in the antenna itself increase as the size of the antenna is reduced and it becomes more and more reactive. This is because increased reactance results in larger and larger currents flowing on the antenna, causing it to act more as a heater than an antenna. The answer is to make our antenna out of some low resistance material like silver and, further, to increase the surface area where the currents are flowing as much as possible, since heating is an I^2R effect and a small reduction in current density makes for a relatively large drop in losses. Hence, wire is out! Large diameter low resistance pipe is *in*. For experimenting, I chose easily soldered copper tubing in a relatively inexpensive and lightweight ½" size.

As an aside, I would mention that I once saw an article for the construction of a small low frequency antenna from steel exhaust pipe. This is the worst possible choice, since it is heavy, hard to work with, relatively resistive, and throws in, as a bonus, magnetic losses not found in non-magnetic metals. If your shack is heli-arc equipped, one inch or so diameter aluminum tubing would probably result in a much lighter antenna.

Our small antenna problem is now reduced to determining the configuration into which our pipes will be soldered, so that the antenna will become its own impedance matching network. Since it is usually much easier to step an impedance down (rather than up) without a transformer, we can ask, "Are there any short antennas with resistive terminal impedances larger than standard coax?" An inspection of short dipoles, loaded whips, etc., is discouraging, but wait! Again it's J. D. Kraus to the rescue. In his classic *Antennas* textbook we find that the small helix can have this property.

An examination of a typical impedance plot for a helical antenna, as given in Kraus and sketched in Fig. 2, shows that when the circumference is on the order of a wavelength, the terminal impedance is mostly resistive and loops around a value suitable for matching a standard coaxial line for a wide range of frequencies (producing the well-known broadband matching characteristics). In this size the helix radiates along its axis and hence is called an "axial mode" of propagation. As we go lower in frequency or build smaller and smaller antennas, these loops suddenly become very large and now pass quite quickly through the purely resistive points. Moreover, the antenna now radiates perpendicular to (i.e., "normal to") the axis of the helix and is thus termed the "normal mode" of propagation. For normal mode operation we are usually talking about maximum dimensions of less than one-half wave. In conclusion, it is seen that the normal mode helix has two useful operating points where the reactive impedance is zero: one where the resistive value is low (which would give rise to a matching problem equivalent to that of a short dipole), and also a high resistance operating point with a value much greater than standard coax (that can easily be matched by a tap down arrangement so that the antenna can, in effect, act as its own matching transformer).

Now that you know where on the impedance plot you wish to operate, the trick is to put that point at the frequency at which you wish to operate. Since an alteration

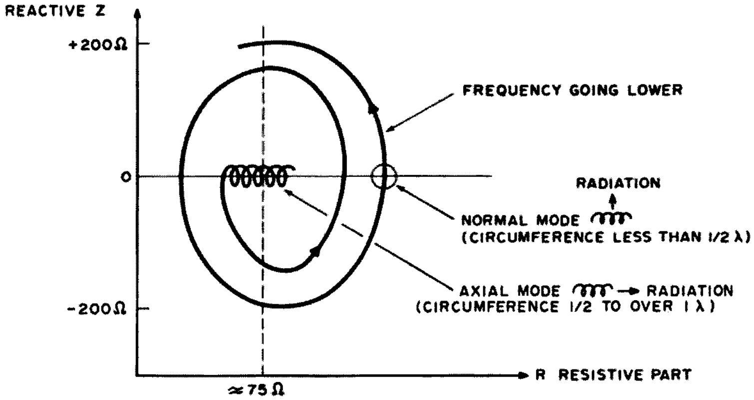

Fig. 2. Helix terminal impedance.

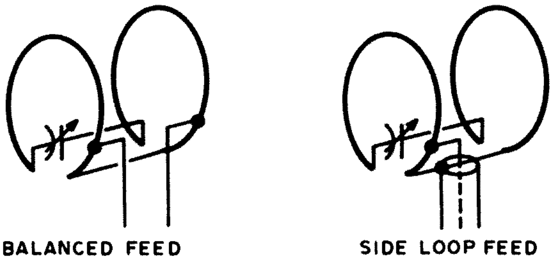

Fig. 3. Feedpoints.

of the scale of the antenna is more or less out, I chose an end-loading capacitor ($\approx$ 40 pF) between the two loop ends to electrically alter the antenna's apparent length. This has the disadvantage of putting your tuning element at the high voltage point of your antenna, but does result in a small C variation (thereby resulting in a wide tuning range, which, with careful construction, does not arc over at Novice power levels). Other tuning methods are possible, including warping the antenna to alter its size (which would probably be a superior method if high power operation were a goal).

I am not going to be too specific on the actual construction details, since this project is basically a junk box el cheapo affair. Each loop is made by the mathematical operation of dividing four ½"D 10 ft. copper tubes into four 30 inch pieces each, and using standard 45° pipe fittings to solder up 2 octagons, about 2 meters across. They are not completely joined, however. One connection is left unmade, where the two loops are joined crosswise by a short piece of tube and two 90° elbows to make a 20" separation between the joined ends of the loops. The other ends are stretched out to 39" when mounted and the tuning capacitor is connected between them. The whole works is supported on a mast and crossmembers made of ABS plastic sewer pipe. I have found that the availability of sewer pipe and fitting varies considerably from time to time and from store to store, so I leave it to you to resonate the bins at your local plumbing supply to get a combination that will work. Metal supports and towers will tend to soak up your power, so try to keep them away – but if you use much pipe as a mast, probably 6" ABS would be better than the 4" I used. I have survived 60-70 mph winds on 4" but as you can see in the photo my mast section is very short. As a finishing touch, the copper can be cleaned and sprayed with clear plastic to protect it from corrosion.

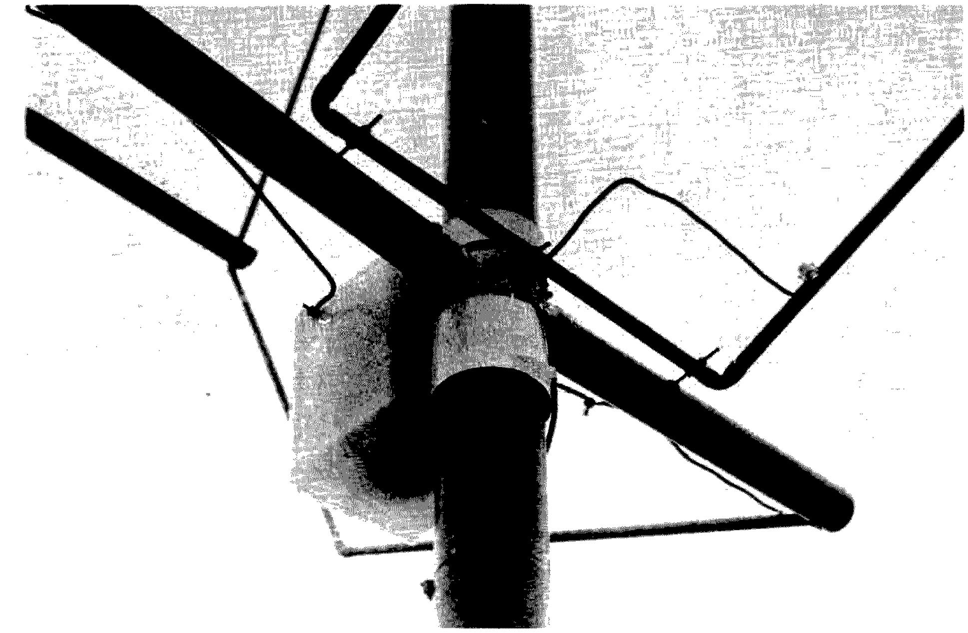
Finally, I would just like to say a few words about the tuning capacitor. I would suggest a plate spacing of at least ¼ inch. This may seem large, but remember that it is located at a high voltage point on the antenna and I had some trouble with arc-overs in damp weather. A vacuum variable would be the optimum, but tends to be rather expensive (even surplus). If you only wish to tune the Novice band, a tuning motor is not necessary, but I predict that if you don't take time to install one, later you will wish you had (especially since I've noticed a slight shift of tuning point with the weather). I used a plastic refrigerator box to protect the capacitor and motor from the weather, and silicon bathtub seal is great for waterproofing the lid. In choosing a motor you will doubtless find as I did that you really need one much slower than you would think. My ½ rpm still seems rather fast. BE SURE THAT BOTH THE STATOR AND ROTOR OF THE CAP ARE ISOLATED FROM GROUND (MOTOR). I used plastic for the mounts and a ceramic shaft insulator.

Optimum feed is a balanced connection at symmetrical points on each loop (as shown in Fig. 3) with a balun if coax is used, but my loop feed to one side also seems to work with coax and is cheaper. Good low loss connections are also important in this feed network as well.

Now that our basic plan of attack is laid out we can begin to examine the specifics of helical antennas. We note that there are several critical dimensions suitable for variations in experimenting, including the turn diameter, the pitch of each turn, and the number of turns. Helical antennas can be built with or without ground planes, but since the ground plane is just a device used to eliminate the construction of the other side or "image" of an antenna, and since it has been my experience that a ground plane really has to be large and relatively conductive to be effective, it seems to me that unless you have a copper roof it is far easier to just build the image structure than to construct a huge ground plane to save a few feet of pipe. There is a relationship between circumference and pitch which results in circular polarization and is given in Kraus as

$$C_\lambda = 2 S_\lambda,$$

where C_λ and S_λ are the respective circumference and pitch in fractions of a wave-



length (but I see no special advantage in insuring circular polarization for amateur use).

The final choice of circumference, pitch, and number of turns now becomes a matter of experimentation and the antenna "arts." As a rule of thumb, it probably pays to make the diameter as large as the mechanics of mounting it allow and, for simplicity, I chose n equal to one (i.e., one turn on each side). The pitch can go from zero to any reasonable value, and it is interesting to note that in this light the mysterious DDRR antenna would appear to be nothing more than a normal mode helix of pitch zero with a ground plane. The pitch on my final antenna version was determined experimentally and was used only because it seemed to work the best, rather than because of some long-winded theoretical justification. I used small ¼" copper tubing for my feed connections.

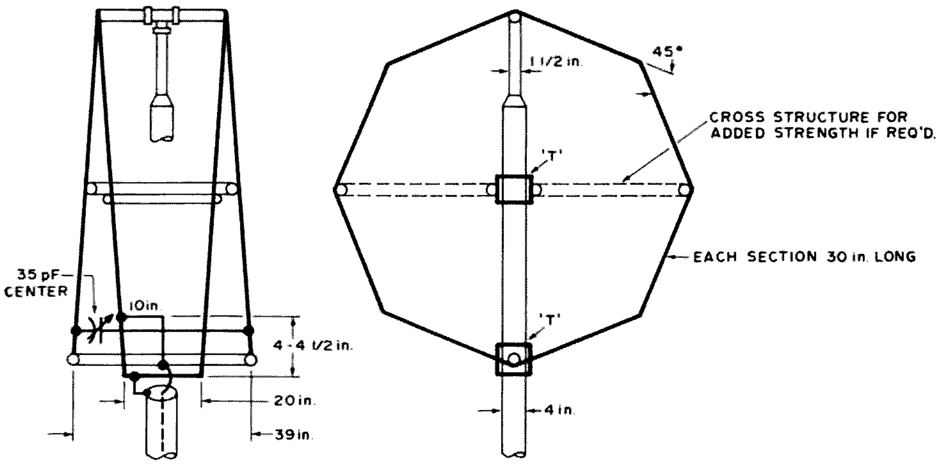


Fig. 4. Forty meter normal mode helix.

The antenna pattern is directional, having a figure 8 dipole pattern when mounted with the helix axis horizontal and a low angle omnidirectional radiation when mounted with the helix axis vertical. For all around use with both high and low angle radiation, the horizontal mounting is best, while for DX a vertical axis mounting with the antenna ¼ wave above the ground should give optimum results.

The swr of the antenna should be less than 2 over the entire Novice band and should be phenomenally close to 1 at the frequency to which the antenna is tuned — if your matching tap is properly located.

I have compared this antenna to a wire dipole and found it to be only a little over one dB down. Here in the city, however, the big problem is not signal but noise, and the helix clearly had less noise pickup than the dipole. Weak signals that were nearly obscured by noise with the dipole were easily copyable with the helix. ■

An Allband Inverted Vee

Eugene G. Preston WA5FGC
906 Cedar Glen
Austin TX 78745

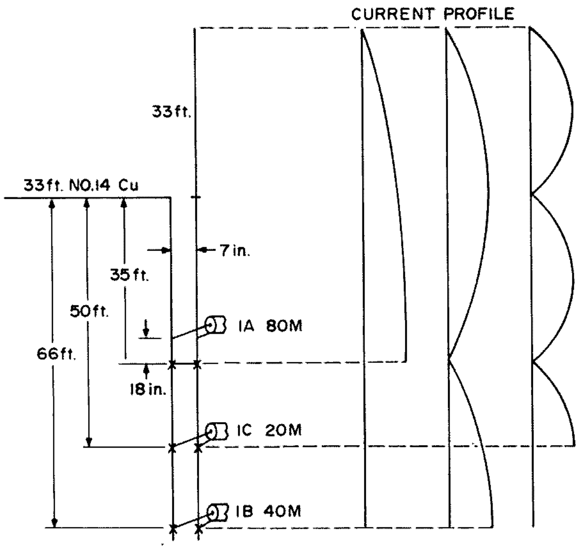

Fig. 1. First allband antenna.

An allband antenna system has usually meant an antenna farm. The original objective in this case was to have just one antenna, without loading coils or traps, that would fit in the restricted space at this QTH, yet be able to operate efficiently on all the high frequency ham bands. The task did not appear to be easy.

Several antenna systems described in the *ARRL Antenna Book* were successfully used during the last three years, but each had some problem that would finally be cause for rejection. The main problems encountered were rf burns from touching the rig while operating, arcing, coil overheating, the need to slightly retune the transmatch after QSY, and poorer signal reports when compared with an ordinary dipole. The decision was made that the antenna system should incorporate the following characteristics:

1. A single section of 50 Ohm coax from the transmitter to some remote point helps minimize rf problems in the shack, especially if the coax is buried for several feet.
2. A single section of open wire transmission line would be used as a matching element. The only adjustable connections to this line were to be a jumper or shorting element and the coax itself. Series switches, shunt matching stubs, and shunt variable capacitors were ruled out.
3. The antenna was to be a single inverted vee. The open wire line would feed the inverted vee in the center to maintain an almost balanced radiating system.

Two antenna systems were developed and tested. Figs. 1 and 2 are schematic representations of the two systems, showing dimensions of the elements and the coax tap location for operation on different ham bands. Figs. 3 and 4 show swr curves associated with Figs. 1 and 2, respectively. The center frequency of all these curves can be easily shifted by relocating the coax tap point.

There are three different ways the open wire line can be used. The first matching technique is shown in Fig. 1A. Short dipoles can be easily resonated by positioning the jumper at the maximum current point on the line. The coax feed point for 50 Ohms will be a short distance from the jumper if the current in the line is large. This method simply makes the line look like an autotransformer. A perfect match can be obtained for a specific frequency, but the antenna has an undesirably high Q.

The second matching technique is shown in Figs. 1B and 1C. This is the best and most interesting matching technique. The 650 Ohm open wire line has an almost magical ability to match an inverted vee of any length if the inverted vee is not too short at the lowest desired frequency. Equations for half wave and quarter wave matching are well known for cases where the antenna is a half wave or full wave inverted vee, respectively. What is not so well known is that the line will also match any other antenna length provided the length of one leg of the inverted vee and the length of the line sum up to an odd multiple of a quarter wavelength. This fact, which was discovered by experiment, is the basis for the success of this unique matching system. From a reactive standpoint the length of the antenna is no longer of significance since a line length can always be found to compensate for the antenna reactance.

The third matching technique is shown in Figs. 2A and 2B. The coax feed point is put further down the line than the maximum line current location. This increases the resistance to 50 Ohms but also introduces series inductive reactance. A variable capacitor is introduced in series with the coax and line to tune out the inductive reactance. In Fig. 2B a shunt capacitor makes a voltage divider if the resistance is greater than 50 Ohms. Notice the highly useful double resonance condition produced by this circuit as shown by the swr curve in Fig. 4B.

Construction of this

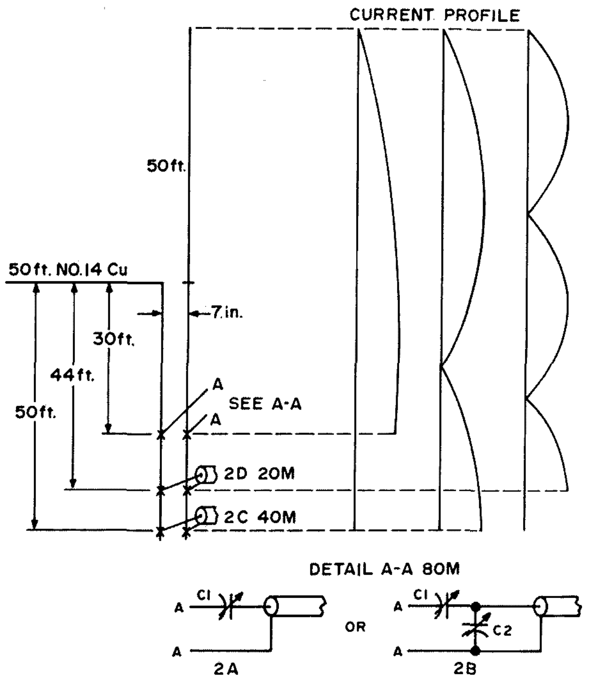

Fig. 2. Second allband antenna. Note: A jumper placed ¼λ down the line may improve the swr on 20, 15 and 10 meters.

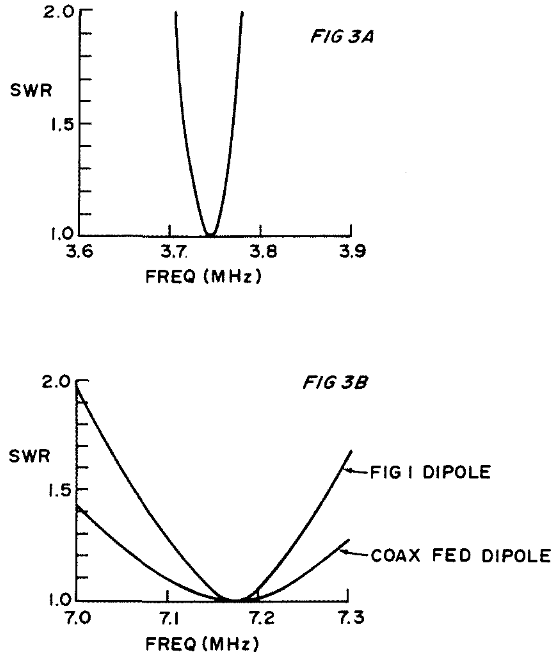

Fig. 3. Swr curves for Fig. 1.

antenna system is simple since tuning is done after all elements have been erected or installed. The inverted vee is a 100 foot roll of number 14 copper wire that was cut into two 50 foot sections. The open wire line was made from another 100 foot roll of number 14 copper wire. The tower used for center support was constructed from three 18 foot, 2 x 4 sections of wood and has a height of 30 feet when raised. The open wire line is brought down the tower using TV type standoff insulators for support and spacing. They are screwed directly into the wood to provide six to seven inches spacing between the open wire conductors. The number of supports should be minimized to reduce losses from leakage currents. Also, the TV type supports will need additional insulation if arcing is observed. A one inch length of RG/8 insulation slipped into the TV spacer with the number 14 wire run in the center of the insulation has worked well for me, even in rainy weather. Since the open wire line is longer than 30 feet, it is continued along the side of the house with the same construction techniques just described.

Several months' operation on the air providing signal strength comparisons with other hams and the ability to be heard in pileups was convincing evidence that this system performs as well as a farm of dipoles. Although the antenna shown in Fig. 2 tunes broadly on 80 meters, the shorter antenna in Fig. 1 produced comparable reports. The Fig. 1 antenna would be ideal for the Novice who wants to operate on 80, 40 and 15 meters with a single 40 meter dipole but is restricted to a narrow frequency range or has insufficient property for a full 80 meter dipole. The antennas and their matching systems described in this article have eliminated the transmatch, reduced rf in the shack, reduced antenna losses, reduced antenna costs, and increased the frequencies available from a single inverted vee antenna. ■

Squaring the Conical

If you don't mind having an antenna in your yard which looks a bit like a piece of modern art, the conical monopole has some extremely interesting advantages. The form described here can be constructed inexpensively from TV masting and lots of wire. It is extremely rugged and stormproof since, as will be seen later, it is practically the equivalent of having a 30' high TV mast guyed by about 200 small guy wires!

The conical monopole as such is not a new form of antenna. It has been widely used on VHF and sometimes on the HF bands, formed in its usual circular shape as shown in Fig. 1. It is a vertically polarized antenna and offers extremely broad bandwidth while maintaining a low swr. In a sense, it is similar to the wide-band discone antenna, although it does not have the large "tophat" element required of the discone. The antenna functions over a broad frequency range because the circumference of the cone-shaped monopole becomes resonant at different frequencies as determined by the extent of the circumference variation from top to bottom of the monopole. Within the frequency range for which the antenna is constructed, therefore, it is continuously in resonance rather than just being resonant in certain distinct bands. A typical frequency range spread for such an antenna is about 4:1 although this will vary a bit depending upon the exact design used.

The design presented in this article covers basically from 80 through 20 meters. However, it will show good performance up to about 19 MHz or so. So, if the 18 MHz band ever becomes a reality in the distant future, the antenna would, in fact, continuously cover 5 amateur bands (80, 40 and 20 plus the proposed 12 and 18 MHz bands). The antenna is fed directly with 52 Ohm coaxial cable and requires no additional tuning devices. A simple loading coil can be switched in at the base of the antenna to extend its range to 160 meters, if desired, and it should show very creditable performance on this band – especially if a reasonable ground radial system is used. If one has the real estate available, more than one antenna could be used to form a directional array by proper phasing of the current fed to each antenna. Since the spacing of the antennas would be fixed physically but vary electrically on the different bands, this would mean, however, that the phasing lines between antennas would have to be changed on each band.

The basic conical antenna as shown in Fig. 1 would seem to present some almost impossible constructional aspects on the lower frequency bands if the classic formula dimensions of the antenna were maintained. For instance, for basic 80-20 meter coverage the overall height has to be 32 feet. This dimension is not impossible, of course, but the upper and lower rings of the monopole have to be about 6 and 18 *feet* in diameter, respectively. Constructing an 18 diameter ring of lightweight tubing is

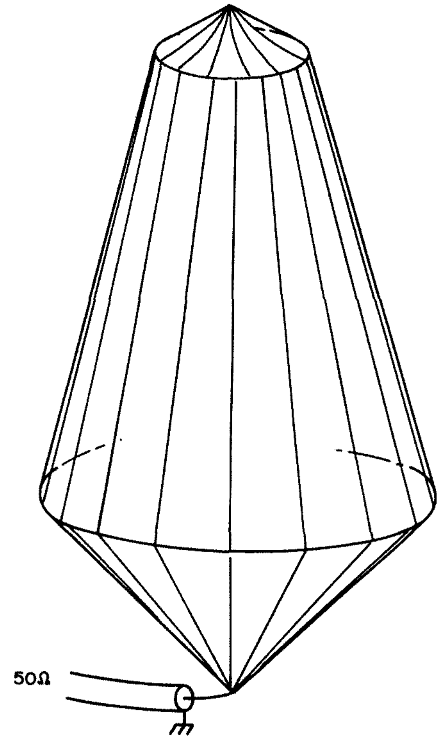

Fig. 1. Basic discone monopole antenna is frequency independent over about a 4:1 frequency range.

hardly a simple matter for the average amateur.

The circular form of the antenna is important if absolutely omnidirectional radiation characteristics are to be achieved. But, only a slight deviation from this characteristic will result if the antenna is made square in shape instead of perfectly circular. The radiation from the corners of the antenna will suffer a bit (perhaps 3-5 dB down), but it should not be difficult for any amateur to orient the antenna with the aid of a great circle map centered on his QTH such that these points fall into areas which are of minor preference. The other advantages of this form of antenna should far outweigh this disadvantage.

A "squared-off" conical monopole for 80-20 meters is shown in skeleton form in Fig. 2. Not every wire is shown for the sake of clarity. The total mast height above the base insulating section is 30 feet and may consist simply of telescoping TV mast sections. The height from ground to the insulating section may be 2-3 feet. The upper square is located about 2 feet from the top of the mast. Each side of this square is 6 feet long. The square can be constructed from metallic tubing, but a better choice is probably PVC plumbing type tubing using the right angle fittings easily available for this type of tubing to form the square. Holes are drilled through the tubing for each wire element and a fixing wire placed around the entry and exit points of each wire to keep the overall square in place. At the top of the mast, each wire element is secured to a ring which metallically connects it to the mast.

At the base of the antenna, four approximately 6 foot tall guy posts are installed spaced 16 feet apart and centered around the central mast. The lower ring of Fig. 1 is simulated by an *insulated* wire ring running

The conical monopole is a vertically polarized antenna that offers extremely broad bandwidth while maintaining a low swr . . .

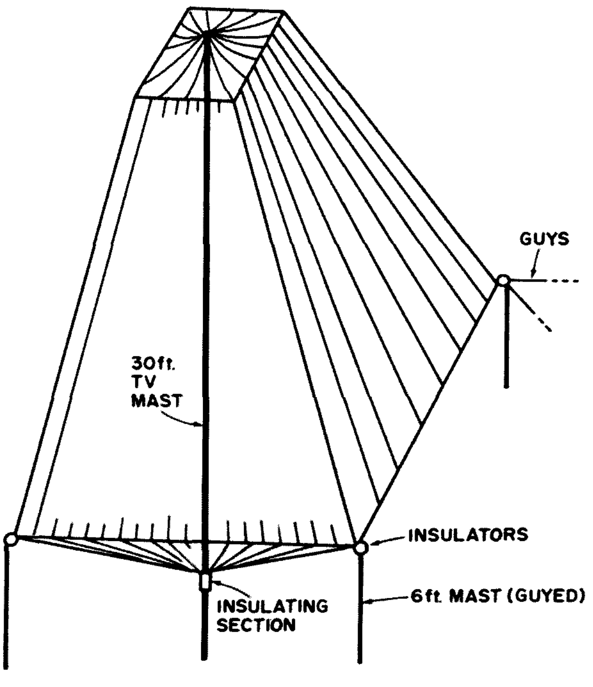

Fig. 2. Squared form of antenna form shown in Fig. 1. Distance between 6 foot masts is 16 feet. Other dimensions are discussed in text.

around between the four guy posts. This wire should be particularly taut, and it may be advisable to guy each guy post in two directions, depending upon the type of soil encountered. Each wire element from the top of the antenna is run through the upper square, then to the lower wire ring (where it is soldered or clamped to the wire ring), and then to a collector ring just above the insulating section on the central mast. The spacing between the wires as they reach the lower wire ring should be about 3 inches. Belden copper-bronze antenna wire is particularly suitable, but any good antenna wire of the copper-bronze or copperweld variety will more than adequately suffice.

The center conductor of the coaxial feed line should be connected to the wire collector ring above the insulating section on the central mast. The shield is connected to the mast support pipe going into the ground. Although this type of antenna is less dependent upon ground radials than the usual type of single element vertical antenna, ground radials will improve its performance. But, again because of its unique design, the antenna does not require ground radials of the usual length as single element quarter-wave vertical antennas. A group of 10-12 radials, each being 16-17 feet long, will suffice for normal operation, although numerous experiments have shown that a greater number of radials will improve the low angle radiation characteristics for DX purposes. Experiments have also shown that ground radial extension in the direction of desired DX performance will considerably improve performance in that direction. For instance, say one does have room to bury 16-17 foot radials all around the antenna but one's particular DX interest is South America. By making the radials pointing in the South American direction as long as possible (34 feet to infinity), considerable improvement in low angle DX radiation in that direction will occur. A rough estimate is that radials one wavelength long in the desired direction result in a 3 dB gain at the low vertical angles useful for DX purposes.

The squared conical monopole is certainly not the overall answer to HF antenna problems, but it does offer reasonably omnidirectional coverage and coverage of the main HF bands usable during the present sunspot cycle. Since the swr to the antenna also remains less than 2:1 over its design range, it also serves as an excellent antenna companion to the various solid state transceivers on the market which have broadband transmitter output circuits (non-tunable). These circuits demand for maximum power output that the antenna transmission line they work into presents a very uniform low swr pattern on each of the bands involved if the "instant" bandswitch advantage of these rigs is to be a realistic operating convenience. ■

Secret Antennas for Cliff Dwellers

J. Craig Caston WA6PXY
5403 Newcastle Avenue #20
Encino CA 91316

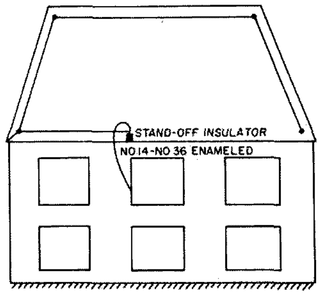

Fig. 1. One way to avoid publicity is shown here. If possible, wire small enough not to be seen, but strung low, will do a good job.

There have been countless articles published about the various antennas that can be adapted for those of us who live in the wonderful world of "urbanville." Whether it has been for convenience or necessity, many amateurs today find themselves living in an apartment, a small city lot, or the popular condominium. Admittedly, this kind of living has its advantages. But one of the greatest disadvantages for radio amateurs, however, is how and where are you going to erect an effective antenna?

After moving from a house into an apartment, I found myself confronted with this problem. I learned, sometimes the hard way, what can and cannot be done. This article will present various configurations involving what I believe is a functional all-band antenna system that anybody can use successfully, which is something that most other articles discussing antennas for urban dwellers seem to ignore.

To start, let's be honest about one always overlooked fact: the utilization of an indoor antenna. Forget it. Unless your dwelling is built of wood, it is a totally futile effort. Modern buildings are made of concrete and steel, all components that love to block rf. You may occasionally hear and work somebody with an indoor antenna, but that kind of situation is truly like working into a dummy load!

Even hanging something outside a convenient window opening will not really suffice, especially if you're looking out to an apartment canyon like I do. Remember, antennas, to work effectively, have to be installed clear and free of nearby objects.

Second, if you are planning to move into a building that requires permission for an outside antenna, and that includes most of us, just ask the manager about the possibility of erecting one. It took me three months to obtain permission to erect a simple vertical, but my persistence paid off. If the building's manager has misgivings over such an arrangement, explain to the person carefully what you plan to do. In fact, a little persuasion on your part might turn into a blessing in disguise.

But even if you are not plagued with space or permission problems, and need just an effective antenna for 80 or 160 meters, then I have the antenna for you. What I am talking about is the end-fed, random length antenna — an antenna that is easy to construct, and yet so effective.

In terms of cost and simplicity, the end-fed is hard to beat. However, the only time anybody sees the end-fed configuration nowadays is usually around the Field Day site.

The limitations of my home brew vertical led me to try the end-fed, random length idea. A single strand of #24 enameled wire was hung out my window, led up the roof, and strung over a pole to the other end of the building, all 200 feet of it. When completed, I had an all-band, end-fed, inverted-vee type random length antenna, minus the transmatch, for $1.29! A real winner in these peculiar times of inflation and recession.

Description

A true end-fed random length antenna can be several wavelengths long.[1] It is not necessary that it be cut to resonate for any frequency; therefore, any convenient length will suffice.

As a rule of thumb, you

should not make the length of the wire shorter than one-half wavelength at the lowest frequency planned to be used. This means that for 80 meters the antenna should be approximately 125 feet long. For 40, 66 feet. However, one source states that an end-fed can be utilized effectively down to one-quarter its lowest frequency and still work well.[2]

This may sound like a contradiction to the random length idea, but in relation to all other frequencies the wire will look, you might say, randomly long.

Installations

Before erecting the end-fed antenna you should first plan the site in which it is to be strung. Doing so will facilitate the actual erection of the antenna, especially if it is to be done in a secretive way. By viewing the roof and designing a mental picture of how you want to place the wire, you can easily rearrange the antenna in your mind, thus avoiding any erection problems later on.

The best method is to have the wire attached to a pole on the roof, the higher the pole the better. But, if for any reason the antenna cannot be strung on the roof, attachment to an adjacent building or down to an open field will do just as well. That's the beauty of the antenna – its versatility.

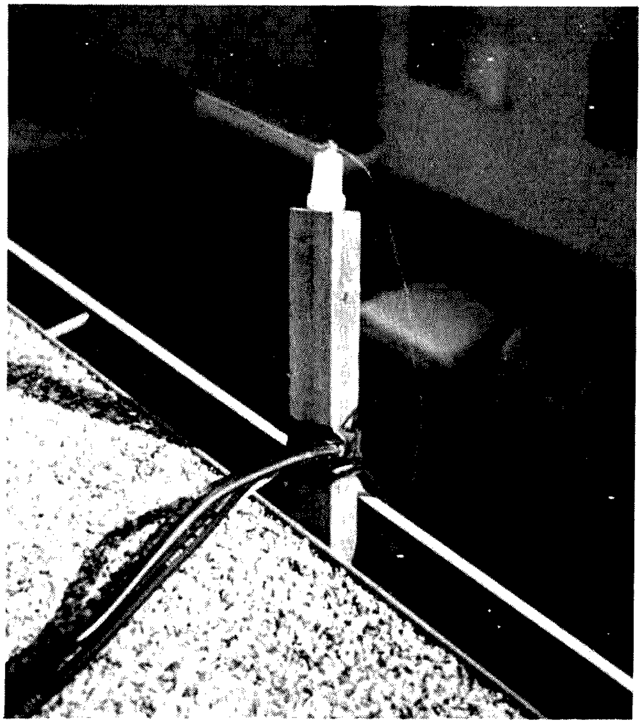
I've already mentioned that getting at least part of the antenna in the clear is probably the most important consideration. This fact cannot be overemphasized, because the efficiency of the whole system depends upon the antenna's being in the open somewhere along its length. Figs. 1 and 2 give a couple of ideas on how this could be accomplished.

It is suggested that solid enameled wire be used for the antenna element. Enameled wire is cheap, convenient, and it is easy to handle – you just wind it off the roll. Moreover, enameled wire can be strung, if necessary, without the use of insulators because of its protective coating. To avoid unwanted publicity, #34 or #36 wire is a good choice. Your decision on the right size will depend, again, on your own situation.

Widely different wire sizes will have a negligible effect on performance. It has been proven that wire as small as #36 can work well and handle high power levels just as easily as #12 or #14. How far you can go in power on a thin wire antenna, without damaging it, however, will have to be determined experimentally.

Where needed, insulators can be made of anything that insulates. For deceptive purposes clear plastic or plexiglas cut to suit your needs will do. Also small diameter vinyl, fishing line, or plastic tubing is a good choice to consider since it can be tied to support structures easily.

An effective way to lead the antenna up to the roof, if you use that configuration, is with stand-off insulators (see photo). Again, the proper choice and placement of insulators will depend upon your needs.



An insulator on top of a piece of wood stuck into the rain gutter is one convenient way to lead the antenna up to the roof.

One of the nice things about the end-fed antenna is that it requires no lead in. One end of the antenna, as the name properly says, is fed the power. However, because different impedances will be presented at the feedpoint of the antenna, depending on which band you operate, a tuner will be required.

Tuner Considerations

As you probably know, a simple coil and capacitor arrangement is all that's needed (Fig. 4). If you want to spend the money, a commercial unit will do nicely. But constructing a tuner yourself can be achieved without too much difficulty or expense. On power levels up to around 200 Watts, a broadcast band variable out of an old receiver and an

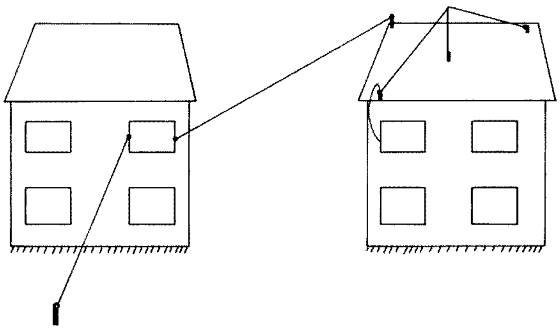


Fig. 2. Here are three ways an end-fed can be used around a building. Note that in all three examples, the wire is reasonably clear of objects somewhere along its length.

inductor of about 30 uH will do the job.

A check into a parts catalog will list a number of coils and capacitors that can fit your own needs. My tuner uses an E. F. Johnson roller inductor #229-203. This coil works beautifully. If you can pick one up, it is suggested you do so. Unfortunately, it has been reported that this inductor is no longer in production. A little searching, however, might produce one at a moderate cost.

C1 is a Johnson type E transmitting capacitor #154-10. It's rated about 350 pF at 3 kV. These components were chosen with the thought of using higher power in the future.

Installation of L1 and C1 into an enclosed chassis is necessary for proper shielding. The photo should give a good idea of component layout and assembly.

As an added bonus, I found that my tuner knocked out all remaining TVI, something that apartment hams are keenly aware of since interferences into just one building's TV system could easily disturb the viewing enjoyment of many people.

Inside the Shack

Because of the tuner, a good ground system is needed. An effective ground will help prevent useless rf currents from flowing around the shack. If a decent ground is not used, the operator will face problems in achieving a minimum swr from his unit. In addition, his equipment will develop a condition of "biting" when he touches it.

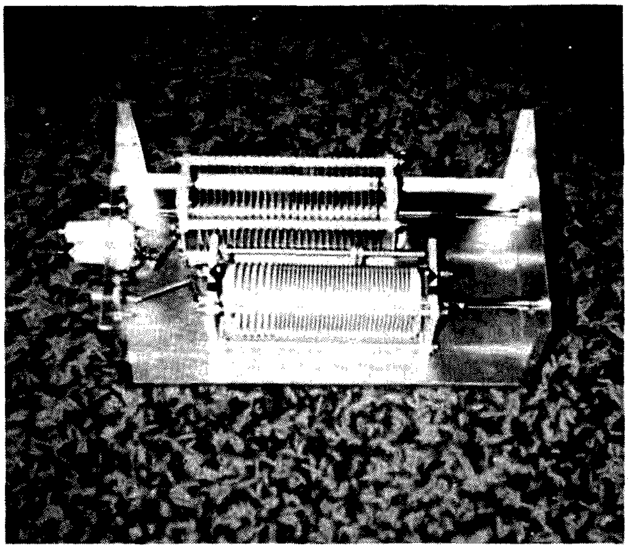
Finding a satisfactory ground is a difficult problem for apartment dwellers. This is because the most obvious ground systems may not be readily available, especially if your apartment is several stories above terra firma.

One way to "ground" the tuner is to use a counterpoise or artificial ground. This is a wire one-quarter wave long of whatever band you use placed conveniently around the shack. The only drawback to this idea, however, is that to be effective at least one wire must be installed for each band. I have one counterpoise in use now. It's cut for 40 meters even though I frequent 80 as well. Therefore, it's possible that you might be able to get by using just one counterpoise for two bands.

Another way to help eliminate stray rf currents is to try to terminate the antenna wire at a current loop. This involves using a length or antenna cut for your favorite band at least one-quarter wave long or multiples thereof.[3] This minimizes the amount of rf introduced into the shack. Doing this is not imperative, but it might aid in stopping a hot rig.

If you can connect the tuner with a short piece of wire to some grounded water pipes or something of similar nature, then you're in good shape. In addition to the counterpoise, I have a wire running from the shack and connected to the pipes in my bathroom shower. Quite surprisingly, this eliminated most of my ground problems.

Those wishing additional information can find an excellent article on tuners in the December, 1974 *QST* by DJ2LR/W2[4], or consult *The Radio Amateur's Handbook*.



A look at the home brew transmatch. Note the standoff insulators, and the placement of L1 and C1 in the spacious chassis.

Conclusion

The performance of the end-fed system at my QTH has been very gratifying. DX on 40 and 80 meters has been easier to hear, while signal reports with only 200 Watts of power have been excellent from stateside stations.

It's hoped this primer will guide the amateur in making the right decisions involving the end-fed concept which fit his own individual and unique situation, while at the same time giving the amateur plagued with space and permission problems a chance to enjoy his or her hobby with a minimum of difficulty. ■

The Novice Inverted Vee

Jerrold A. Swank W8HXR
657 Willabar Drive
Washington Courthouse OH 43160

One of the most popular antennas is the so-called "inverted V," which is actually a dipole with the legs drooping at approximately a 45° angle on each side of a single support. The single support is the secret of its appeal, because almost everyone can find something to support this type of antenna, as in Fig. 1, where it is supported on a TV mast pulled up with a pulley. This way it can easily be lowered for tuning. However, even if not on a pulley, it's quite an easy antenna to tune, because the legs are so close to the ground.

The ideal inverted V antenna would have the included angle (a) 90°, and the legs in the same plane as the tower. It would be a little better if the top was supported about 3' away from the metal tower, to keep the tower out of the field of the antenna. See Fig. 3.

However, the antenna will work well — even in the most unusual configurations. See Fig. 2. For example, my available yard for antennas is 74' x 70', which is no way close to the ideal required space for an 80 meter V. I have two towers, 48 feet apart. Figs. 4 and 5 show the slope and separation of my antennas.

These antennas have an important amount of vertical polarization, as when angle "a" is less than 90°, the vertical polarization predominates, and when it is greater than 90° the horizontal polarization predominates. Thus the antennas are good DX antennas — better than a horizontal dipole. They do, however, show many characteristics of the horizontal dipole, being less subject to man-made noise and more to high angle radiation than the vertical. For example, when I am transmitting to K1GZL in Berlin, N.H., he says my signal is about 20 dB better from the inverted V than the vertical, but my vertical is about 3 S-units better in the Antarctic than the inverted V. When I am talking to W5VSR in New Orleans the situation varies. Some nights I am better on the V, and some nights on the vertical, and some nights I will fade out on one and come in strong on the other.

Although I am using baluns on both, there might be some advantage to not using baluns, since I am in the northern part of the country. An inverted V without a balun tends to be directional toward the side of the antenna with the shield of the coax connected. Thus the pattern without a balun tends to be skewed to one side. Whether this is an advantage or disadvantage depends on where you are and what you want. I am of the opinion that the balun is unnecessary for general use, provided that your antenna is resonant at about the frequency you work, and that the coax lead-in is a multiple of a half wave at that frequency.

Since I am using baluns, I am also using separate feed lines to the 40 and 80 meter antennas. Without baluns you can easily feed both from the same feed line, and just parallel them, thus saving quite a bit in these days of high costs (by not using two baluns and perhaps a hundred feet less of coax).

When you tune up an inverted V you will find that

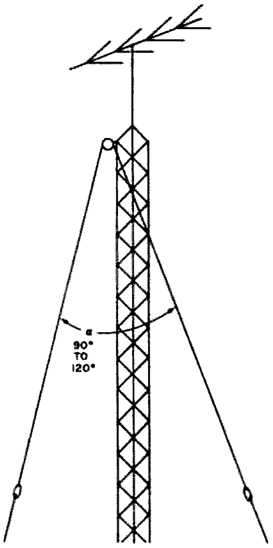

Fig. 1.

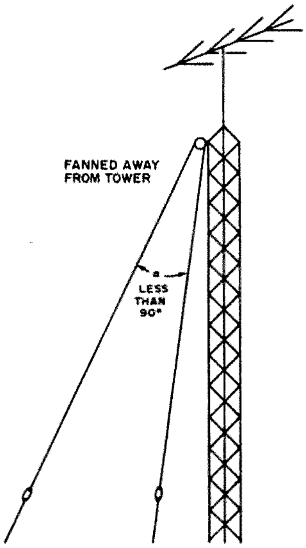

Fig. 2.

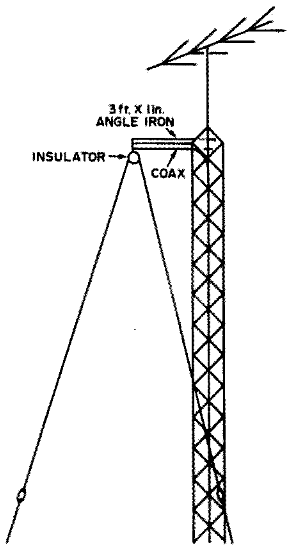

Fig. 3.

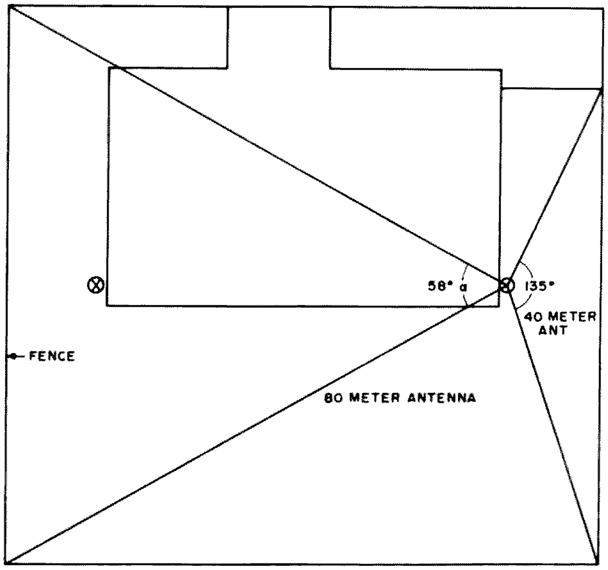

PLAN VIEW

Fig. 4.

it is very easy to tune and very easy to understand. It is best to cut it a little long, perhaps as much as two feet. When you measure it with an swr bridge it may look like it will never tune, but start taking off about six inches at a time and measure the bottom of the range you want. When it starts to go down toward 1:1 measure about 100 kHz on each side of the desired frequency, and find where the center of the range is. Don't worry if it will not go lower than 2:1 – just find the center. When you have it centered, then start to close or open the angle at the bottom, and raise and lower the legs a little. This will improve the swr, and if you have enough room you can get it right down to 1:1. At this point you will find it quite broad tuning, and probably it will cover the whole range you want with swr less than 1:1.5.

Of course, if you have to, you can pull up an inverted V into a tree, or on the side of your house, or on a piece of masting attached with TV hardware to a soil pipe or chimney.

I think that every ham should have both a vertical and an inverted V or dipole. The signals often swing greatly from one to the other. I had a ham in the Antarctic tell me one night that he had two receivers tuned to me, one on a vertically polarized antenna and the other on a horizontally polarized antenna. He put one on each side of the room so that he was seated between them and he said it was beautiful. The signal would fade from one to the other and he never missed a word.

I have given you the figures for the Novice bands, although my antennas are tuned several inches shorter for where I work.

The regular dipole at the center has an impedance of about 72 Ohms, so it is better suited to RG11 or RG59. However, the downward slope of the legs on an inverted V makes it an excellent match for RG8 or RG58.

Incidentally, at Novice powers don't waste your money on RG8. RG58 is quite adequate. The power rating of RG58 at 30 MHz is 430 Watts, and the loss of 100 feet of RG58 at 7 MHz is just one dB greater than RG8. That means you would barely be able to tell the difference. At 3.7 MHz it would be even less.

Incidentally, remember that you can use the 40 meter inverted V on 15 meters, and the 80 meter inverted V on 10 meters, so you can have an all band Novice antenna with a single feed line.

Also, if you have to put up a push-up mast or pole you can use the two inverted V antennas as guy lines. ■

Closed Loop Antenna Tuning

Tuning Yagi-Uda beams and quads can be a very time-consuming task, requiring many man-hours to perform. Usually several helpers are needed to make adjustments and to take field strength measurements. I have developed a technique which requires only one person to successfully tune an antenna with the aid of a couple of pieces of equipment. The method developed uses an rf source in the far-field and the station receiver as a sensitive field strength measuring device. A circuit is connected from the receiver to a speaker, which, in turn, can modulate a small 100 mW transmitter. The receiver for the 100 mW transmitter is carried by the person making adjustments on the antenna. Thus, a closed loop feedback system is used to permit optimum adjustment of the antenna. As a bonus, the far-field signal source can be used to make pattern measurements as the antenna is rotated, the receiver monitoring relative field strength. Fig. 1 shows a block diagram of the system.

Circuit Details

The far-field signal source is a small, low power oscillator (Fig. 2). Transistor Q_1 is used in a Pierce fundamental mode oscillator. A diode full wave rectifier is used as a frequency doubler. A small Amidon iron powder toroid is used to develop the push/pull signal needed for full wave rectification. Transistor Q_2 acts as an amplifier for the doubled frequency. Another transformer, T_2, steps the output impedance down to a low value. The crystal is chosen such that the harmonics will fall within the amateur bands. I used a 7060 kHz crystal which permits field strength measurements at 14,120, 21,180, and 28,240 kHz. The output signal is rich in the 2nd, 3rd and 4th harmonics and produces a strong source for the 20, 15 and 10 meter bands. The oscillator is powered by 2 six volt batteries connected in series to produce 12 volts. Since the current drain is low the batteries will last a long time. Two wires about 5 feet long are connected as an antenna to the output of the amplifier. Ideally, the far-field source should be at the same height as the station antenna, but useful results will be obtained by mounting the transmitter/antenna on the top of a tall ladder leaning next to a roof. The transmitter should be at least 5 wavelengths away for meaningful results.

The unit that connects to the receiver is a voltage-to-frequency converter. The voltage developed across the meter is used to vary the frequency of an audio oscillator. The maximum voltage developed across the meter can either be measured with a sensitive voltmeter or be computed. For the Heath SB-102, the internal resistance is 100 Ohms, and the full scale reading is 1 mA. Thus, the full scale voltage across the meter is:

$$V_{MAX} = I_{F.S.} \times R_M = 1.00 \text{ mA} \times 100 \text{ Ohms} = 100 \text{ mV}$$

The 100 mV signal is amplified by a 741 operational amplifier as shown in Fig. 3. The gain of the amplifier is 40 dB. Thus the S-meter full scale voltage of 100 mV would become 10 volts at the output of the amplifier. This voltage is used to drive the modulation input on the 555 free-tuning oscillator. The 555 oscillator oscillates at a frequency determined by the resistor/capacitor combination connected across it. The frequency of oscillation is given by the equation:

$$F = \frac{1.44}{(R_A + 2R_B)C}$$

For the values given, the free running frequency is roughly 1 kHz. As the 741 amplifier drives a current into the 555, however, this frequency is a little lower than 1 kHz and becomes greater as the drive current is reduced. Thus, the effect is to hear a higher frequency for a lower S-meter reading, and a lower frequency as the S-meter reading becomes stronger. The 555 drives an 8 Ohm speaker. The 470 Ohm series resistor is used to limit the current to a

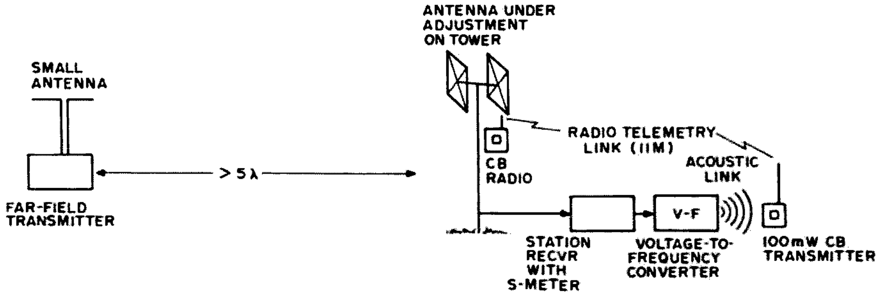

Fig. 1. Closed loop antenna adjustment block diagram. If CB radios are not available, a two wire speaker cable could be run up the tower for monitoring. Far-field transmitter is a milliwatt transmitter with harmonics falling inside the 20, 15 and 10 meter bands.

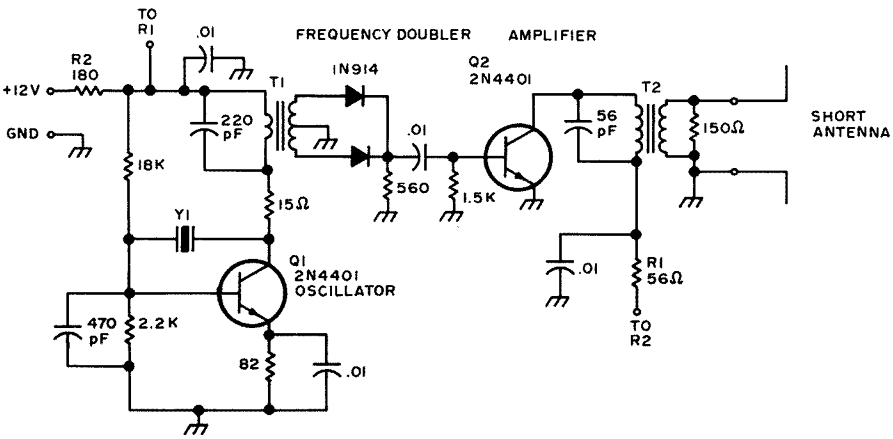

Fig. 2. Schematic of the milliwatt transmitter for the far-field source. Y_1: 7.00-7.115 MHz; harmonics fall within 20m, 15m and 10m bands; T_1: Amidon Core T50-2, primary 22 turns #28, secondary 20 turns #28, center-tapped; T_2: Amidon Core T50-2, primary 22 turns #28, secondary 5 turns #28.

safe value, and yet still permit a loud tone to be heard.

The tone from the speaker is monitored as an indication of relative field strength level. In the prototype, a 100 mW citizen's band walkie-talkie was used as a telemetry link between the receiver and the antenna on top of a tower. The walkie-talkie was taped "on," and the speaker was acoustically coupled to the unit. The walkie-talkie is a very good and inexpensive wireless telemetry link. Both units were bought for less than $10 several years ago, and similar units are still available. Since the distance between the walkie-talkies is not far, the antennas on the units can be retracted somewhat to limit their range. If it is not possible to find any walkie-talkies, then a two wire system can be rigged to permit hearing the speaker at the antenna tuning site. The wireless approach is better because there are no wires to get tangled in, and the volume of the sound can be adjusted on site.

When coupling the voltage-to-frequency converter to the receiver, a battery or isolated supply should be used to power it. This is because the S-meter circuit may be at a high potential above ground, and the return ground on the voltage-to-frequency will also be at this high potential. This high potential is called a common mode voltage. The 741 amplifier will not function if its common mode voltage is too great. If a common ground between the converter and the receiver is not used, the 741 operational amplifier will only detect the differential voltage across the S-meter and it will not respond to the common mode voltage.

Operation

The voltage-to-frequency converter should be connected across the S-meter. As a signal is tuned in, the tone from the 555 oscillator will change pitch. The far-field source should then be placed several wavelengths away and tuned in with the receiver connected to the antenna. If the front-to-back ratio is to be optimized, then the adjustment of the antenna should be done to minimize the S-meter reading while the antenna is pointed away from the far-field source. On a quad, for instance, the reflector stub should be varied until the receiver reaches a minimum signal strength. The tone from the 555 oscillator should be monitored for the highest possible pitch. The human ear can detect fairly small changes in pitch if a continuous tone is heard at all times. For front gain optimization, the beam would be pointed towards the source and the pitch from the telemetry link would be lowered as much as possible, indicating maximum frontal gain.

Once the adjustments are made, the far-field source makes an ideal reference to make relative field strength measurements with. If a calibrated output signal generator can be found, then a matched S-meter reading can be taken between the antenna and the generator output. By plotting the relative output level from the generator vs. bearing, a polar plot of field strength can be taken. The S-meter is used solely as a matching device, matching the antenna output to the calibrated generator output. It is surprising how uncalibrated S-meters are in terms of real S units to absolute units (an S unit is defined as a 6 dB change in signal strength). For signals which barely deflect the S-meter, sides of beams for instance, an audio meter may be used to match the generator's output to the antenna's output.

For antennas such as quads it is gratifying to know that optimum adjustments can be made without a number of people needed. Since the quad is fairly easy to reach from a tower, it is very convenient to be able to make final adjustments while the antenna is in place. I hope this method will create interest in different approaches to solving an old problem — how to tune an antenna. ■

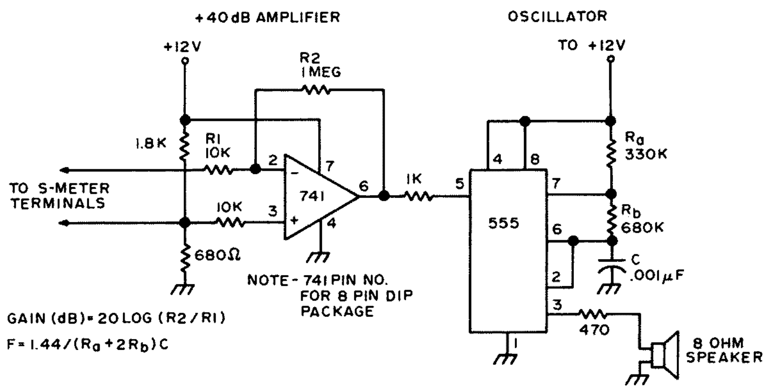

Fig. 3. Schematic of the voltage-to-frequency converter. A 100 mV input signal will cause a maximum frequency change at the output of the 555 astable oscillator.

The 75-80m Broadbander

Some time ago, I operated with an all band multi-element dipole antenna. The antenna worked quite well (for a dipole antenna) but generally left me in the bottom of pileups on 20 and 15 meters. This eventually led me to a more competitive antenna for the higher frequencies. The multi-band dipole became redundant (and worse yet, tended to distort the quad's pattern).

However, I wanted to increase the bandwidth of the 80 meter dipole, as my operation generally is evenly divided between CW and SSB operation. After some thought, the elements of the dipole for 15 and 10 were removed, and an attempt was made to extend the 20 meter element to a length suitable for 75 meter operation. Reason told me that if you could combine dipoles for 20 and 40, etc., why not 80 and 75?

Due to space limitations in the K2VGD estate, the 80 meter antenna was folded into a "Z" shape, to fit a plot 75' wide. The apex of the antenna system was at 30 feet and the ends were attached to 4 television-type aluminum masts, fastened to the fence. In attaching the 75 meter antenna, I ran the elements backwards across the two masts, thus overlapping the last 20 feet of each element. As one element was insulated, no problems with shorting were anticipated. The antenna is fed with a random length of RG-8/U and a W2AU balun.

In testing the design, the lowest swr was expected at 3550 and 3900 (the design length of the antennas). Much to my surprise the antenna exhibited high swr below 3650, but less than 1.5 to 1 between 3650 and 4000 kHz, with no peaks or dips within this portion of the band. After several days of experimentation, the length of the CW section approached the length necessary for operation at 3400, with the 75 meter antenna cut for 3900. The swr plot is included in Fig. 1.

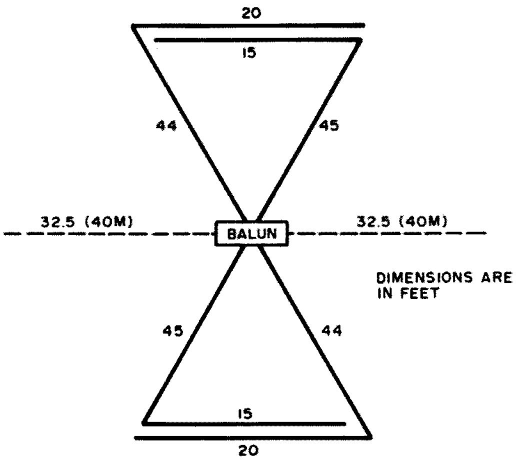

Fig. 1. Vertical view with swr plot.

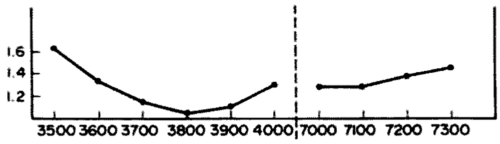

While I make no pretense of having the exact technical explanation of the results, it would appear that the ends of the antenna, in overlapping, inductively and capacitively couple the two elements to one another in such a way as to cancel the reactance that would be present at the feedpoint. Element lengths do not appear to follow theory exactly, which in all probability is due to the fact that the ends are ten feet off the ground, and the apex is but 30 feet high, far from the ideal ¼ wave height. However, there has been no evidence of very high take-off angles, as no difficulty is encountered working either with the West Coast, Europe or even as far away as New Zealand on 75 (5x8 in ZL-land with 900 W PEP).

The 40 meter dipole does not appear to be affected by the 80 meter elements. If anything, it seems to have broader than normal characteristics.

No attempt is made to convince others that "this is THE antenna" for 80 meters, but rather, with the declining propagation on the higher bands, to encourage experimentation by others in limited space, broadband systems. Most of these types of antennas use wire elements, and thus are relatively inexpensive. ■

The Magic of a Matchmaker

It isn't necessary to settle for an inefficient antenna because you don't have the space to put up a beam or a good high dipole. Even if you don't have the time to put up an antenna farm before it's time to move, or if the landlord frowns on antennas in the yard, you can still put out a good signal. The key is the use of an antenna tuner. A tuner will allow you to use almost any length of wire, and if you plan ahead a bit, you might even get some gain.

I've used an antenna tuner before, with an end-fed one wavelength Zepp on 80, so when I needed an all band antenna that I could put up in the trees, the solution was obvious. Unfortunately, someone had relieved me of the Johnson Matchbox that had served me so well. It was necessary to build a tuner.

The unit that I eventually built was the product of a little thought and a lot of scrounging. I didn't have any of the major parts needed, so I had to rely on my friends' junk boxes. Vern WB4BER came up with a high voltage capacitor, and Lloyd WA4HYT furnished a toroidal tank coil. Armed with these parts, I decided that this was one project that would look decent enough to put next to the rig, so I bought a wooden cabinet from Radio Shack ($2.00 on the "junk" table).

The special characteristics of toroids are well known. The one that interested me at this point was size. I had just bought a used FPM-300, and, if I could make a small enough tuner, maybe I could put together a suitcase-sized station. The cabinet for the tuner was in fact just the right size to fit in the suitcase.

The circuit I would use had already been determined by the parts on hand: an "L" match and variations. With this in mind, I built a haywired matcher to test the idea. I didn't know if the toroid was suitable for high frequency use and had to find out before I got the whole project finished. Feeding a 14 meter wire, results were satisfactory, and I was able to match 300, 600 and 2000 Ohm loads on the five HF amateur bands.

I replaced the original front panel on the cabinet with a piece of sheet aluminum and mounted the coil on it. The coil is actually 18 turns of #12 wire wound on two T-250 cores, with two lucite end spacers, and is probably much larger than is needed for 150 Watts of rf. I mounted the coil to a 12 position tap switch so that the switch and coil would make a compact assembly, and put the switch right of center on the panel. The capacitor, which is a 240 pF Hammarlund unit, was mounted on a piece of fiberglass on the side of the cabinet, so that both the rotor and stator were isolated from ground. Input and output connections were placed on the back panel.

Again, operating results were good. However, when I tried to feed the antenna through coax, I was unable to get a match on any band. The cure for this was to increase the matching circuit variations available. This was done by wiring in a 3 pole 5 throw ceramic switch. This was originally a 4 pole unit, but between 10:30 and 11:00 pm I broke one of the wafers, and it took a little thought to come up with the circuit changes necessary. Incidentally, besides being ceramic, the switches have silicone

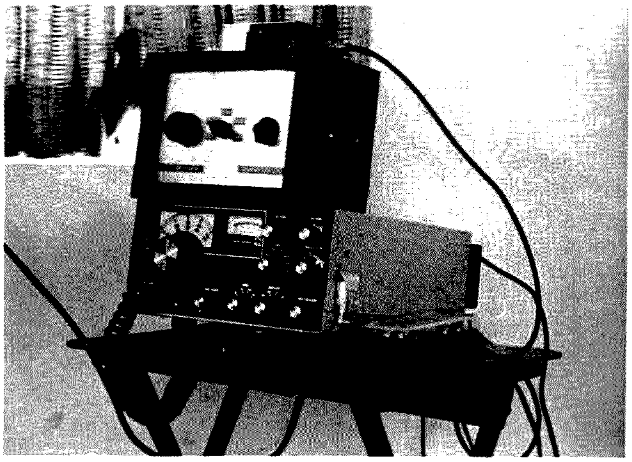
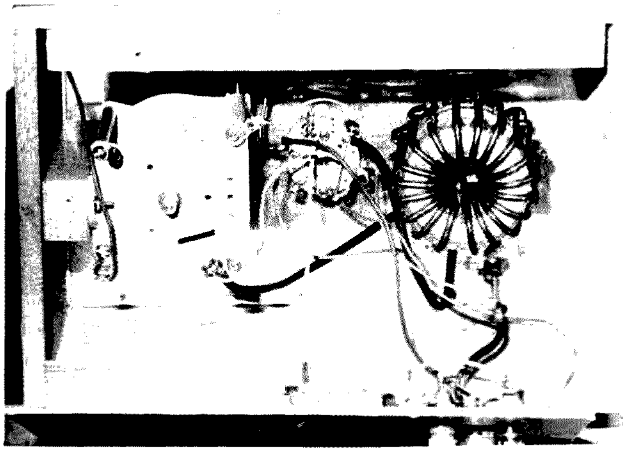
The rig ready to travel in its suitcase.



The rig set up in San Diego and on the air.



Inside of the Matchmaker. Note the fiberglass insulator under C1.

rubber compound placed at points where there might be arcing to ground.

The final circuit has four configurations and a bypass position. It will match high impedances, low impedances, work as a series tuned circuit, and as what I call a tapped circuit. Fig. 1 shows the individual circuits available, while Fig. 2 shows the complete unit. Note the amount of wiring on S-2, the function switch. This is the heart of the matcher, and it is a lot easier to build if the switch is wired prior to being put into the cabinet.

The cabinet is about 250x175x140 mm (7x9x5½ inches), and is made from compressed material with an imitation wood grain surface. The front panel is grounded to the coax sockets to prevent hand effects. Obviously this cabinet offers no shielding, and a search with a wavemeter around the operating unit shows strong rf fields around the coil and switch S-2. Even so, when feeding antennas through coax, when the coax is grounded at the far end, there have been no problems with rf on the equipment.

Operating the Matchmaker is somewhat different from using the Matchbox. I use an external swr indicator, which is inserted between the rig and the tuner. Peak the exciter, dip the final, and adjust first the inductance (switch S-1), then the capacitance for minimum reflected power. It may be necessary to re-dip the final, as the tuner has some effect on PA tuning. Continue adjusting the tuner for minimum reflected power until satisfied. In some configurations there will be a nice dip in swr, but it will be accompanied by an equal dip in forward power! This is easy to detect, and means that the wrong circuit is being used. Just set S-2 to a different configuration and try again. If in doubt, the series circuit will always get some kind of a match, while the "tapped" position will match whatever the others won't.

An "L" match circuit works best into a high impedance load. To get this it's necessary to use a wire about 35 to 40 meters long for all band operation. I have used a 19 meter wire, but matching was difficult.

Feeding this type of an antenna is problematical. If a single wire feed is used you'll have rf all over the shack. So I use coax. While this sounds like some kind of heresy, it works. In fact, a couple of recent articles have pointed out the advantages of feeding with coax. If RG-8 is used, then the loss in any reasonable length will be insignificant. Even RG-58 can be used for short lengths. Of course I'm talking about 100 or 200 Watts of rf, not a full gallon (if you want to melt coax, that's your business).

The photographs show the completed tuner, inside and out, and details of the coil and switch S-2, as well as the traveling setup in and out of the suitcase.

Air travelers: Be prepared for some delay if you carry the rig aboard the plane. The ladies who work the fluoroscopes almost faint when they x-ray a ham radio set! ■

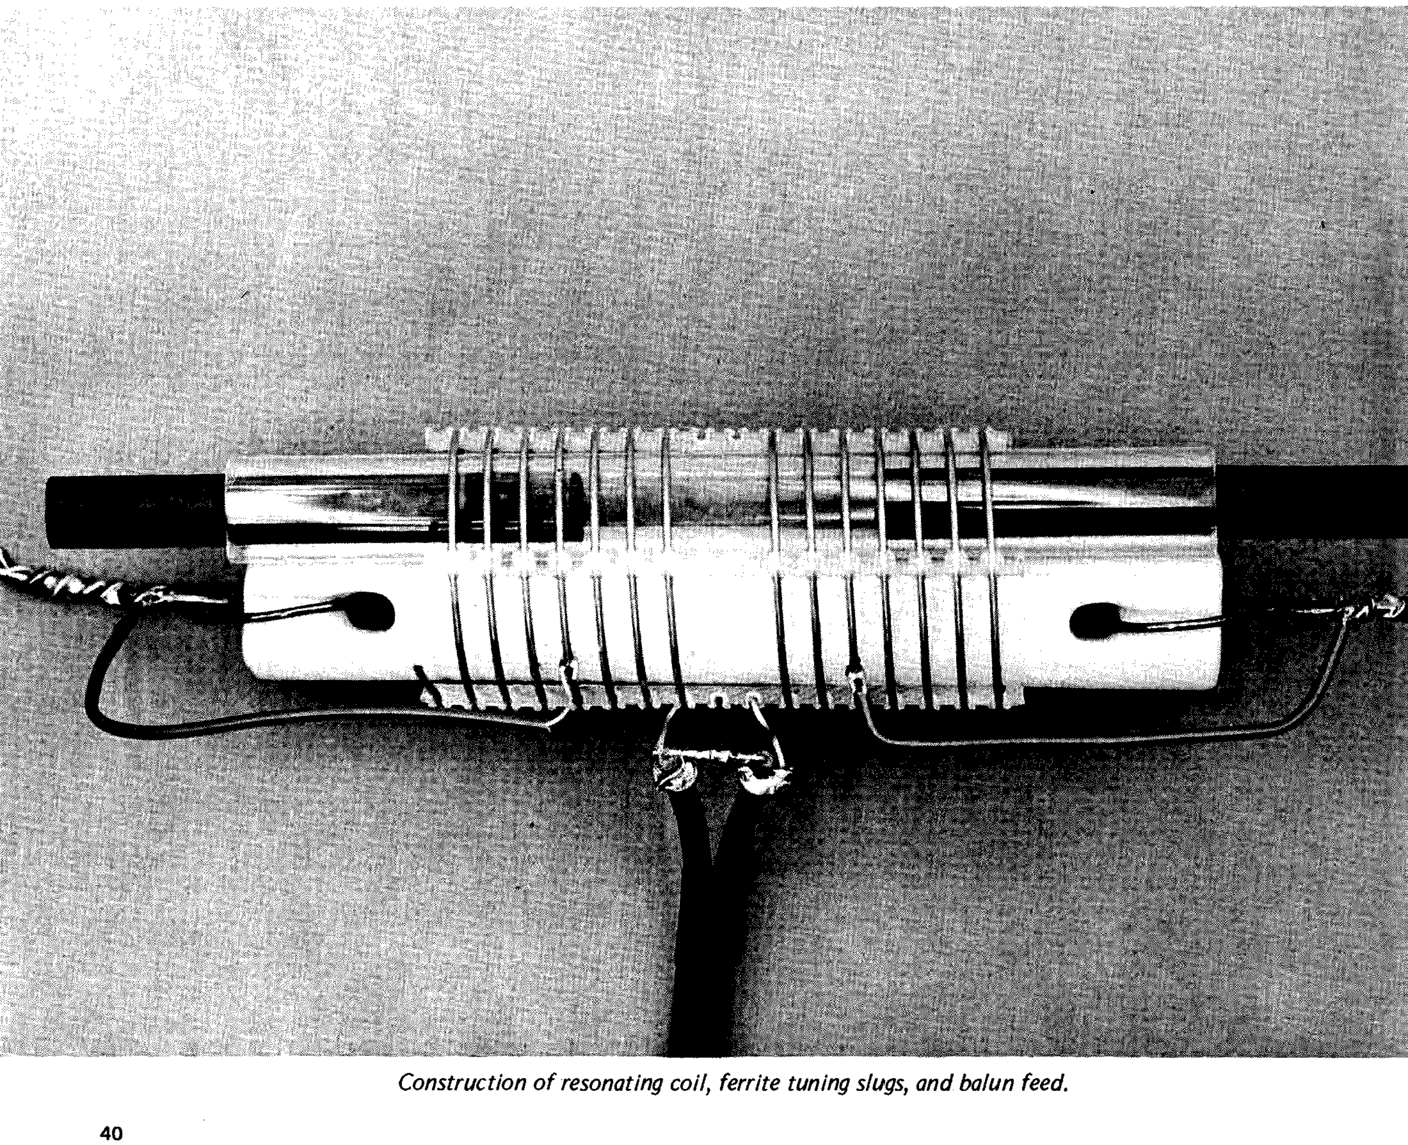
How to Coax Your Antenna

Modern amateur transmitters are designed for a 50 Ohm unbalanced feedline. The classic basic dipole antenna wants to be fed with a 73 Ohm, balanced feedline. The object of this article is to describe the design of an antenna and feedline that simultaneously satisfy the requirements of the transmitter and the antenna.

Reducing the radiation resistance of the antenna from 73 to 50 Ohms only requires a reduction in antenna length. The literature[1,2,3] on antenna theory is in good agreement and predicts a half length from 0.207λ to 0.231λ, depending upon antenna diameter and end conditions. A length of



Construction of resonating coil, ferrite tuning slugs, and balun feed.

0.210λ is recommended to yield a shorter antenna and a radiation resistance of not more than 50 Ohms.

Reducing the antenna length also moves the antenna away from resonance and introduces a capacitive reactance in series with the radiation resistance. In order to restore resonance in the shortened antenna, an inductive reactance equal to the antenna's capacitive reactance must be added in series with the antenna. This resonating inductance is sometimes called a "loading coil." The literature shows that the capacitive reactance is very sensitive to changes in ratio of antenna diameter to wavelength. For a 0.210λ antenna, the capacitive reactance ranges from 34 to 230 Ohms, with 120 Ohms representing an average wire antenna.

Fig. 1 shows a configuration of the proposed antenna: radiating elements cut to approximately 0.210λ, two symmetrical variable inductors and a balanced 50 Ohm feedline.

Cutting the antenna to length is easy, but obtaining the variable inductors takes some care. The photo shows my approach to this problem. The inductor is made from B&W coil No. 3029 with two turns removed in the center. The coil is slipped over a Johnson No. 136-107 antenna insulator. A piece of plastic tubing, 0.75" OD x 0.50" ID x 7", is also squeezed inside the coil to support the two tuning slugs. These slugs, Amidon 12.5 x 100 mm ferrite rods, are used to tune the inductors to resonate the antenna. The range of tuning is large, from 2.0 to 3.75 μH for each coil. The coil is tapped to place the antenna resonance within the tuning range of the slugs. The coil and slug combination, as shown in the photo, can be used to resonate an antenna with a half length of 0.210λ for the 80 through 10 meter bands. If the two turns had been left in the center of the coil, it would also cover 160 meters.

Tuning of the antenna is done at this stage, prior to installation of the feedline, by coupling a grid dip meter to the antenna through a small one turn loop soldered across the feed points. With the antenna as high as possible, adjust the two

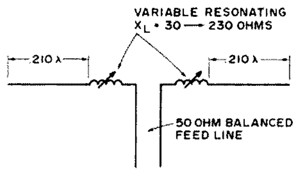


Fig. 1. The shortened, 50 Ohm impedance, resonant dipole.

ferrite slugs *equally* to resonance. To measure resonance of the antenna in its final position, couple the grid dip meter and its one turn coil to the antenna feed point by means of an open wire line. This line *must* be electrically ½λ exactly, or multiples thereof, as measured with the grid dip meter; 300 Ohm twin lead is fine for this measurement. The resulting high standing wave ratio does not affect the measurement of resonance.

Now that the antenna has been designed, built and resonated, the next task is matching its balanced 50 Ohm impedance to the unbalanced 50 Ohm impedance of the transmitter. A device to do this is known as a "balun," a contraction for balanced-to-unbalanced. The amateur literature has numerous references for the design and construction of transformer-type baluns. These balun transformers have very large bandwidths and are particularly effective when used as interstage couplers. However, they are *not* effective for antenna applications unless the coax shield connection of the transformer is at true rf ground potential, such as the one described by Sevick[4]. Imagine an antenna with a transformer-type balun located at its feed point. This point is high in the air, and far from rf ground. If the antenna is ever so slightly unbalanced, this will be reflected across the transformer to the coaxial feedline and cause antenna currents to flow on the outside of the shield; this current results in radiation, which couples to the antenna increasing the unbalance, which increases the feedline radiation, etc., etc. Unfortunately, this antenna feedline interaction is not self-stabilizing towards the balanced configuration; if it

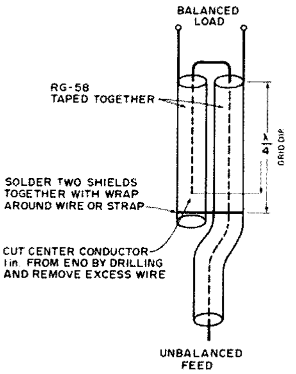

Fig. 2. Schematic representation of 1:1 antenna balun.

were, there would be no need for a balun.

The proposed balun design was first described by Roberts[5] in 1957, but has not been presented in amateur publications. Fig. 2 shows a schematic representation of the balun; some of the details are visible in the photo. From the antenna's viewpoint, it is being fed by two equal conductors in a balanced feedline configuration; from the transmitter's side, it looks like an unbalanced 50 Ohm load, the transition taking place over ¼λ length of the balun. Note that this balun is ground independent and that radiation interaction between the feedline and the antenna elements is prevented by the equal and opposite current flowing in the two outer shield feedlines. The line from the balun to the transmitter will be electrically flat and can be any length. The reader can use reference 5 for the theory, construction details, and measured performance of this balun.

This article has described the design of a dipole antenna and balun that matches an unbalanced 50 Ohm line. The design procedure is valid for parasitic arrays as well as the simple dipole. The performance of the antenna-balun combination has been found to be very good, and it behaves very close to theory. I will not describe performance by means of the conventional swr vs. frequency plot because without very detailed and accurate descriptions of the test antenna (length of feedline, loss characteristics of feedline, conductivity and diameter of antenna, harmonic content of test signal, accuracy of swr meter, etc.) these curves have little value.

The builders of this antenna and/or its balun will enjoy:

- quick and easy tuning to resonance
- low swr at resonance
- minimum feedline radiation
- improved radiation patterns (F to B, gain, and direction)
- reduced harmonic radiation
- ground independence ■

40m DXing -- City Style

Until recently, I thought that vertical antennas approached the ideal for forty meter DX contacts, in terms of signal strength and reasonably low costs. This judgment was based upon the usual city lot antennas, combined with a typical ham's budget. The experiments of Dave WA8TNO proved otherwise. Let me first briefly describe these.

Dave's property consists of two and one half acres. The surrounding land is flat, almost treeless, only a few well-spaced houses. His verticals consisted of two well-matched, quarter wave elements made from aluminum downspouting. Both elements were spaced one half wavelength apart for forty meters, with 180 degree (broadside) phasing. Each vertical element had 120 quarter wave insulated radials lying on the ground and equally spaced around. The earth in this part of northeastern Ohio is "usually moist," and consists of a loam and clay mixture. I believe that these are fairly good conditions for a land-based vertical system. It worked very well.

The single triangle element consisted of small gauge wire, with a total length of about one wavelength. The apex was supported at the 55 ft. level on an existing metal tower. Both lower corners went to ground stakes, and the bottom side was about 12 ft. high over the earth. This was fed directly, without a balun, with coax. The triangle's broadside "pointed" in the same directions as that of the vertical broadside array.

This hastily-erected triangle element had much lower noise pickup, and gave stronger signal reports most of the time. Working Asia and Australia became a regular routine. In a word, the triangle was superior.

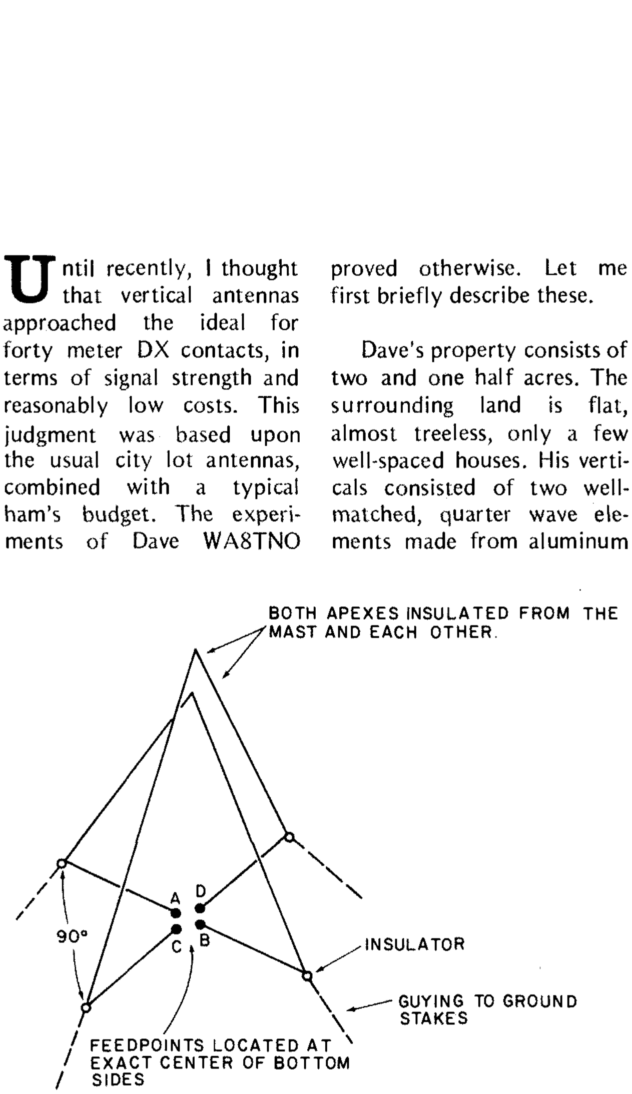

Fig. 1. 40m DX triangle antenna system. Each side = 45.5 ft. Total length of each triangle is subject to trimming for low swr at 7.100 MHz. Elements are #12 copper wire.

City Lot DX Version

Naturally, this old vertical lover wanted to try this on a 50 ft. wide city lot, virtually surrounded by power and phone lines, high trees and aluminum-sided houses in all directions. I ended up with Figs. 1 and 2, after the conclusion of my own testing that used my (then) existing half wave vertical for a comparison.

I wanted some control over switching directions and nulls. My switching scheme in Fig. 2 is not original, but it works well. I used a Kurman[3] double-pole, double-throw rf relay with a 12 V dc coil. Surplus rf relays are fine if you can find them. The .01 uF ceramic capacitor across the relay coil is for stray rf protection. The relay is mounted in a black plastic "electronics" box from Radio Shack, and bracketed to the mast *above* the feedpoint. All

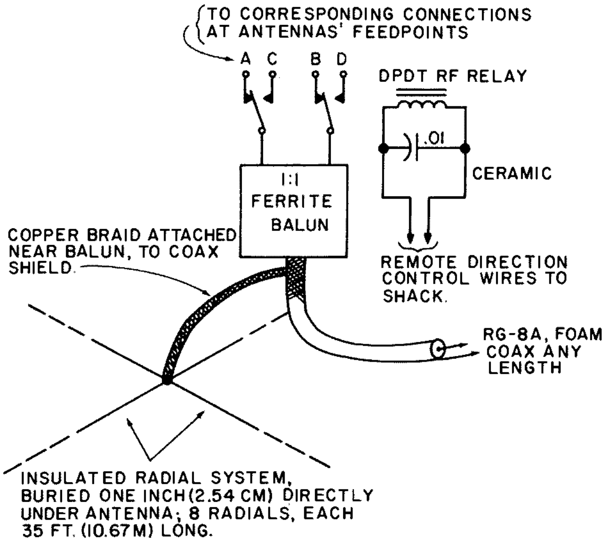

Fig. 2. Direction switching and feed systems.

connecting and control leads are routed through the box's bottom to keep out rain. Try to keep the two sections of feeder between the antennas and relay contacts reasonably short. Most important, make sure these same short sections are the same lengths and spacings to keep the swr constant.

The radials are not an absolute necessity. This antenna system worked well without them. However, *with* the radials the DX stations seem to be stronger more often. The 1:1 ferrite balun broadened the response, with very low swr out to the band edges.

I used #12 gauge enameled hard-drawn "antenna" wire for the antenna elements to help keep down the overall rf losses. Radiation resistance will do you more good than ohmic resistance!

Suggested apex supports can be an existing tower or tree. I used a 50 ft. telescoping TV mast. The actual extended height is 48 ft., with the insulated apexes attached near the top. Bottom height is 8 ft.

Results

DXing from a city lot on 40 meters has finally become a real pleasure for me. Much of it has been easily worked. Getting through pileups is normal when running against the ordinary antennas encountered on this band. Perhaps the most pleasing aspect is getting comparable or sometimes better signal reports than some of the fellows using beams! My rig is solely an FT-101 with no high power attachments.

Conclusion

City lot dwellers, let's take down those ordinary urban antennas, and quit being "trapped" in our thinking. Now is the time to put up a *real* antenna. You too can have a respectable 40 meter signal, as well as some of our country cousins — and with a lot less grass to mow than they have! ■

The Secret 2m Mobile Antenna

It may be difficult to accept, but there are many amateurs who are not interested in repeater operation. But, almost all amateurs recognize the unique communications capability that 2 meter repeater usage can provide, especially in the case of some emergency while mobile. This article describes a matching/isolation network that will allow one to use a regular auto antenna on 2 meters without interfering with the normal operation of the auto's AM or AM/FM radio. No relays or other type of switching is involved. One can leave the network connected to a 2 meter transceiver installed in the car or just bring it out to a BNC jack installed in the car. Then when a portable transceiver is used in the car, it can be plugged into the antenna system.

The performance of an auto antenna along with the matching/isolation network will normally not equal that of a rooftop ¼λ whip or similar antenna. But, no holes have to be drilled, extra antenna mounted, etc. The losses involved will vary from situation to situation, but should be low enough so adequate communication can be achieved over a local repeater with a few Watts of output power.

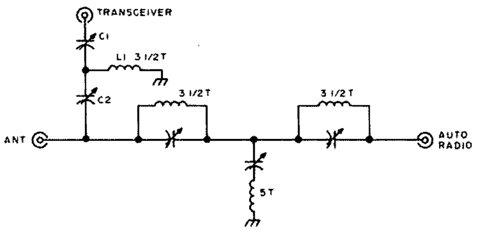

Fig. 1. Matching/isolation network. All capacitors are 27 pF trimmers. Coils are approximately ¼" diam., ½" long, of #16 or #18 wire with turns as indicated.

What is needed in a matching/isolation device is a matching network between the transmitter and antenna which will match impedances and also simultaneously act as a high-pass filter. Also, what is needed between the antenna and the auto radio is a filter to attenuate 2 meter energy only from getting into the radio. Both these functions are accomplished by the circuit of Fig. 1. The T network of C1, C2 and L1 performs matching and acts as a high-pass filter. The rest of the components act as a rejection filter tuned to the 2 meter transmitting frequency. They can be viewed as individual tuned circuits – 2 parallel resonant and one series resonant.

The entire network should be placed in a shielded enclosure and as close to the base of the auto antenna as possible. But, it will also work if placed at the end of the auto radio's transmission line (at the auto radio's antenna input jack), but with greater losses, of course. Wherever it is placed, however, the auto antenna's extended length and the length of transmission line used to reach the antenna should remain unchanged after the network is tuned. Auto antenna lengths which produce low base feed point impedances are best, such as ¼λ (20¼") or 5/8λ (50½"), but other lengths can be used. A length greater than 50½" should not be used since high angle radiation will increase sharply.

One can either crudely tune the network up and let it go (if communication can be established) or attempt to tune it up for overall minimum losses. In any case, a bench check should first be made with a grid-dip meter. Short all the input/output points. Then resonate the C1, C2, L1 circuit (by coupling to L1) for resonance about 2 MHz below the transmitting frequency. After installing the network in its operating location, re-adjust C1 and C2 for maximum field strength reading.

If you want to tune up the whole network more properly, an swr meter has to be inserted in the transmission line to the auto antenna. Leave the output terminal to the auto receiver connected. Adjust C1, C2 and L1, if necessary, for the lowest swr. With an odd length of transmission line, it might even be necessary to add some inductance in series with C2 for lowest swr. Then connect the swr meter in the line to the auto receiver and, using only the "forward" or "set" reading, adjust the trap trimmers for a minimum reading. One then has to go back and forth several times with the swr meter in each line to compensate for the detuning effect of each adjustment on the network.

When carefully adjusted, one can *simultaneously* use the auto antenna for 2 meter communication and AM or FM reception. ■

An Inverted Vee for 160/80m

John Skubick K8ANG
1040 Meadowbrook
Warren OH 44484

City lots and bank accounts have something in common for many of us. Both tend to be small! Here is a cheap antenna system that covers both 80 and 160 meters, but is the size of an 80 meter "inverted V," with *no* ground radials. If your city or suburban lot is typical, you'll barely have room for one 160 meter radial, let alone several!

On 80 it is an inverted, folded dipole. The feedpoint impedance is less than 300 Ohms because of the inverted shape. For 160 it becomes a half wave inverted dipole, with the ends folded back toward the middle, and "end fed." The feedpoint impedance now becomes very high. The flat top portion can be constructed from transmitting twinlead, TV twinlead, or 300 or 450 Ohm TV open wire. You can even make it out of ordinary "antenna wire" if the parallel wires are spaced up to 6 inches. The length is approximately 70 feet for *each leg.* More on leg length later.

Since both bands utilize the same feedpoint, we must have a simple and effective feeder system for both bands/impedances as follows:

Without a Tuner

Two baluns are required at the shack end of the feed line. A 4:1 for 80, and a 1:1 for 160. I used two Amidon[1], "$5.00 balun kits." I put two layers of plastic electrical tape over each core for better "arc-over" protection. Both baluns were easily wound within 30 minutes, per enclosed instructions. Use 36 inches of wire for each winding, leaving about two inches extra for lead connections. I put each balun into a 34¢ plastic, screw-lid, freezer container, with a coax socket attached. All possible openings were then generously sealed with a tube of G.E. Silicone Seal, sold by blister-pack in most hardware stores. Amidon's spec sheet states, "80-6 meter operation." However, these baluns seem to work just fine on 160 as well!

Use RG-8 between the balun(s) and the transmitter. The feed line between the balun(s) and antenna should be "300 Ohms" type such as twinlead, or better yet 300 Ohm, TV, open wire "ladderline" for higher power handling. The dimensions for the balun-to-antenna feed line are 110 feet for solid dielectric twinleads or 130 feet for the open wire line.

Initial tuneup begins with 80 (or 75) meters, for your favorite section of the band, by trimming the ends of the flat top equally, a couple of inches at a time, for minimum swr (measured at the transmitter). A neat "trick" is to trim it for "75 phone," then hang clip-on single wire outriggers for "80 CW." Minimum swr will be about 1.5:1, using the 4:1 balun. Since the antenna is inverted and close to ground, the feeder is "seeing" less then 300 Ohms from the folded dipole.

Next is the 160 meter tuneup. Change over to the 1:1 balun. Now, trim the twinlead (or open wire) feed line for minimum swr in your favorite portion of 160. You can get this down to 1:1. That's it for "tunerless" operation.

With a Tuner (Antenna Coupler)

It's easy for you tuner lovers. From my experiments, it appears that the leg length can vary between 60 to 70 feet with no reduction in performance, for either band. Your coupler will "tune" this antenna and feeder system over the entire 160 and 80 meter (and 75) bands.

You have a wider choice of feed lines also. You can use TV and transmitting twinleads, 300 and 450 Ohm TV open wire "ladderlines," or even home brew openwire line. The length of balanced feed line, between the antenna and your coupler, may load easier if it is about 90 to 120 feet for the solid dielectric types, or 120 to 140 feet for the open wire types.

For the antenna coupler tuneup, first preset your transmitter's "tuning and loading" controls, by loading it directly into a 50 Ohm dummy load. (You *do* have a dummy load, don't you?) Now, switch the transmitter into the coupler. Do not touch the transmitter's "tuning and loading" con-

trols, because they are now preset for 50 Ohms. Do your tuning and loading with the coupler, which will transform whatever impedance and reactance is appearing at the "shack end" of the feed line into 50 Ohms for your transmitter. If you are a tuner fancier, and have read this far, chances are you already have a coupler for 80 meters and the higher bands. Fig. 2 shows a compatible type of coupler for 160.

Antenna Supports

I used a 50 foot, 5 section, telescoping TV mast to support the apex. Actual extended height is 48 feet. The mast is hinged at the base, by driving two 3 foot x 2 inch pipes into the ground about 3 inches apart. I drilled a hole into each pipe, so that a suitable large bolt could be passed through both pipes and the existing hole at the base of the mast.

The antenna supports the mast in the east-west direction. Two lengths of non-metallic clothesline also support the mast from the top, but in the north-south direction. No center guys were used.

The insulator ends of the antenna, and the ends of the clothesline, are attached to 5 foot x 1½ inch pipes driven 3 feet into the ground.

The entire assembly isn't too heavy. It couldn't be, if skinny, stringbean-physiqued K8ANG has to lift it up and walk it into the vertical position!

A tree and a halyard can also be pressed into service for the center support. My trees are never properly located.

Results

It certainly gets the rf out of my backyard! On 80, the performance is exactly that of a "regular" ½ wave inverted dipole, using the same height, center

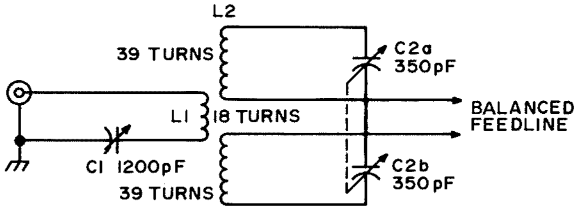

Fig. 2. 160m antenna coupler. L1-L2: Illumnitronic 2410 or Polycoils 1780, 10T/inch, 3 inch diam. C1: Three section "broadcast" type, all sections paralleled. C2: 200 pF per section may be used with 100 pF in parallel. Note: Do not ground any portion of L2 or C2 – leave them "floating" above ground on insulators.

supported. It also seems to be more broadbanded. On 160 I have worked coast-to-coast, and Canada easily, using a barefoot Japanese transceiver. I cannot compare it to a full size inverted dipole on 160, because this would be twice the size of my backyard!

Conclusion

There have been many 160 and 80 meter antenna articles written these past few years. Not all of them will fit everyone's backyard or performance specifications. Maybe this one will help to "fill the void" in your city lot antenna farm. ■

The Dipole Dangler

About ten years ago, the Summer Institute of Linguistics (SIL) here in Brazil was granted permission to use radios for communication between our centers and remote Indian villages. SIL is working here and in other countries with people who speak some of the more than 2000 unwritten languages of the world. Our purpose is to learn these languages, analyze them, teach the people to read and write their own language, and translate the New Testament for them. Here in Brazil, the linguistic-translation teams live in the Indian villages for periods of from about three to six months at a time, taking a radio with them each time to maintain contact with one of our five centers. We are using the Stoner SSB-20A radio, an excellent portable with about 15 Watts PEP output, powered by any 12 volt source including dry cells. The antennas are dipoles about 86 feet long. Communications distances range from about 100 miles to over 500 miles.

Because of the importance of the radio communications and because the equipment has to be set up and taken down each time by non-technical personnel, one area of potential problems was the antenna system. The antennas had to be reliable, rugged, and easily handled. Because more than 40 stations were involved, they also had to be inexpensive and made from readily available materials. The purpose of this article is to share some of our experience with you with the hope that some of the ideas might prove useful to you for your home station antennas, or for portable antennas for field day use, etc.

The construction of the center insulator is a very important factor in building a reliable dipole antenna. Purchasing a commercial unit was not practical for us because of cost and also the delay in obtaining it. The center insulator we have been using consists of a standard porcelain insulator to which is attached a piece of ¼ inch plastic in the form of a cross.

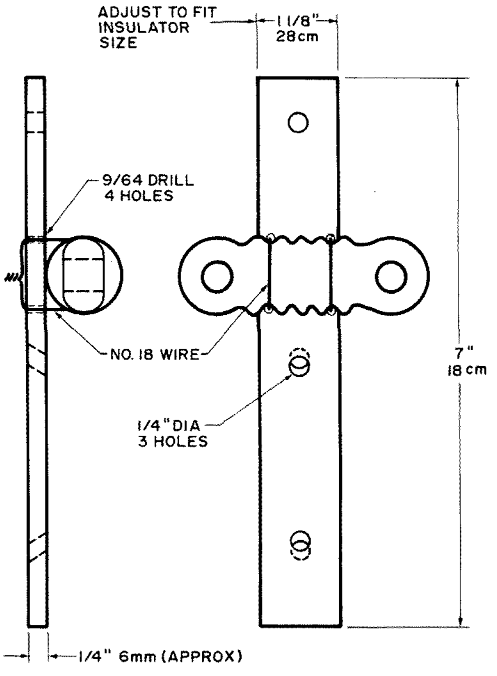

Fig. 1. Center insulator.

See Fig. 1. The porcelain insulator provides the necessary strength, and the plastic gives support to the coax cable. The plastic is attached to the insulator with No. 18 solid copper wire, wrapped twice around the insulator and twisted together in back of the plastic. Three holes are drilled in the plastic to support the coax cable.

We have been using flexible, bare-copper antenna wire, and this has proved very adequate. To attach the wire to the center insulator, pass the wire through the hole twice and wrap the end around snugly for a distance of at least three inches. Attach both legs to the center insulator and attach the end insulators in the same way. Do not solder anything at this time. Before going any further, wrap the antenna legs on wooden forms as described below. This makes a neat package to take into the shop to attach the coax cable.

Cut the coax cable to length, unless you want to wait and install the antenna first. Pass the end of the cable through the holes in the plastic, starting from the back as shown in Fig. 2. Remove about 12 inches of the plastic jacket. Remove the center conductor from the braid by pulling it through the braid. Do not comb out the braid.

Use standard vinyl tape cut to about 3/8 inch in width to seal the point where the center conductor leaves the braid. Seal this junction very carefully. After the antenna is completed, we also seal this further with Q-dope or epoxy cement to make it as watertight as possible.

Pass each of the conductors (center conductor and braid) through one of the holes in the center insulator, drawing the braid side tighter than the other so that it will take the strain. Pass the braid through a second time and wrap it over the antenna wire,

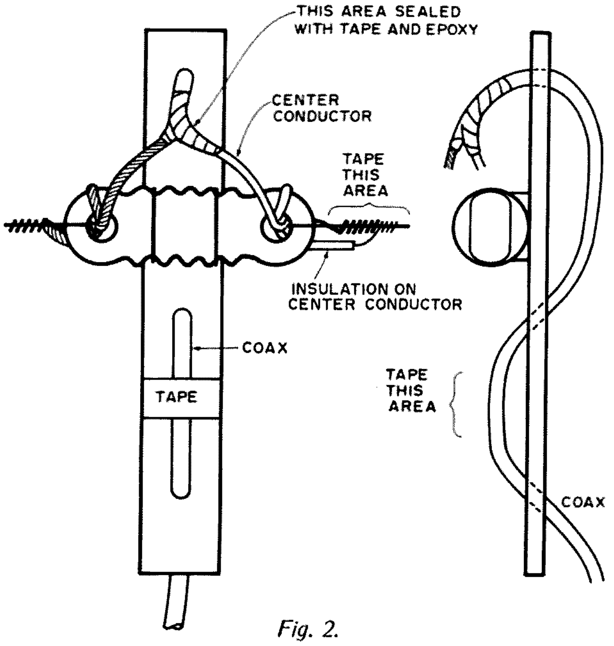

Fig. 2.

in the same direction as the original wrapping. Solder the braid to the wire in the middle of the wrapping, leaving the rest free to flex.

Pass the center conductor through the hole a second time and lay it alongside the wrapping on the antenna wire. Mark a half way point on the wrapping and strip the insulation to this point only. I have found it very easy to strip the insulation from coax by scoring the insulation with wire strippers every ¼ inch or so and then crushing the insulation with long nose pliers to break the adhesion between it and the wire. After this, the insulation comes off relatively easily. Once the wire is stripped, wrap it around the antenna wire a few turns. Do not tin the wire if it is stranded. Solder the center conductor to the antenna wire, making sure that the antenna can be pulled straight without straining the coax inner conductor. Solder only where the conductor attaches to the antenna wire. Reinforce the entire connection by wrapping vinyl tape securely around both the inner conductor and the antenna wire, starting from the center insulator and extending past the solder joint. This is very important because it secures the center conductor to the antenna leg, allowing a minimum of independent movement and reducing the threat of breakage at what is probably the most fragile part of the whole antenna. Tape the coax cable to the plastic support between the lower two holes.

At this point, seal the "V" in the coax with epoxy cement or other sealer and let it dry. Install the coax plug and the antenna is ready for use.

After the antenna is constructed, care in handling is very important to long life (for the antenna). Many of you know the frustrating tangle that you can have with a long dipole antenna that has been coiled up and then uncoiled improperly. To avoid this, we are using wooden forms made from ¼ inch plywood cut to approximately 5 by 7 inches. Each leg of the antenna is carefully wound on one of these forms to avoid tangling. To use the form, extend the antenna out full length on the ground and carefully check it for kinks. Starting at the end of one leg, carefully wind the antenna on the form by *winding the form onto the wire* while walking toward the center insulator. Do not coil the wire onto the form. Use one form for each leg. When you get ready to re-install the antenna, carefully unwind the wooden forms, leaving the antenna fully extended on the ground. Do not pull the wire from the forms or you will have a kinky mess. Carefully check for kinks or other problems before installing the antenna.

Multiple frequency antennas can be made using a modified center insulator as shown in Fig. 3. Spacers for separating the antenna legs can be made from 3/8 inch plastic electrical conduit, or the second antenna can be in the form of an inverted V. In this case, the antenna will need to be five per cent longer than a normal dipole.

Using this method of construction and using the wooden forms for handling the antennas, we have had a minimum number of problems with our antennas during these past years. ■

Amateur Weather Satellite Reception

One of the euphemisms that is often used to describe the times in which we live is the "space age." The gradual buildup of technology that enables mankind to travel and work in space and to visit other worlds has resulted in a whole new age of exploration as we gradually learn more about the larger universe in which we live. Probably no aspect of the space program has a greater effect on our lives than the tremendous strides in weather satellite technology. To many, such satellites are merely the "eyes in the sky" that serve to amplify the weather map on late night news, but they are far more important than that. They have contributed to new standards in weather forecasting and provide an early warning system that has saved uncounted lives and dollars by providing advanced warning of destructive tropical storms such as typhoons, cyclones, and hurricanes. Mapping of snow and ice cover is still another spin-off from this useful program. At the time this article is being written there are seven operational U.S. weather satellites in orbit around our planet continuously scanning the ever-changing weather patterns that affect our lives.

It is now a decade since Wendel Anderson K2RNF first showed how it was possible to receive and display pictures from such satellites (2) and with today's technology the job is far easier than it was just ten years ago. With far less financial outlay than that required for even a modest sideband station it is possible for amateurs to receive and display pictures from most of the operational satellites, while for someone who is really hung up on the subject none of them is out of reach. The purpose of this article will be to describe the status of the various satellite systems now in use and to provide numerous references for the construction of home satellite receiving stations. Such stations can provide daily glimpses of the world from space which few of us would ever see and are an interesting entry into the world of meteorology. The low cost of such ground stations make them attractive to small educational institutions where they can provide practical data for courses in weather and the earth and planetary sciences as well as providing worthwhile class projects in electronics.

There is certainly no "one way" to put together a satellite station – there are a multitude of options, each varying in terms of cost, operating ease, and system flexibility. I will discuss the various requirements for satellite ground stations and provide references from the widely scattered literature on the subject so that you can do some background reading on the kind of system you might like to set up. Some of the options are essentially jury-rigged affairs of casual interest but others can, at low cost, provide performance comparable to commercial or government installations. Ever since entering the weather satellite game amateurs have distinguished themselves by continually developing better ways to accomplish various tasks, usually far exceeding professionals in terms of the cost-quality equation. Amateurs, with their knowledge of electronic and communications systems, are often among the first to spot problems with operating satellite systems and thus provide a valuable service in monitoring these satellites. Weather satellite technology represents a very concrete example of how "amateurs" can make a significant contribution to space age technology. Why not give it serious thought – you are certain to have lots of fun and may

	APT Mode	SR Mode
Subcarrier Frequency	2400 Hz	2400 Hz
Subcarrier Amplitude:		
White	Maximum	Maximum
Black	Minimum	Minimum
Line Rate	240/minute	48/minute (present) 120/minute (future)
Frame Time	200 seconds	Continuous
Lines Per Picture	800	Depends on length of pass
Video Bandwidth	1600 kHz	450 Hz (IR) 900 Hz (visible)

Table 1. Characteristics of the video format of the APT and SR modes.

Name	Frequency (MHz)	Period	Inclination	Mode	Products
ESSA 8	137.62	114.7 min	101.5°	APT	Daylight real-time cloud cover pictures
NOAA 3	137.5 (primary) 137.62 (test)	116. min	102°	SR	Visible and infrared cloud cover pictures in daylight, IR cloud cover pictures at night
NOAA 4	Same as NOAA 3	115.0 min	101.7°	SR	Same as NOAA 3

Table 2. Polar orbiting weather satellites.

make some major contributions at the same time!

Satellite Picture Modes. The two video modes of greatest interest to amateurs are highlighted in Table 1. Both modes utilize a 2400 Hz audio subcarrier to transmit the video information. Subcarrier amplitude varies from maximum for white picture areas to minimum (approximately 4% of maximum amplitude) for black picture areas. Subcarrier amplitudes between these two extremes represent varying shades of gray. The two modes differ however in the line rate and picture organization. The first, the APT mode (APT is an acronym for *A*utomatic *P*icture *T*ransmission), transmits video lines at the rate of 240 per minute or 4 lines per second. A single picture or "frame" requires 200 seconds for transmission, resulting in an 800 line picture. The baseband video bandwidth of the system is 1600 kHz, so if audio filters are used to help remove noise from the satellite signal they should be centered on 2400 Hz with a 1600 Hz bandwidth. Narrower filters will result in progressive loss of picture detail. The 800 line APT picture is far sharper and has much greater resolution than a typical TV picture display.

The second mode – the SR or *S*canning *R*adiometer mode – is based on the use of a mechanical scanning system on board the spacecraft. As the satellite moves along its orbital track a mirror scans the earth beneath in a narrow beam at right angles to the satellite's orbital track. Present SR systems use a 48 line per minute scanner. The SR system is capable of providing both visible light and infrared (IR) images of the earth below. The IR data occupies the first half of the scanning line with the visible data inserted from a tape loop during the second half of the line when the satellite scanner is scanning up against the spacecraft. The SR data format can be considered as a 48 line per minute system with half the line being IR data and the other half visible data, or it can be treated as a 96 line per minute system of alternating IR and visible data lines. Display systems can be designed around either option. The SR picture is not broken up into discrete frames as it is in the APT mode – instead transmission of picture data is continuous as long as the spacecraft is in range with the vertical "scanning" provided by the movement of the spacecraft along its orbital track. Present systems utilize a 48 line per minute scanner but in 1978 a new SR system utilizing a 120 rpm scanner will be inaugurated. The principles of operation are identical to the 48 line system except that the pictures will be several times better in resolution. Various display systems for 48

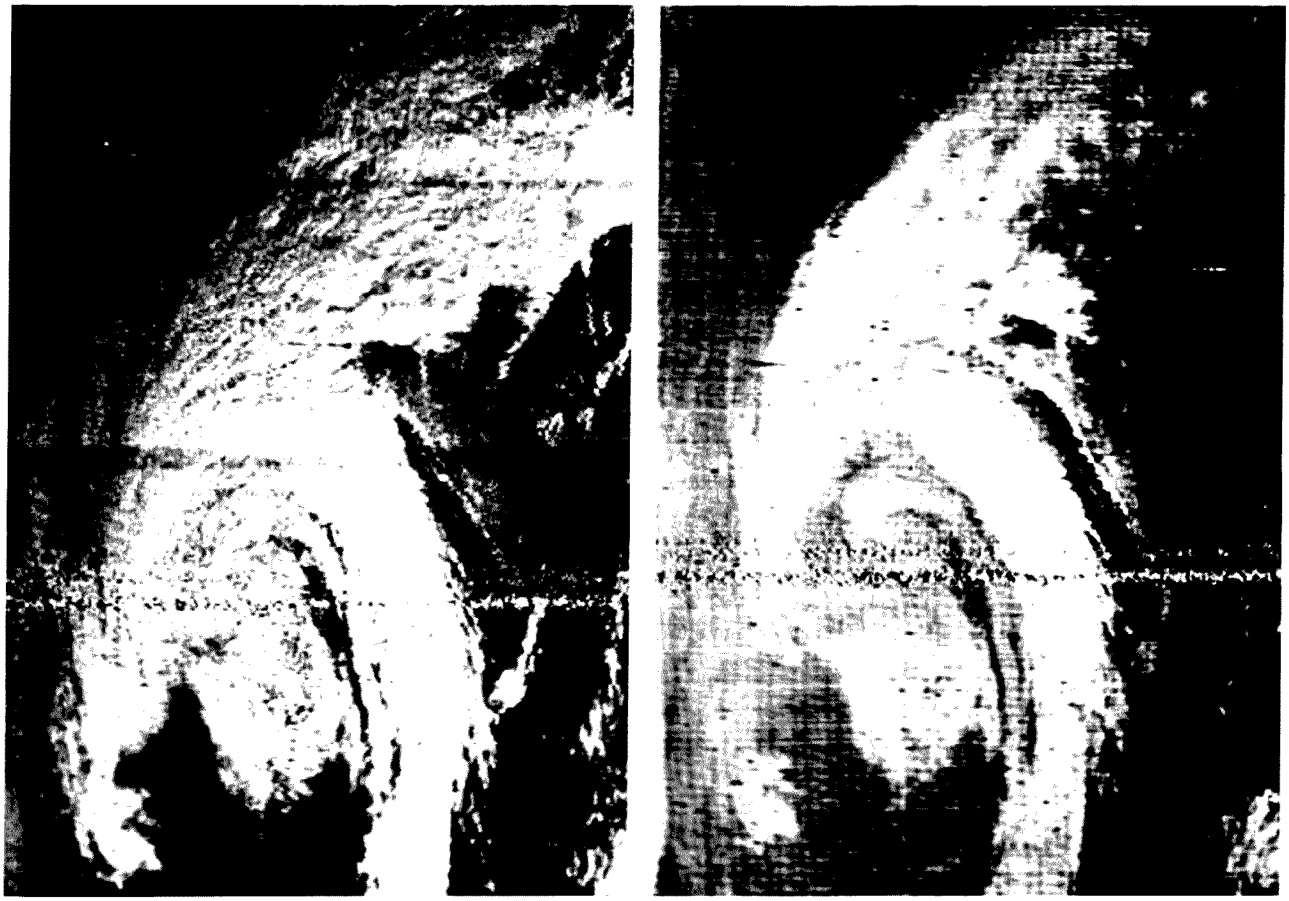

Photo 1. Visible light (left) and infrared (right) readout from a single NOAA 4 pass over eastern North America on 20 November 1975. The differences in the two views, which represent the same area as seen at the same time, are due to the characteristics of the visible and IR imaging systems. The visible channel sensors respond to light in much the same manner as the human eye, and all cloud structures are shown where sufficient light exists. The upper right portion of the visible view (northwest) is dark because of low sun angle at high northern latitudes at this season and time of day (early morning). The IR channel responds to heat, with the lightest areas representing cold zones and with darker areas progressively warmer. Low clouds do not appear (as they are near ground temperature), while the Atlantic (lower right) appears darker than the land areas to the west because the ocean waters are warmer than the ground at this season of the year.

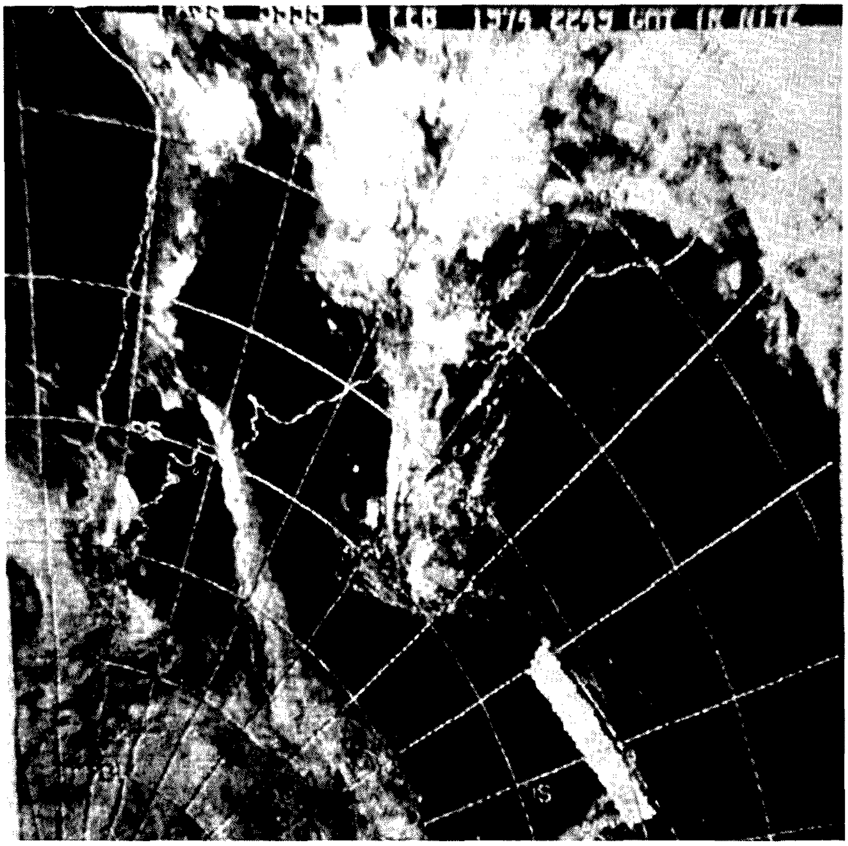

Photo 2. An example of an APT WEFAX transmission from ATS 3. Such computer gridded pictures are put together on the ground from NOAA SR data and are relayed through the geostationary satellite for worldwide distribution to any station within line of sight of the satellite. The view shown here represents ¼ of a polar projection of the southern hemisphere showing most of South America and part of Antarctica. In this case the picture was put together by computer analysis of NOAA IR readout. Grid lines were superimposed and the picture was then relayed through the satellite.

line SR service can be modified for 120 line display with comparatively little difficulty. Baseband video bandwidth for the IR "channel" of the 48 line SR system is 450 Hz while the visible channel bandwidth is 900 Hz. As with the APT mode, if 2400 Hz audio filters are used they should have a bandwidth at least equal to that of the channel in use to get full picture resolution.

Operational Satellite Systems. There are two general types of satellite systems of potential use to amateurs – polar orbiting satellites and geostationary satellites. Each will be discussed separately.

Polar Orbiting Satellites. Polar orbiting satellites, actually in near polar orbits, provide continuous real-time transmission of cloud cover pictures on a worldwide basis. Table 2 summarizes the data on operational polar orbiting satellites. Each of these satellites provides either 2 or 3 useful daylight passes per day within range of a given ground station, and an equal number of night passes. All of the systems provide useful daylight coverage and some provide night pictures as well. ESSA 8, launched in late 1968, is the oldest of the operational polar orbiting spacecraft and is the last of its series. Using a TV camera tube and transmitting APT pictures on 137.62 MHz, this satellite provides as many as three useful pictures on a single pass during daylight hours. The spacecraft is solar powered and is shut down on night sides of its orbit where the TV camera is non-functional. Early in 1975 the performance of camera #1 dropped past the useful level and camera #2 was switched on to replace it. Late that year the camera shutter on the spacecraft began to malfunction – a prelude to total system failure in earlier satellites in the ESSA series. It is probable that this particular satellite may well be shut down by the time this article appears in print and no future satellites of the series are planned.

The primary polar orbiting satellite series now in use and planned for use well into the 1980s is the NOAA satellite series, of which NOAA 3 and 4, operational at the time this is written, are prime examples. These satellites transmit SR pictures at a frequency of 137.5 MHz with monthly one-day tests at 137.62 MHz. Their orbits are essentially identical to that of ESSA and are chosen so that the satellite passes over a given location at about the same time every day. The SR systems aboard these spacecraft provide both visible and IR cloud cover pictures during daylight passes and IR pictures during evening passes. Photo 1 shows an example of both visible and IR data from a single pass. The data display is in the form of a continuous strip of picture material that is received as long as the spacecraft is above the horizon. The examples shown represent about 10 minutes of coverage from the pass in question. Such satellites are ideal for obtaining localized weather patterns, for it is possible to get a direct overhead view of local weather systems and for a single pass the weather pattern for about half of the North American continent – in a strip extending from Greenland to Yucatan – can be obtained for a station located in the north-central U.S. NOAA 4 is currently the primary spacecraft in the series with NOAA 3 serving as a backup. If the orbit of NOAA 3 brings it in conflict with NOAA 4, 3 is switched to 137.62 MHz. NOAA 5 is scheduled for launch in early 1976, at which point NOAA 3 will be deactivated and NOAA 4 will serve as the backup spacecraft if all goes well.

Name	Frequency (MHz)	Subpoint	Mode	Products
ATS 1	135.6	149° W	APT	WEFAX – Satellite predict messages, grey scale, computer gridded cloud cover pictures from NOAA data (western U.S., Pacific, E. Asia, E. Africa)
ATS 3	135.6	69° W	APT	WEFAX – Similar to ATS 1 except coverage centers on eastern U.S., Atlantic, Europe, West Africa, South America
SMS 1	1691	75° W	APT	WEFAX – Computer gridded visible and IR views derived from on board spin scan very high resolution radiometer, pictures sectorized from full earth disc
SMS 2	1691	115° W	APT	WEFAX – Similar to SMS 1

Table 3. Geostationary satellites transmitting weather picture data.

Geostationary Satellite Systems. Geostationary satellites are satellites whose orbital path lies over the equator. The altitude of the satellite is approximately 22,000 miles so its orbital period is exactly 24 hours. Since the satellite orbital period is equal to the period of rotation of the earth the satellite always maintains the same position over the equator. This position is known as the satellite *subpoint.* Since such a satellite maintains the same position over a point on the earth, as seen from the earth it appears to remain in the same part of the sky and hence need not be tracked – the antenna can merely be lined up and fixed in place. The extreme altitude of these satellites means that most of a hemisphere can be viewed from them and they are an ideal camera platform for viewing the full earth disc or relaying signals from a ground station to any station within view of such a satellite. Table 3 summarizes the geostationary satellite systems of interest to amateurs. ATS 1 and 3 (ATS is an acronym for *A*pplications *T*echnology *S*atellite) are both experimental satellites to test the feasibility of hemispherewide radio communications relays for a variety of purposes. One of the ways in which these satellites are used is in the transmission of WEFAX (weather facsimile) pictures in the APT mode. These pictures are transmitted on a frequency of 135.6 MHz on a regularly scheduled basis and include "predict" messages for calculating orbits of the various polar orbiting satellites, gray scale transmissions, and cloud cover pictures. The latter are computer gridded to show lines of longitude and latitude and geographic boundaries. Photo 2 shows a typical transmission of WEFAX data from ATS 3. If both satellites are in range of a given ground station it is possible to acquire cloud cover pictures spanning the entire world. Both of these satellites have been in operation for several years and should they fail they will not be replaced as they are strictly experimental. The WEFAX program, however, will be continued with a new series of geostationary satellites of the SMS/GOES type. The SMS satellites are prototypes of the operational system (SMS stands for *S*ynchronous *M*eteorological *S*atellite) while the GOES satellites (*G*eostationary *E*nvironmental *S*atellite) will be the operational versions. GOES 1 is scheduled for imminent launch as this is being written while SMS 1 and 2 are presently in orbit. These satellites produce extremely high resolution pictures which are transmitted to special ground stations for computer processing. Although reception of the original pictures is still impractical (not impossible, it simply costs too much as yet), the computer processed versions are available, along with other products, as APT WEFAX transmissions. The major drawback of these satellites is that transmission takes place on S band at 1691 MHz. Suitable converters for converting S band signals to the 137 MHz range used for reception of ATS and polar orbiting satellites can be put together from commercial components (8) but such an approach is prohibitively expensive for most of us. The subject of S band receivers will be discussed later. Just to show that the task is not beyond amateur capability, Photo 3 is included as an example of SMS WEFAX reception. This particular picture was received by Roy Cawthon of Atlanta, Georgia, who has the only amateur S band system in operation at the time this is being written. Just to show that amateurs are not lagging behind, Roy's station is one of only 5 in the world at the present time.

All APT and SR satellite transmissions, regardless of frequency, use FM modulation with 9 kHz deviation.

Assembling a Satellite Station. There are very few references that provide all of the information you might require to set up a station from scratch. Vermillion's NASA report (23) describes a long crossed yagi antenna, a tube-type FM receiver and preamp, and a CRT display system with APT capability and modifications for an early type of SR display. Later government publications are available to update SR display for current standards. Kennedy (6) describes a completely up-to-date display system including an FM receiver with a PLL detector to eliminate Doppler effects. The three part article is very complete and is

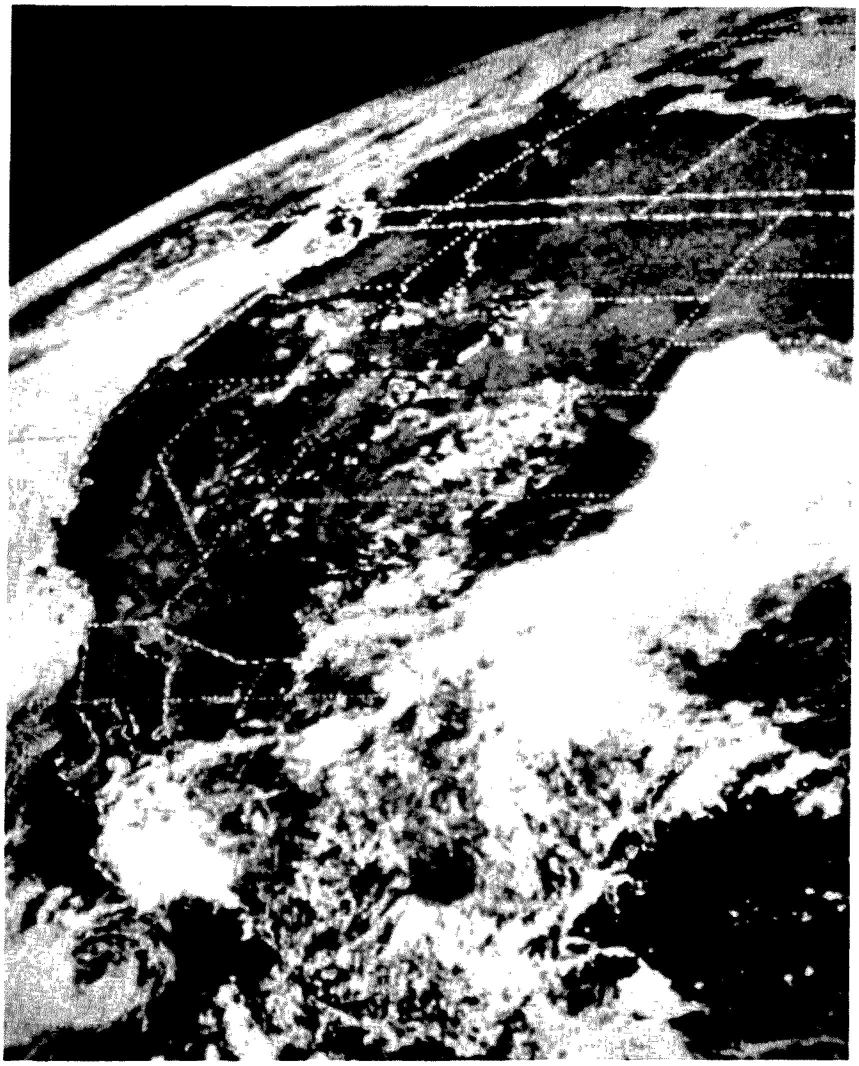

Photo 3. An example of an SMS S band (1691 MHz) WEFAX transmission as received and displayed by Roy Cawthon of Atlanta, Georgia. Such pictures are derived from the very high resolution spin scan radiometer on the spacecraft, which takes both visible and IR pictures of the full earth disc as seen by the satellite. The pictures are gridded on the ground and re-transmitted through the satellite. Operational versions of this series (GOES satellites) will transmit such pictures and a variety of other WEFAX products. The development of effective, low cost S band converters is one of the major challenges facing amateur satellite experimenters.

useful reading if you plan your own system design. The third source (21)[1] is one I am particularly partial to simply because I wrote it! This one book contains all of the information required to construct a complete satellite receiving station including numerous accessories. The construction articles are complete and various options are presented for most system requirements. Chapters include antennas, receivers and preamplifiers, CRT display systems, a FAX system, tracking, digital orbital timers, and ways to completely automate station operations. For those who would like to do additional background reading or who would wish to put together a station based on several different options, the following references, grouped by subject, will be useful reading.

Antennas. ATS or polar orbiting satellite reception requires the use of a circularly polarized antenna with the gain requirements for ATS being somewhat more stringent than for the polar orbiting spacecraft. (9) describes a very simple yagi for manual tracking that is suitable for polar orbiting spacecraft if you have someone willing to stand outside and operate it! (21) describes the construction of a short crossed yagi antenna suitable for polar orbiting satellites and discusses various commercially available antennas suitable for ATS or polar orbiting systems. (23) describes a longer crossed yagi suitable for use with either ATS or ESSA and NOAA spacecraft. (22) includes some interesting ideas on antenna mounting which might prove useful. You will notice the emphasis on crossed yagi antennas for circular polarization. This is simply because they have proved far easier to construct and mount than helix antennas, the other major alternative (3), (7). (3) contains useful design and mechanical data for crossed yagis in the Space Communications chapter.

[1] To be published in early 1976.

Reception of S band SMS/GOES signals requires a dish antenna. NASA recommends a 10 foot dish but Roy Cawthon has gotten by with a 6 foot version. The use of modern low-noise transistors may make possible the use of still smaller dishes in the order of 4 feet. I certainly hope so since my own four-footer is mounted in the back yard pointing hopefully skyward! (3) contains construction details for a 10 foot stressed parabolic array but this antenna would have to be modified for permanent service. Numerous microwave antennas available on the surplus market are also an excellent approach.

Satellite Receivers. Satellite receivers for 135-138 MHz service should be FM with a 30 kHz i-f bandpass (15 kHz selectivity). This will accommodate maximum signal deviation (9 kHz) plus worst case Doppler shift (4.5 kHz). Crystal controlled channel selection with crystals for 135.6 MHz (ATS), 137.5 MHz (primary NOAA), and 137.62 MHz (ESSA and backup NOAA) will be required. Sensitivity should be 0.1-0.2 microvolts for 20 dB of quieting. Older receivers will require a preamplifier to set a desirable front end noise figure. A preamp mounted at the antenna is highly desirable as it effectively overcomes line losses that would otherwise degrade the system noise figure.

Reference (23) describes a tube-type receiver and mast-mounted preamp. (21) describes a kit, modifications to a commercial monitor receiver, commercially available preamps, and tips on selecting a surplus receiver strip for weather satellite conversion. (6) describes a solid state receiver with PLL i-f that is very effective. Passable results can also be obtained by modification of a commercial FM tuner (9) but this is a very makeshift approach.

Display Systems. There are two principal options for display of APT or SR pictures – a facsimile (FAX) recorder for printing pictures directly on paper and a cathode ray tube (CRT) display on a television-like screen in which the image is photographed for analysis. Both types of display systems are capable of resolving all of the picture details in either mode and each has its own advantages and disadvantages. FAX systems are mechanical devices which make the picture display immune to factors such as stray magnetic fields that might distort a CRT display, yet they require some care to construct and operate and need some maintenance to keep them in top operating condition. Some forms of FAX will give instant pictures with features visible during picture readout, while even the most involved photographic systems require only a few steps to view the picture. Some FAX systems excel at resolving fine structure in bright clouds that might be obscured by trace blooming in a poorly designed CRT system. The mechanical nature of FAX,

Photo 4. Visible channel imagery from a NOAA 4 SR transmission as displayed on a photographic FAX system. In this case the images from the 48 line SR system were displayed at 96 rpm with alternate lines (the IR image) electronically blanked. Such FAX systems provide extremely high quality, especially in defining the structure of bright cloud features. This particular pass (7 August 1975) was directly over the Great Lakes, which are faintly visible in the center of the picture.

however, means that you are fixed to a single size format and changing picture modes involves complex mechanical and/or electrical changes or the construction of a recorder for each mode you wish to operate. CRT systems, in contrast, are relatively easy to construct and building them for multimode service is an easy task. Direct viewing of pictures is difficult, however, and photographs are most desirable. This is one handicap of the CRT option. Polaroid film provides instant pictures but at some expense if you read out large numbers. Roll film provides very inexpensive recording of the pictures but at some delay while the film is processed and printed. Such photos can, however, be printed at any size desired. Use of a CRT system involves less "fuss" than a FAX display, which is a factor that makes it desirable in situations where only occasional use is required. Properly designed systems of both types will be about equal in overall performance so the selection task is complicated. Active satellite stations often have both types in operation to fit the needs at hand.

The facsimile options are quite varied and a number of tradeoffs must be considered to determine which might be best for your use. The three major systems involve direct printing on film or paper using a modulated light source, printing on electrolytic paper, or printing on electrostatic paper. There is little doubt that photographic FAX systems offer the highest quality pictures – but at some inconvenience. They must be operated in the dark or near darkness in the case of systems that print on paper, and photographic processing is required. Anderson's pioneering work (2) describes a photographic FAX system for APT use which prints on film. McKnight's modifications of this system (7) result in a system that is somewhat more convenient in that printing is done directly on paper, thus reducing cost and time required. Ruperto (11) describes a direct printing photographic system derived from the work of W6KT, and Taggart (20) provides a complete construction article for a 48 line NOAA system along the same lines. Although both (11) and (20) are designed for 48 line SR display, either could be modified for APT with little difficulty. (21) provides full construction information and design data for a FAX system for 48 or 96 line SR display with modification notes for upgrading to future 120 line SR systems (Photo 4). With very slight modifications this recorder (120 line version) could also be used for APT service. Printing on electrolytic paper results in some loss of image quality but this is compensated for in some situations by the fact that the pictures can be printed out for immediate viewing in a lighted room. Winkler's SSTV FAX system (25) could be easily modified for SR or APT use – in fact, the SSTV version was a spin-off from his various satellite recorders. Photo 5 shows a sample of Winkler's APT readout on electrolytic paper – a picture from ESSA 8 in its better days! Electrostatic paper is perhaps the least satisfactory alternative, mostly due to the difficulty in getting a suitably good gray scale. Winkler's modification of a surplus Western Union Deskfax machine (26) is perhaps the quickest way to get some sort of FAX system going. While hardly the equal of these other systems in picture quality, Osborne's FAX recorder (10) certainly takes the prize for originality – it is built up around a windshield wiper motor and gear assembly!

Photo 5. Display of an APT picture from ESSA 8 passing over the west coast. This picture was displayed by Linsay Winkler using a homemade continuous readout FAX machine and Alden electrolytic paper. Although such systems do not have the ultimate in fine detail of a photographic FAX or CRT system, they are still excellent. The slight degradation in image quality is compensated for by the fact that the image can be read out in normal room lighting and is visible as it comes out of the machine. Similar continuous readout recorders are excellent for present and future SR systems as well.

CRT system options are quite varied and many approaches are possible depending upon equipment already on hand. Three alternatives are presently the most popular – display on an oscilloscope, display on conventional SSTV monitors, or construction of a monitor tailored for satellite picture display. The oscilloscope approach involves construction of a suitable "black box" that will provide Z axis video modulation to the scope and appropriate waveforms for horizontal and vertical deflection. Osborne's circuit (9) is probably the simplest of these and will give satisfactory results in the APT mode if a better receiver is used. Toben's circuit (22) is more complicated but will produce somewhat more reliable results. Kennedy's system (6) is the most elegant of the group and will provide excellent results in both APT and SR service.

The popularity of SSTV has led a number of people to experiment with display of satellite pictures on slow scan monitors. (13) is a very simple APT adapter that can be used with a number of monitor circuits and suitable modifications for adding SR display are included in (14). Additional circuit ideas are incorporated in (17) that permit use of the adapter with Robot monitors or even TV sets. Owners of Robot SSTV equipment should consider contacting Robert Schloeman WA7MOV, who has designed an excellent adapter circuit specifically tailored for use with the Robot SSTV monitor.

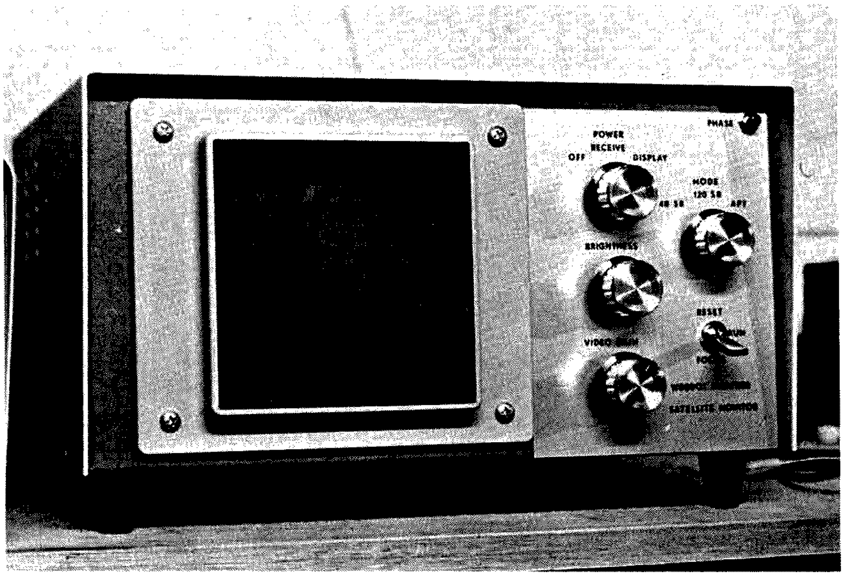

Photo 6. A solid state multimode satellite monitor built by the author. This circuit is featured in the Weather Satellite Handbook (21) and has switch-selected options for display of 48 line SR, future 120 line SR, and APT picture modes. Such monitors are compact and are quite easy to operate, making them a highly desirable project for stations seriously interested in weather. Using all new components and high class packaging, such a monitor still costs less than $300. Less elegant packaging and a search for junk box components can reduce costs to a fraction of this even in such a comparatively advanced project.

The construction of a complete display monitor is perhaps the most reasonable approach for individuals lacking extra oscilloscopes or SSTV monitors. Vermillion's report (23) describes a monitor of sorts built around a commercially available oscilloscope module. Spillane (12) described an APT monitor using tube circuits that would still be useful with some modifications of the sync detection circuits. The advanced version of Osborne's circuit (9) is another choice for APT display. (21) describes a complete multimode solid state satellite monitor complete with printed circuit artwork and component layouts. Photo 6 shows a version of this monitor which is also described in (21). The latter reference includes data on the simple addition of 120 line SR capability which is incorporated in the unit shown (48 line SR, 120 line SR, and APT capability). Such a monitor certainly represents the ultimate in a compact display system.

Satellite Tracking. Although tracking of polar orbiting spacecraft appears to be an imposing task, it is not at all difficult to accomplish. (24) is interesting reading regarding satellite orbits in general and (15) outlines all the essential features involved in satellite tracking. (21) contains a full chapter on the subject which in addition to the tracking of polar orbiting satellites also includes aiming data for geostationary satellites, alternate sources of tracking data, and a simplified model for long term orbital predictions.

Accessories. These components include desirable station features that are not absolutely necessary but do improve operating convenience. (16) describes a digital orbital timer that eliminates the need to acquire daily prediction data or interpolate from a clock when tracking and (18) describes the use of such a timer to completely automate station operations, including turning on the recorder, tracking, and station shutdown at the end of a pass. (17) includes some useful accessories such as an active 2400 Hz filter and a crystal controlled 2400 Hz reference source, either of which would be a useful addition to many of the systems covered in these references. Brush (4) describes a novel circuit for contrast enhancement in the SR IR channel display and (23) includes a more complicated circuit to accomplish much the same task for FAX display.

This about covers most of the technical features. A very interesting summary of different weather satellite products is contained in a report by Hoppe (5) that not only describes the pictures from various satellite systems but also shows the different ways in which these are computer processed and mosaicked for greater utility. If you get a system in operation you might wish to learn a little more about how the cloud systems you see relate to surface weather. A wealth of information on this subject is contained in Anderson's paper (1) which, with a little study, will enable you to derive really meaningful data from your cloud pictures.

Now there are probably lots of readers of this article who might never consider setting up a satellite station. You have read this article out of curiosity and the desire to simply learn a little bit about another facet of this far-flung hobby of ours. This is one of the things that makes it interesting to receive your magazine every month. But even if you are not interested in weather satellites, let me outline a challenge that may appeal to some of you. I have mentioned previously the difficulties involved in putting together a suitable S band converter for use with the SMS/GOES satellite series. The commercial modules (8) are far too expensive for most satellite buffs and Roy Cawthon's success was due in large part to his willingness to invest a fair amount of money and a huge block of time in getting his system going. It is not one that could be easily duplicated by stations now receiving ATS WEFAX who would like to get in on the action up on S band. Several amateurs are actively working on the design and construction of suitable S band converters in the hopes of pushing down price and complexity to the point that others could think seriously about adding S band capability to their operations. It is too early to say if these efforts will be successful but it is a virtual certainty that a lot of you out there are seriously interested in UHF and microwave experimentation. A successful S band converter would be a boon to satellite stations throughout the world and there is no doubt that should any of you develop such a system, you could certainly put together a description of the circuit that would instantly be accepted by a magazine like *73*. The specifications run something like this:

Input Frequency – 1691 MHz
Output Frequency – 137.5 MHz
Front end noise figure – 2.5-4.5 dB
Front end gain – 20 dB min.
Mixer noise figure – 9.5 dB max (assuming 1.5-2 dB first i-f noise figure)

NASA's solution is a $900 preamp, a $200 mixer, and a $900 LO chain for a total converter cost of $2000. With today's technology it would seem that amateurs could do the same job for $200 – maybe a little more, perhaps somewhat less. Any UHF or microwave buffs out there who would like to give it a try? I would be happy to correspond with anyone who would. Any approach is valid although perhaps microstriplines are best from the point of view of easy duplication. Maybe you like to design but hate to build, in which case microstripline design data around specific rf transistors would be most welcome – needless to say full credit would be given for any successful design input. Perhaps you have access to suitable S band test equipment and would be willing to help set up gear that others might construct – if so I would certainly like to hear from you. An easily

duplicated S band converter would make you famous in weather satellite circles even if you never watch a single picture – see how easy it is to get involved? Hundreds of APT stations throughout the world will be out of business in terms of WEFAX if such a converter is not forthcoming before the ATS satellites expire. This one area is certainly a challenge to anyone with the expertise to once again show the "professionals" what amateur radio can accomplish. The more people who are working on this particular task the more certain will be an eventual solution!

Experimenting with weather satellites is certainly one of the more fascinating peripheral areas in which amateurs can participate. One of the simpler systems represents an ideal short-term project to discover if you might be interested, but even the most sophisticated systems, equal to commercial display units costing over $10,000, need not be expensive. The multimode monitor shown in Photo 6 is capable of displaying pictures from present and future APT and SR systems and yet even with the comparatively "deluxe" packaging employed it can be built for less than $300 – less than a commercial SSTV monitor. For less than what some amateurs are willing to spend on one of the newer FM transceivers it is possible to construct a complete satellite station that will operate when you aren't even home. Stations with fewer refinements have been constructed by students as science fair projects for a small fraction of this cost. Why not look through some of these references and give it a try? ■

Photo 7. One drawback in improperly operated CRT display systems is that trace "blooming" often obscures fine features in very bright clouds. This photo of a NOAA pass over the central U.S. on a very cloudy winter day shows that properly operated CRT systems need not have this problem. This particular picture was displayed on the 5" CRT monitor described in reference (19).

HAM HELP

The first thing I would like to say is that I think you have a very fine magazine. You sure did a good job of getting my interest back into ham radio. I picked up your November issue out of curiosity, as I was brousing around a magazine counter. I had a Novice license back in 1967 and 1968 when I was in high school. But after that I sort of lost interest. As a result of that issue, I also picked up your January issue, which was as good as the other, if not better. Your influence caused me to purchase your 14 wpm tape to help get the old code speed up to at least a tolerable level by the FCC.

Now for my problem. I would appreciate it if any of the readers in the Warminster, Pa. area have any information about ham clubs in this area. I would like to get involved with one, plus at the same time it will help me to get back on my feet again.

Scan Your HR212

Wanting some type of scanner for my Regency HR212, I got out all my ham magazines and came upon the scanner described by K2LZG in the February 1973 issue of *Ham Radio.* I had never built anything using ICs, so I said to myself you might as well get started now as never. After many nights of burning the midnight oil, I finally came up with the right hookup for the HR212.

The channel selector in the HR212 applies a ground to the appropriate rf choke (L501 through L512) which places a forward bias on the diode. This action provides an rf path for the crystal to turn on.

I use a +2 volt signal to stop scan and a zero volt signal to enable scan. You can take the squelch voltage off the white jumper wire which is located near Q105 and C137 located on the i-f-audio board. You can pick up the 12 volts anywhere after the on-off switch; I took mine off the red wire on the on-off switch. To connect the six oscillators to the scanner I connected six wires, one to each rf choke (L501 through L506). Be sure to connect to the side of the choke going to the channel switch. I built my unit in a small plastic case obtained at the local Radio Shack. I used a small male jack mounted on the back of the box and brought the nine wires out the HR212 to the female plug. Also, I mounted six SPST toggle switches in series with the oscillators to the scanner, so I can switch any channel out I don't want to monitor. I mounted a SPST switch in series with the 12 volts to the scanner to switch off the scanner when I want to transmit. I use a MAN-1 7 segment readout for the channel indicator.

To use as a scanner just turn the channel switch to any unused channel and flip on the 12 volts, and scan away to your heart's content. ■

I/O EDITORIAL

WANT TO MAKE A BUNDLE?

Not to be a name dropper, but sure as God made Yellow Transparent apples (to me the finest apples in the world) someone may make a fortune by coming up with a small computer system for small business and home use . . . if he plays his cards right. Best of all, nothing further has to be invented to make this a reality . . . some of the pieces have only to be put together.

Since a small black and white television set retails for around $85, a keyboard for $30, a microcomputer chip for $20, a cassette recorder for $20, how much could a small computer system cost embodying these elements? Oh, you'd need a display generator for the TV, an interface for the cassette, and some working memory. I'll bet someone could put such a contraption on the market for under $1000 in six months . . . and the price would be down to half that in six more . . . and eventually down to maybe $250 . . . or $125. The prices go down a lot when chips come available to handle each function . . . and eventually the whole works.

They're already starting to put RAM memory on CPU chips . . . and I/O interfaces too. Add a small built-in ROM operating system and a TV display generator . . . and the price plummets for a complete small computer system.

Do you want to wait for someone else to get into the business or start working on it yourself? Here's a way for someone to invest some time and money in a project which could be worth millions in a couple of years. MITS had about 15 people when they entered the uP business . . . now look at 'em!

HAM COMPUTING

Most of us can think of a lot of good things we might do if we had a computer . . . like keep track of stations contacted along with some details about them . . . maintaining an index to ham magazine articles that we might want to look up . . . determining Oscar intercept times and bearings . . . running all the functions of a repeater . . . playing any of the hundred or so popular computer games . . . getting into computer art forms with a color television set . . . experimenting with computer music . . . keeping track of repeater channels and locations . . . Morse code conversion . . . RTTY operation . . . things like that.

But the next question is a tough one . . . what hardware will it take to get involved in my interest . . . and, even more difficult, what programs . . . and where can I either get the programs or get the training so I can develop my own programs?

Frankly, we could use a lot of input on both hard and software. Let's see some articles on this . . . showing configurations of available gear which will do ham and hobby jobs.

If we look at the Sphere equipment we see that for most ham applications we will need their "200" system, their "B" package and BASIC on cassette. This comes to $860 for the "200," $205 for the extra 4K RAM memory and character generator ROM of package "B" and $100 for BASIC on a cassette . . . total $1165 for the hardware. Now, if you buy the BASIC textbook by Albrecht ($4), you will be ready to go with almost any program you want, doing your own programming. The DEC 101 Games in BASIC ($7) will launch you into the game biz. You will need a television set for the display.

The Sphere system will give you the computer, a character generator so you can read out the input and output of the system on a television set, a keyboard for inputting, BASIC programming language which takes about 5K of RAM memory, leaving about 3K for your use, and an I/O for a cassette recorder for use in entering programs, storing programs for later use, and storing data in long-term memory. That's a fairly complete small system.

If you want to go the MITS route you'll need an Altair 680 ($420), 12K of RAM memory ($825), an I/O port to interface the 680 with a video display terminal ($144), BASIC language on cassette ($75), cassette interface I/O port ($144), plus some sort of video generator and keyboard unit such as the Southwest Tech kit which runs about $282 (and then you have to build it . . . which is fun). The cost of this system would appear to come to around $1890. If you want to go the Altair 8800 route . . . and Ed Roberts points out in the Altair Computernotes publication that the 8080 chip is substantially better in his estimation than the 6800 chip . . . this would increase the cost even more.

The Altair 8800 computer is $621, expander boards are $93, a cooling fan is $20, three 4K RAM boards are $825, the cassette I/O is $174, the television typewriter I/O is $144 and BASIC language on cassette is $75, plus the $282 for the TVT kit comes to $2234.

To do any work involving data you want to keep on file you will need a couple more cassette control systems so you can use one cassette for your data base, a second for any update to the data base, and a third for the updated data base. This means two more I/O interfaces and control systems . . . it also means a lot of programming using BASIC. If you want to keep a file of every station you've contacted and be able to quickly get the data on someone, this is the system you'll probably want.

The same system would work fine for keeping track of magazine articles you might want to reference, recipes for the wife, addresses for a club, a file on music in your record collection, a list of repeaters, etc.

These systems will be a little slow in locating data in memory since they will have to scan your cassette tape for the data file wanted. It won't be long before we have relatively inexpensive tape systems which can be searched much faster . . . and relatively low cost floppy disk memory systems are on the way. Disks don't hold much more than cassettes, but they search very rapidly.

There are a lot more small computer systems coming along, but I haven't got much data on them as yet. It is almost impossible to understand some of the advertising literature in this field and even talking with the manufacturers can be frustrating, for some of them are so busy designing and turning out parts of their systems that they haven't given much thought to what it will be used for . . . or what problems the user may run into.

I would like to state that *73* is most anxious to hear from any ham computer hobbyists who have managed to put small systems together and get them to actually do something. Please let us know what you are using and how you programmed it. I would also be delighted to hear from *any* manufacturer who can state just what hardware and software is needed . . . and how much it will cost . . . to set up some hobby systems such as outlined above.

For instance, any of the small systems being marketed are quite capable of calculating the Oscar acquisition times, but where can you get the program for the calculation? Unless it is in either machine language for your particular chip or in BASIC, you won't be able to do much. And it has to be in a BASIC that is compatible with the BASIC you've got for your computer, just to make matters a little more complicated, for there are BASICS and then there are BASICS, from Mini-BASIC on up through Extended BASIC. Obviously we all need to know a lot more about this situation . . . and get some counsel on where to get the programs we need for Oscar, moonbounce times, etc.

Now is the day of the true pioneer as far as microcomputers are concerned . . . like sideband in the mid-50s . . . like FM in 1969 . . . and RTTY in the late 40s. We are a long way from the appliance operator phase of uP systems and these are the days which separate the men from the boys. Let me emphasize again that having fun with computers does not take super brains . . . it does not take a whole lot of money . . . it does not take education . . . all it takes is enthusiasm and persistence. And, if you are young in spirit, there is a very good chance that you can parlay your knowledge into a very comfortable living.

THE MAGIC OF FRESH ORANGE JUICE

The other morning, as I was squeezing oranges, I had a depressing thought. I remembered a bit on a recent Today show lauding the wonders of Florida. It was a film about the citrus industry there and they mentioned that two thirds of the Florida oranges are now processed into frozen concentrate. How many years since you have had fresh orange juice for breakfast?

Once you get into fresh orange juice you have a tough time gagging down the frozen stuff . . . or the "fresh" juice in cartons. You have to totally forget what orange juice tastes like to accept frozen. An electric juicer runs around $10 to $12.50 (Unity or Sears) and you can crank out a glass in about a minute . . . you don't thaw out a can of frozen much quicker.

Just as we have all come to accept the frozen juice alternative to do-it-yourself juice, with a loss of substance, most of us hams have come to accept our ham gear as either ready-built or in kits (paint by the numbers?). I have a strong feeling that the computer revolution in amateur radio will bring back a lot of the home squeezed flavor to our hobby . . . for, even if you work from an assembled or kit computer, you are still only about 25% of the way toward your goal. This is one field where the hardware is only the start and merely opens the gates for self-expression and creative fun via the programming you will be doing.

I hope that the manufacturers of computers won't be angry at me for letting the cat out of the bag, but the fact is that getting your equipment working is only a small part of the fun and challenge. Oh, in time a lot of the work will be done for you and will be available on tape or something . . . perhaps ROMs. At least, programs will be available for ordinary uses of the equipment . . . you will still be on

Computer Languages-- Simplified

Anyone who wants to use a computer has to have a way to communicate with it. This article is a simple introduction to some of the languages which are used for that purpose. It is intended for rank beginners, so all of the programmers, software freaks and computer hot dogs in the audience might as well stop here. For anyone else, I'm going to try to keep everything in English (which is not a computer language, unfortunately) and avoid as much computerese as possible. So here goes.

One might start by asking, "Why have computer languages at all?" Back in the dark ages 25 or 30 years ago they didn't – the machines were wired up to do a certain thing and that's what they did. But, somewhere along the road, some bright fellow realized that it would be much more efficient if you could feed the machine a fairly long set of instructions and let it follow them. This also made for much greater flexibility, since you could give the machine different sets of instructions. These instructions are what a computer language communicates, and this article will go over some of the more common ones, to wit: Assembler, BASIC, FORTRAN, PL/1, COBOL and a little bit about some of the more specialized ones. But first let's look a little bit more at the nature of the beast we're dealing with.

It is helpful to think of a computer as a glorified electronic calculator. In fact, some of the more modern calculators really are computers. But let's look at the average four function calculator. It has a display, which is called an output device in computerese, and it has a keyboard, which is an input device. To do anything with it, you have to enter the numbers through the keyboard and then enter what you want done with them, be it to add them or whatever.

> Machine language is the closest we can get to what the machine actually speaks.

But suppose you want to do a mortgage calculation – say, figure out what your interest payments and principal payments are going to be each month for the life of the 20 year mortgage. This means that you're going to have to do a very repetitive calculation 240 times. It is to avoid this sort of hassle that real computers (and some fancy calculators) have stored program capacity – a stored program being nothing but a set of instructions inside the machine which get done without your standing there pushing all of the buttons each time. But now we have to get this set of instructions inside the machine, and that is where programming languages come in. We need a way to communicate the instructions to the machine.

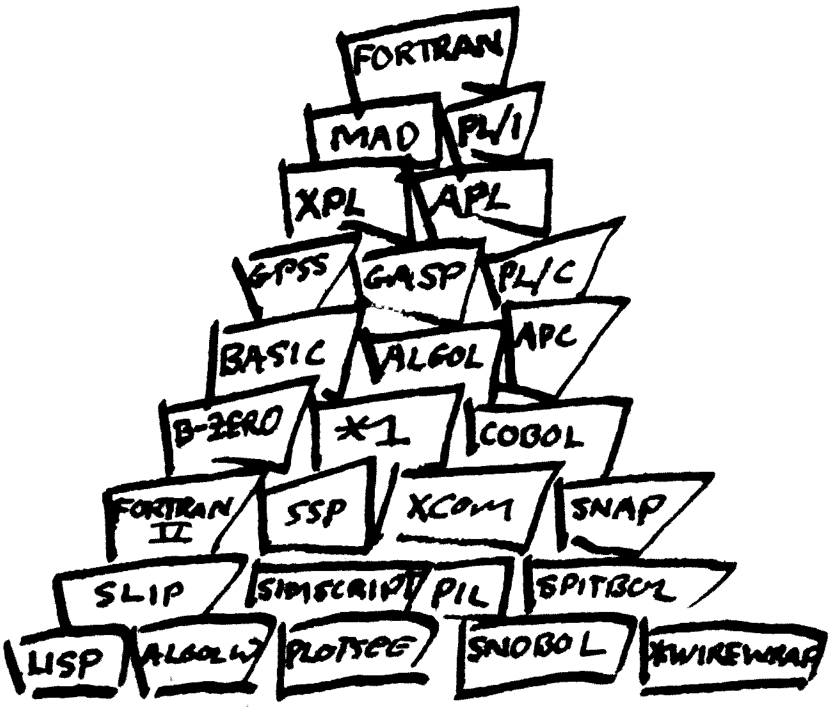
In the case of a calculator, this isn't much of a problem. The "Instruction Set" (list of all of the instructions which the machine is able to follow) is hard-wired in. If you want it to add, you push +. This is obviously not too good an idea for a large computer, since the number of buttons gets pretty large. Besides, you tend to run out of symbols, which makes everything even more confusing. So we need some sort of language. The simplest one is called "machine language" and is the closest we can get to what the machine actually speaks. However, as any of you who have been following the articles in *73* about gates and such know, computers and other digital machines run on high and low levels of voltage. Since this is rather hard to see, we usually represent it with ones and zeros, or on and off lights. The whole thing is like trying to communicate using RTTY but doing it by ear instead of with a TTY machine, which is to say that it's a royal pain. Anyone who's into interpreting things like 01001101 01100001 and so forth can really get off on it, but for most of us there's gotta be a better way. Fortunately there is. Incidentally, if you ever get a microcomputer, those switches and lights on the front panel are used to communicate with the thing in machine language.

The next sort of language developed, and the one which is most widely available for microprocessors these days, is the assembler. Each type of computer has its own version; what it is, in short, is machine level logic – but using symbols and normal numbers rather than ones and zilches. Assembler is related to what you do with a calculator – in fact, any of you who own or use HP calculators have been using a version of assembler language usually known as Reverse Polish Notation. With an assembler language, you specify what number you want, where you want it put and what you want done with it; for example (to use HP assembler): "12, ENTER [*which puts it in the region where the arithmetic is done*], 2, x" multiplies 12 times 2 and comes up with

24. All assembler languages work this way, although many of them have dozens of commands and hundreds of locations where things can be put or obtained. This sort of computer language has a lot of advantages. It's very efficient not only where memory is concerned, but also with regard to execution time. This means that it's cheap to use. The assembler (the program which translates it into machine language) doesn't take up much memory either, which means it can be used in a microprocessor which doesn't have much memory (and memory costs like the devil, even these days). Using assembler, you can also anticipate situations where the machine might do something unexpected, since you're on the machine's logical level. Of course, it's got its problems too. It's hard to learn, not easy to use well, hard to debug (find errors) and is "machine dependent," which means that each machine has its own. To sum it up, a lot of people don't like to have to write: "12, enter, 2, x." They'd rather write "A=12 x 2." This is what "high level" languages let you do, along with all sorts of other convenient things. For this reason, almost all programming these days is done with one of the various high level languages, and the rest of this article will be about some of the more common of them.

First of all, a high level language is a computer language that is based on some combination of English and algebra. So, to write two plus two you would usually write "2+2." To tell the machine to print, you write PRINT, WRITE or something of that nature. The one thing to watch out for is that, although there are many different ways of writing one thing in English (and to a certain extent in algebra), a high level computer language has a very narrowly defined structure and vocabulary. This means that the computer equivalent of "I ain't got none" will be rejected. In other words, you have to be very careful when writing any sort of program for a computer, since errors (the computerese term is glitches) get caught faster than they would be by an old-fashioned high school English teacher.

Continuing the comparison with human languages, there are lots of different ones for computers, too. At first each company developed its own; now many of them are standard and thus can be used on any machine with few, if any, changes – unlike assembler languages. We still have a lot of computer languages, though. For example, the last time I checked the documentation, there were something like 35 different high level languages available for use with the University of Michigan computer system. The reason for having so many is that each language is designed to do some particular thing well (in jargon, they are problem based rather than machine based). This means that one language is good for mathematics (also called number-crunching), one is good for electronic circuit design, another for library use, and so forth. There are also a couple of general purpose languages – which happen to be the most popular for obvious reasons.



It would be a pain to have to spend a few weeks mastering a new computer language every time you wanted to do something different with a computer – not to mention that you have to buy (or write) a special translating program (called a compiler) for each one – and that can get very expensive (much more than the cost of the computer itself). So let's look at some useful, fairly general purpose languages.

BASIC, which stands for "Beginners' All-purpose Symbolic Instruction Code," was developed at Dartmouth College a number of years back. It was designed for people who knew nothing about computers but who wanted to use them. Few dyed-in-the-wool programmers care much for it, but most non-programmers love it. It's based on algebra, and the non-algebra parts of it are in plain English. For example, to enter two numbers into the machine, multiply them, divide one by the other and print the results, you would write:

```
1 IN A, B
2 LET C = A * B
3 LET D = A / B
4 PRINT C, D
```

(* is the standard symbol for "times" on a computer)

This language has quite a few advantages. It's easy to learn, easy to use, and there are lots of books around which help people learn it. Equally important, there are lots of programs already written and published in it (these are called canned programs), and quite a few computers can use it. In particular, Altair has two (going on three) versions out at the moment, and other microcomputer manufacturers are making noises about supplying it – or so I read. The compiler (remember, that's the program which translates the things you write into the machine's language) doesn't take up too much memory

either, which means that BASIC is suitable for small computer systems where memory is limited. A final advantage is that BASIC is fairly flexible – especially the advanced systems. You can do many if not most of the same things with it as you could do with FORTRAN or PL/1, although the programming effort might be greater.

It does have some disadvantages, though. BASIC has no mnemonic variables. This means that you have to remember that A stands for current, E for voltage and so on. In a more advanced language you could write AMPS, EMF, etc. This isn't so bad if you're working with standardized symbols, but gets to be a disadvantage when you try to remember which was Accounts Payable and which was Accounts Receivable. Also, BASIC is somewhat limited as to what you can do with Input/Output. This only makes a difference if you are working with a big system that gives you lots of choices – it isn't of too much concern for a home computer system or a small business one. Finally, BASIC is structured somewhat along the same lines as FORTRAN, which is the oldest computer language still in use. This means that it does a lot of things in harder more roundabout ways than some of the newer languages, like PL/1. For example, its "either-or" choice is rather cumbersome to write. It's still a great language to play around with, though.

FORTRAN is probably the best known of the various computer languages, partly because it's one of the oldest. The name stands for FORmula TRANslation, and it was developed by IBM back in the early 1950s. It and the B-Zero language developed by Univac were the first high level languages used. No one uses B-Zero today (few have even heard of it), but FORTRAN is probably the most widely used computer language in the United States. Of course, the FORTRAN we use now isn't the same as the FORTRAN introduced back in 1957 – just as the English we speak now isn't the same language as the people in England spoke back in 1066. There have been three official versions of FORTRAN: FORTRAN (the original), FORTRAN II and FORTRAN IV. Number three got lost in the middle somewhere. Most computers these days use FORTRAN IV, although there are some minicomputers around that still use FORTRAN II; some of these compilers might be adaptable to microcomputer use. Anyway, as you might guess from the name of the beast, FORTRAN is basically a scientific computer language; it was developed to make it easier to solve mathematical-type problems for science and engineering. Over the years the language has expanded to the point where it is usable as a general purpose language, so it can do a lot more than simply crunch numbers. Moreover, since it's such a popular language, there are who-knows-how-many programs written (and sometimes published) in it, which makes it much easier to solve a given problem (since you can frequently just type in a canned program). The same structural problems encountered in BASIC are part of FORTRAN, but these have already been covered. Perhaps more important for anyone who wanted to use FORTRAN on a microcomputer, the compiler (remember? the program which translates it into machine language) takes up much more memory than a BASIC compiler, though much less than one for most other high level languages. One keeps hearing hints that one of these days someone may develop a version which is usable on a microcomputer, but I haven't seen any announcements yet.

While FORTRAN was developed for scientific use, COBOL was developed for business use. It's the language used by the U.S. government for a lot of their stuff, so it's got a pretty wide circulation. Needless to say, many businesses use it, too. From the little work I've done with it myself, it seems that you spend most of your time defining what your printout is going to look like and what the information which you feed into the thing is going to look like (the jargon for this is format definition). It also takes lots more memory than one would probably want to pay for in a microcomputer – unless he wanted to do subcontracting for the government.

> BASIC ... was designed for people who know nothing about computers, but who want to use them.

Up until the early 1960s, most computers were either scientific- or business-oriented, and a machine which was designed for one didn't usually work too well for the other. Then IBM started making their general purpose machines, and most other people followed suit. At about the same time, people started to worry about a general purpose computer language. A number were developed, of which my favorite (just for the name) is MAD (Michigan Algorithmic Decoder) which was brought to us by the folks at the University of Michigan Computing Center. Then IBM got into the act, and, lo and behold, out popped PL/1 (Programming Language One). The best description that I can think of is that it was designed to out-fortran FORTRAN and to out-cobol COBOL all at the same time. It does a pretty good job of it, too. I'm always amazed at all of the nice things you can do with PL/1; to use the computerese phrase, it has more bells and whistles (extra options) than you can shake a stick at. Unfortunately, it also uses more memory than you can shake a stick at, which makes it too expensive for microcomputer use (or even timesharing use if you have to watch your costs). But never fear, one of these days we may be seeing a scaled down version of PL/1 (called PL/M) which keeps a lot of the nice features without taking up more memory than most of us mere taxpayers can afford. To give an example of the sort of nice thing the language can do (among others), it lets you write a simple either/or statement (if this is true, do one thing; otherwise do this other thing), whereas to do that in most other languages you have to play hopscotch with the line numbers. In short, PL/1 is a great language, and if a cheap compiler ever comes out, I hope I own the microcomputer it's written for!

Another new language, again by IBM, is APL. I will confess here and now that I've never used it, so what I say is taken from what people who have used it have told me. This is a very powerful language; it can do in one line what most other languages require five or more to do. It

is not yet widely used; unless I'm mistaken (which is quite possible) IBM is the only company which makes compilers for it. It *is*, however, designed for the sort of sit-down-at-your-computer use that most hobby users probably have in mind. And good news! It's available for a microcomputer. The bad news is that said machine is the IBM 5100 and it runs about 10k – and those are kilobucks, not kilobytes. Anyway, the scuttlebutt has it that APL is one of the languages to watch, so keep your eyes peeled.

I mentioned a while back that, in addition to the general purpose languages I've discussed so far, there are quite a few special purpose ones. For a hobby user (or would-be user) these aren't too important, but just to be more or less complete I'll mention a few which are good with which to impress people (besides being good to know about if you tend to be around computer hot dogs who like to talk about such things). There is RPG, which is a Report Generating language, and therefore much used for business and that sort of computing. Then there are several languages used to write simulations. (A simulation is like a computer game except people take it seriously. Come to think of it, I know a couple of people who take the Star Trek game seriously, but we'll ignore that.) These languages are things like GASP, GPSS and so forth. There are a fair number of languages used for crunching words instead of numbers – SNOBOL, SPITBOL and so forth. Finally, there is at least one language used to design electronic circuits – unfortunately all my electrical engineering friends seem to be able to tell me is that it exists and Professor Zilch mentioned it.

FORTRAN ... does things in harder more roundabout ways than some of the newer languages, like PL/1.

As a brief review, one needs some sort of language to give a computer instructions. You can operate on the machine's level (called machine language) and feed it ones and zeros. Or, you can stay on the machine's logical level but use decimal numbers and abbreviated commands. This is called an assembler language, and requires a separate program for translation into machine language. Finally, you can use a combination of human logic and normal words and symbols, which is called a high level language. This requires a program to translate it into machine language again, and such a program is called a compiler. The principal advantages of high level languages are that they are easy to learn, easy to use, and are the same for any machine. They are not nearly so efficient as assembler language from the computer's point of view, but they are much more efficient from our point of view – and that's usually what counts. ■

LETTERS

from page 8

you KNOW you have the signal right on the nose.

I'm playing around with a phase shift TTY converter which seems to promise great things. I wonder if you would have any interest? *(Of course . . . Wayne.)*

New subject: mini-computers (micro if the shoe fits). I think one of the great problems facing the would-be computer hobbyists is that the manufacturers, in their ads and more amazingly in their literature, seem to be quite reluctant about two things: one, a simple block diagram showing the necessary basic cards/modules and how they plug together; and two, a simple format of how a program on their machine looks and what the owner has to do to make the thing work. Hiding these things, either on purpose or by oversight, may prevent many would-be's from getting into the act.

I have been fooling around with systems analysis and programing computers for quite a few moons now, particularly as they relate to communications services and facilities, and it seems to me that the manufacturers are missing a good selling tool by not explaining, in English, what's going to happen when he does this and that. None of the literature that I have received (and I've got them all) from any of the manufacturers has given me the slightest clue as to what to expect or indeed what to buy to do such-and-such.

UPKEEPING

I think you've got the best magazine in ham radio — and hobby electronics in general too, since *EI* went out. Keep up the good work.

Eric Williams
Scotts Valley CA

FAR OUT

I almost had a heart attack today (and I'm only 19). I received my March issue of *73!* None of the other ham magazines has gotten here that quick . . . FAR OUT!!! Keep up the interesting articles. I hope sometime in the future I see articles on building ATV stations and more on microprocessors (I'm getting interested and can use some info).

Bob Billson WA2TXY/AA2TXY
Westfield NJ

SNOBBISH?

I guess you talked me into becoming an amateur. I've been reading *73* for a couple of months now and I finally decided to take the steps necessary to acquire my ticket. Enclosed is $13.95 for a full set of the code tapes. As an amateur, you have a refreshing outlook on the CBer and his or her potential as an amateur recruit. This, in addition to the fine articles in the magazine, is the reason why you got my twenty bucks for a 3 year subscription to *73*.

I have been servicing citizens band and amateur gear for a couple of years now, and the snobbish outlook of amateurs has kept me out of amateur radio until now. There must be more amateurs in this country with your outlook on the CBer, and I have decided to take the time to find some of them.

Thanks for the fine magazine.

Michael L. Aber
Vallejo CA

ILL WINDS

I recently subscribed to your magazine as a result of again becoming interested in ham radio. Although I have been active in years past (formerly W8LST, KR6OX and 5A2TY), I have not been active since my last license expired in 1963.

I just received the March issue and as I was scanning through it, the article, "Inherit the Wind," came to my attention.

The first time I read the author's instructions for building the anemometer, particularly his logic used in calculating the 2.80" radius for locating the 1/8" hole in the disk assembly, I couldn't believe that I was interpreting his logic correctly. After reading it a second time, I concluded that he either goofed in his line of reasoning or he is trying to test for reader response.

He indicates that the 1/8" hole should be drilled in the disk at a distance of 2.8" from the center. The only purpose for the hole, as I see it, is to allow a pulse of light to reach the photoelectric device once per revolution of the disk, and this can be done whether the hole is 2.8" or 2.8 feet (or 100 feet) from the center, as long as the photoelectric device is aligned at the same distance to match the hole when it comes around.

In order to receive one pulse of light per second per mph of wind velocity, it will be necessary to space the cups on the anemometer cup assembly properly from the center of rotation so that the circumference corresponds to the distance that the wind molecules travel in one second at one mph (assuming 100 percent efficiency), and I will accept his calculation of 2.80" for this radius.

Although I haven't built this anemometer, it seems that 2.80" might be a little short to obtain good efficiency. I would suggest therefore, that the radius figure be doubled or tripled to overcome this possible drawback.

Doubling or tripling the radius would of course reduce the revolutions per second by 1/2 or 1/3 respectively. This could be offset by drilling 2 holes or 3 holes, respectively, equally spaced around the disk at whatever radius the builder decided was most desirable. This would still allow the photoelectric device to see one pulse per second per mph of wind velocity.

FOREVER GRATEFUL

I am a tolerant ham wife. I don't make plans for Sundays when there are hamfests. I don't complain when I am "widowed" on contest weekends. I have accompanied my husband to several conventions when nobody else could go. I read *73* (at least the "Letters" section — I understand that!!). I even put up with being called an XYL when I'm not really sure whether the *X* means I'm no longer young or no longer a lady! But now I have a request of all of the hams, and as it probably is not unique with me, I feel it bears voicing.

OM, when you come to eyeball with my husband or to work on equipment, please leave your toddlers at home. I will carry coffee or beer to the shack. I will hold wires while you solder. But please, *please* don't ask me to babysit. If I weren't at home, you would be responsible for your child's welfare. You know how impervious you are to your surroundings when you get involved in a project. Would you want your child loose in your shack at such a time? I know your wife deserves a break, but not at my expense. So I promise you, I won't let my husband bring our child to your house if you don't bring yours to my house. Give your wife her break some other time, and I will be forever grateful.

The X-babysitter
(Name and address submitted)

ADS TOO, DREAMS (?)

Mahalo, keep up the good work. I look for the *73* for days before it arrives, and it disturbs my sleeping habits until I read it cover to cover (ads too, dreams).

Everett W. Curry, Jr.
K6VGL/KH6
Honolulu HI

THE METRIC SCOOP

Why don't you scoop *QST* by being the first to go the metric paper size? Eventually, why not now?

Ken Lewis WA4QHZ
Albany GA

Excellent idea! Behold . . . 73 *Magazine, the first of the 21 x 27.5 cm magazines! — Wayne.*

EERIE

Thank you for the special surplus section in your March issue. To a "surplus hound" like me it was interesting reading. Keep it up!

J. K. Bach, who wrote the article titled, "Adventure," might be interested in some information concerning the calculator he bought. He has a *Lloyds Accumath*® *60*. It sold for about $60 to $85 new and was discontinued two years ago. The unit was built by North American Rockwell (this is where I came in contact with it) and probably assembled in Mexico. Readers who have this calculator *might* be able to obtain replacement parts by writing Lloyds' service department located in Compton, California. I must say it is an eerie feeling to read about a product you have worked with since its design stages described by someone with pinpoint accuracy who doesn't know what he has!!!

WORTH A TRY

The following is a little tip that I've "re-invented" and which might be of some interest to your readers. At first I was somewhat puzzled by the occasional "zeroing" of my digital LED wristwatch for no apparent reason. I thought about intermittent internal connections (ugh), strong rf fields, etc., but then finally narrowed it down to simply a static charge build-up on the red plastic faceplate of the watch itself. Going back through my memory bank, I remembered the sure-fire cure for static build-up on plastic meter faces used by hams all over for the last dozen or so years and my problem was solved. In case you've forgotten, the cure involves merely placing a couple of drops of liquid detergent (Ivory in my case) on the faceplate, spreading it around with a finger-tip, letting it stand for a minute or so, and finally wiping the bulk of the detergent off. A thin film of detergent seems to remain behind to protect against further build-up for some time, but it is a good idea to re-coat the faceplate every couple of weeks, especially during the cold, dry winter months. No one can guarantee that this pro-

cedure will work for all digital watches, but it certainly is worth a try before packing it off to the manufacturer for repair.

David F. Miller K9POX

CREDIT LIMARC

At a hobby exposition on Sunday afternoon, January 25th, sponsored by the Plainedge Public Library in Massapequa, N.Y., members of the LIMARC ATV technical group gave an on-the-air demonstration of amateur television two-way transmission between W2WLS/2 and W2NIP. Amateur color TV transmissions were also demonstrated as was a complete solid state ATV transmitter developed by W2TRP. Other participating ATVers were WA2APJ, W2ZUC, WA2FHF and W2KPQ.

Also shown were exhibits of slow scan TV, repeater operation, and an exhibit of a precision radio controlled boat built by WB2AQM.

K2QPF, emergency coordinator for the town of Oyster Bay, demonstrated traffic handling during the simulated emergency test on this date. Other groups who joined in with exhibits were the Wantagh Radio Club, the Farmingdale Radio Club and the Long Island DX Association represented by WA2BVU and W2AWK. Amateur radio in the scouting movement was ably handled by WB2YYV. Outside the library a mobile van containing an "Oscar" satellite terminal was manned and demonstrated by K2REC and WB2AMX.

The show was very well attended by many people who were drawn in by newspaper, cable TV and word of mouth advertising over local repeaters.

K2LIO, LIMARC president, and WA2WKV, who organized the event for LIMARC, feel that cooperative effort by many radio groups such as this can bring much positive interest and credit to the amateur radio image.

Ed Piller W2KPQ

THE WHITE HOUSE?

Just a short note to compliment you on the mag. Arrival of *73* is the high point of my month. Unlike all other mags, every article in *73* is usually of interest to me rather than just 5 pages or so out of 150 pages. I am fairly knowledgeable in the field but I can't make heads or tails out of most of the stuff in *QST* and the others. Too bad *Hotline* went west — *HR Report* is really playing it up big in their ads.

It sounds like the gang at *73* really swings. You talk about things up there a lot and it has aroused the curiosity of myself and probably lots of others. How about a piece in *73* with pictures of the gang, pix of the *73* bldg, antennas, rigs, surrounding countryside, etc? We all would be very interested in this — sort of like a tour of the White House or something.

Well — thanx for the consideration. Maybe one man's opinion might be worth something. Really enjoy *73* — Star Trek communicators and all that.

Steve Uhrig WA3SWS
Columbia MD

UNLOCKING PLL'S

I wish to bring to the attention of Dr. Thomas A. Reilly and Calvin McCarthy, and any interested readers, that the book *Phase Locked Loop Systems*, published by Motorola and reviewed in the Nov/Dec 1975 issue of *73* under the heading "For Your Eyes Only," is no longer available.

Immediately after reading the review I sent off a check to Motorola for a copy of this book. I was extremely disappointed today to have it returned with a note that it is no longer available. For some time now I have been trying to obtain a book dealing with PLLs, but so far without success. If there are any readers/hams out there who may have a copy of this book and are prepared to part with it, please let me know for how much and I will remit the necessary amount. I would also appreciate knowing of any other publications dealing with PLLs that may be available.

Finally, let me compliment WØACR on his really great scope article titled "Eyes for Your Shack" in the same issue. It was really quite an achievement and a number of friends in this part of the world are considering duplicating it either in part or in its entirety.

SEA W

I thought I'd drop you another line on the status of CW in the U.S. Army. Just last year, the required level of proficiency for all CW radio operators (except for high speed *intercept* operators) dropped from 15 wpm to 10 wpm. It looks like in this day of microwave, troposcatter, and satellite communications, the need for HF communications (which is about the only place CW has a real advantage) is diminishing rapidly.

In contrast, my unit (Special Forces, or the "Green Berets"), who use HF almost exclusively, has upped

A Very Cheap I/O -- the Model 15

Contrary to the opinion expressed often in computer hobbyist publications, *Baudot is not dead!* It is alive and well, especially in Tyler, Texas! Frankly, I am glad I learned years ago not to believe everything I find in print. If I had, my Model 15 Teletype® would not be speaking BASIC today. I want to make it clear at the outset that this article is not intended to foster a Baudot/ASCII split among computer hobbyists. Nor is it written to argue the relative merits of one system over the other. I wish simply to demonstrate that a Baudot machine can be made an effective and useful hard copy peripheral in a hobby computer system.

Permit me to digress a moment from the main subject – Baudot – to comment in a more general way on these people we call "hobbyists." Although they come in many different varieties depending on interest and ability, there seems to be a common thread running between them: the need to be creative with their hands, heads, or both. For instance, there can be no greater pleasure for an electronic hobbyist than to sit back and watch his junk box creation perform like its "store bought" counterpart. At that moment he feels a sense of accomplishment unobtainable in many other pursuits of life. This "make do with what you have" philosophy is a reflection of the spirit that has brought man to his stately position among the world's lesser creatures. The hobbyist has the opportunity to foster this spirit each time he digs into his junk box for a new project. Unless you think I am only talking about an electronic junk box, let me remind you that a 16K word memory filled with NOPs is in a sense a junk box as well!

What does all this philosophical wandering have to do with Baudot? Simply this: There are people who say Baudot is obsolete and Teletypes that speak it are junk. Now, can't you see the eyes of some hobbyist light up when the word "junk" is mentioned? The very word carries with it a challenge he cannot resist. Out to the storeroom he goes to retrieve his old Model 15. The renewing of the hobbyist spirit has begun! There he goes . . . Watch him . . . Next stop Baudot BASIC!

About six months ago, a friend and I were taking just such a challenge. We have made quite a lot of progress since then. In our present state of excitement we want to share some of the knowledge gained and lessons learned. We hope our success will encourage some "junk box digging" by readers of *73.*

Getting Started

The best place to begin is in the pages of a book on Baudot Teletypes. One good choice is Wayne Green's *RTTY Handbook* (Tab Books). Learn the theory of teleprinter operation and become familiar with the different machines available.

Next, begin your search for a machine. This will probably require some footwork and a little time. If you live close to a large city start

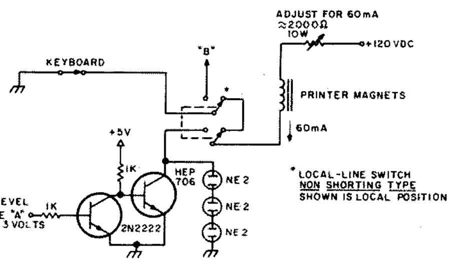

Fig. 1. Teletype interface circuit: Model 15 or similar.

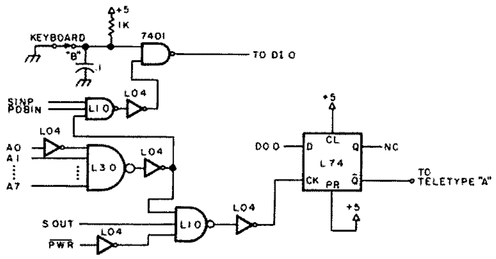

Fig. 2. Computer interface for software I/O. Labels reflect Altair 8800 bus. Points A and B refer to Fig. 1. All ICs are 7400 series – low power except 7401.

TELETYPE SPEED	PRESET COUNT 11	10	9	8	7	6	5	4	3	2	1	0
60 wpm	0	1	0	1	0	1	0	0	0	1	1	0
65 wpm	0	1	1	0	0	0	0	1	1	0	1	0
75 wpm	0	1	1	1	0	1	1	0	1	1	0	0
100 wpm	1	0	0	1	1	0	0	1	0	0	1	0

Table 1. Baud rate set up for Baudot Teletypes on Altair 8800 serial I/O boards.

by looking in the yellow pages under junk dealers and electronic surplus houses. Make a few phone calls, ask questions, and follow leads. There are mail order companies that have teleprinter equipment. Check the back pages and classified ads of amateur and computer hobbyist magazines. Write a few inquiries and get quotations – ask for the specific machine you want. Get in touch with local radio amateurs and see if they can help. Hams generally have a good attitude toward hobbyists of other persuasions and go out of their way to help. You might find a ham with a spare Teletype that he would be willing to loan out until you can get your own.

Give Western Union and Bell Telephone a call. If you can get through to the right people you may have a chance of getting a free machine. I have heard of this approach yielding success more than once. In these inquiries be sure to emphasize the "hobby" nature of your interest! Above all don't get disappointed and give up too soon. There are thousands of these machines out there – probably one with *your* name on it!

The Care and Feeding of a Model 15 (or Similar)

As the owner of a Baudot Teletype you should take some pride in your new possession. Over the years the Model 15 Teletype has gained an excellent reputation among people who appreciate well-engineered mechanical devices. Most of its moving parts are made of case-hardened steel. When a part does wear there is generally an adjustment somewhere to take up the slack. If you can find a maintenance manual, get it and use it. Your efforts will pay off in many years of reliable service. I have often heard Model 15 owners say not to worry with cleaning the working parts – the worse it looks the smoother it operates. A friend has a Model 15 with several more layers of dirt and grease than mine. Not only does his keyboard have a lighter touch but his printer is several decibels quieter! Remember to keep machine oil in the cups and on the clutch felts. With reasonable care your machine should serve you well for years to come.

The Interfacing Problem: At the Teletype End

Normally the Teletype will have two connecting cables: one for send (the keyboard) and the other for receive (printer magnet). For testing

Fig. 2(a). Serial I/O: Software technique for Fig. 2.

purposes the two can be series-connected with a power supply and current limiting resistor. Connected in this way the machine will type to itself. Teletype users call this "local loop" operation. For computer use the send and receive cables must be connected separately. Fig. 1 shows a transistorized switching circuit that provides the necessary TTL level signals for a computer interface.

The following notes refer to Fig. 1:

1. The use of a high voltage supply (100 to 120 volts) is recommended since it provides the simplest and most reliable operation. Of course, the driver transistor *must* be a high voltage type similar to the one shown.
2. Make certain that the local-line switch is a *non-shorting* (break-before-make) type. 120 volts is not a TTL level! A telephone type lever switch is ideal.
3. The printer magnets (usually there are two mounted side by side) can be connected in series or parallel. The circuit shown assumes a parallel connection. Adjust the slide on the power resistor for 60 mA in the magnet circuit.
4. Notice that in the local position the keyboard contacts are switching the full 60 mA at 120 volts. The contact arcing seems to do wonders for cleaning up noise problems in the keyboard. In the line position, the keyboard is switching to ground and the printer will accept TTL logic levels.
5. Make *absolutely* certain that the Teletype and all computer circuits share a good ground system. In fact, connect the Teletype chassis to the computer ground with a separate heavy wire. We have experienced ac transients on interface lines when the ground connection on the Teletype was inadvertently broken. On one occasion we lost some TTL in our Altair during such an occurrence.

Table 2. Baudot-octal conversion.

The Interfacing Problem: At the Computer End

There are several schemes available to perform the serial input/output function at the computer. A UART (Universal Asynchronous Receiver Transmitter) is readily adaptable to five level Baudot code. The UART represents a hardware solution to the problem. The serial/parallel conversion can also be handled by computer software. This simplifies the hardware requirement but ties up the CPU during input/output operation. The circuit in Fig. 2 and the accompanying software listing will illustrate this latter technique as applied in an Altair 8800 system.

Although the software I/O system is probably not a good long-term solution to your I/O needs, it does offer a quick and simple approach to getting your Teletype on-line. Fig. 2 is very similar to the interface circuitry necessary for a cassette interface of the Suding type. If you later change your I/O to a UART type, you can use this circuit to build up a cassette interface.

To check out the software I/O, make the following test:

1. At a memory location above the I/O routines, load a main program similar to:

```
        LXI SP, LOOP + 10
LOOP    CALL INPUT
        CALL OUTPUT
        JMP LOOP
```

2. EXAMINE the starting location of the main program and begin execution.
3. The printer should now echo keyboard entries.

In our Altair 8800 system we have used several home brew I/O interfaces with success. Our original circuit followed in design the "Basic Stunt Box" on page 299 of *RTTY Handbook*. This circuit was modified and improved through several generations. Most recently we have used a MITS SIOC interface board with a few simple modifications (see below). The MITS board is UART-based, with a software controlled interrupt scheme we have found very useful. Processor Technology's board is currently being used by Frank Corlett WA5BNK with his Altair 8800 and a Model 28. After a great deal of experimenting, we have little doubt that a UART-based I/O interface is best.

The MITS SIOC board was originally intended for use

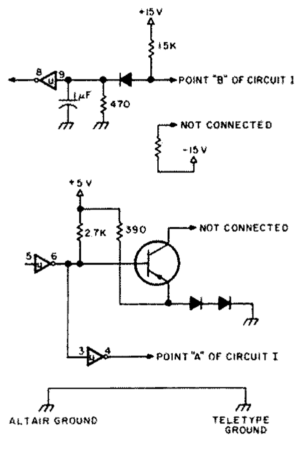

Fig. 3. Teletype drive circuits for MITS SIOC interface with modification for connection to a Model 15 Teletype.

with a Model 33 Teletype. To use it with a Model 15 or similar machine, make the modifications shown in Fig. 3.

In preparing the MITS board, the number of stop bits must be selected. The five level Baudot code consists of a start, stop and five coded data pulses. The start and data pulses are 22 ms each (60 word per minute machines) while the stop is 31 ms, about 1½ times the others. Theoretically, the stop pulse generated by the serial I/O circuit should be 1½ times the length of the start and data pulses. The MITS SIOC board has provision for 1 or 2 stop pulses only. Our experience has shown that both choices work satisfactorily. One stop pulse types a little faster than normal, 2 stop pulses a little slower. We have used the 1 stop bit set up for some time without any problems. A UART is available that provides the correct 1½ stop bits but we don't believe you need to be too concerned about getting one.

As you implement a Baudot system, knowledge of the Baud rate will be required. For instance, the MITS serial board instructions do not provide directly the Baud rate hookup for a 60 wpm Baudot machine. After a little head scratching we were able to figure out the circuit connections. For those contemplating a MITS board, Table 1 gives the necessary data for strapping the Baud rate counters. If you purchase some other I/O board, be sure to ask the manufacturer for details on setting the Baud rate for your Baudot machine. By the way, not all Baudot machines are 60 wpm. Some are 65 and 75 wpm. Gear sets are available from surplus dealers to change speeds. Model 15s work well at 75 wpm. Model 28s are 100 wpm standard.

How Does Baudot Look in the Computer?

The answer to this question depends upon the configuration of the interface system. Consider, for instance, a typical keyboard entry to the CPU accumulator. The normally closed keyboard contacts can produce a logic 0 or a logic 1 depending on the number of inversions that take place in the I/O interface. In addition, the interface circuit will determine the location and order of the five level code in the eight bit accumulator. As an example, consider the letter T as it might finally appear in the accumulator:

[T] * 020 001 017 036

These examples assume the lower five bits of the accumulator are used. A choice must be made from this group if standardization is to be achieved. After consulting a few sources, 020 appeared the best representation. The MITS and Processor Technology boards produce this representation. Table 2 presents the full Baudot character set as it would appear in octal notation.

For those not familiar with the Model 15s, upper or lower case is set by FGS or LTR keystroke respectively. A mechanical flip flop holds the case until another FGS or LTR keystroke produces a change. It is convenient in some systems to use a sixth bit to indicate which case is desired or the status of the machine. With the sixth bit, software can be written to control the FGS/LTR function. This relieves some of the difficulties encountered in keeping track of the case. An example will be presented subsequently. ■

---

*This bracket set will be used to mean the octal value of a five level Baudot character.

Code Converter Using PROMs

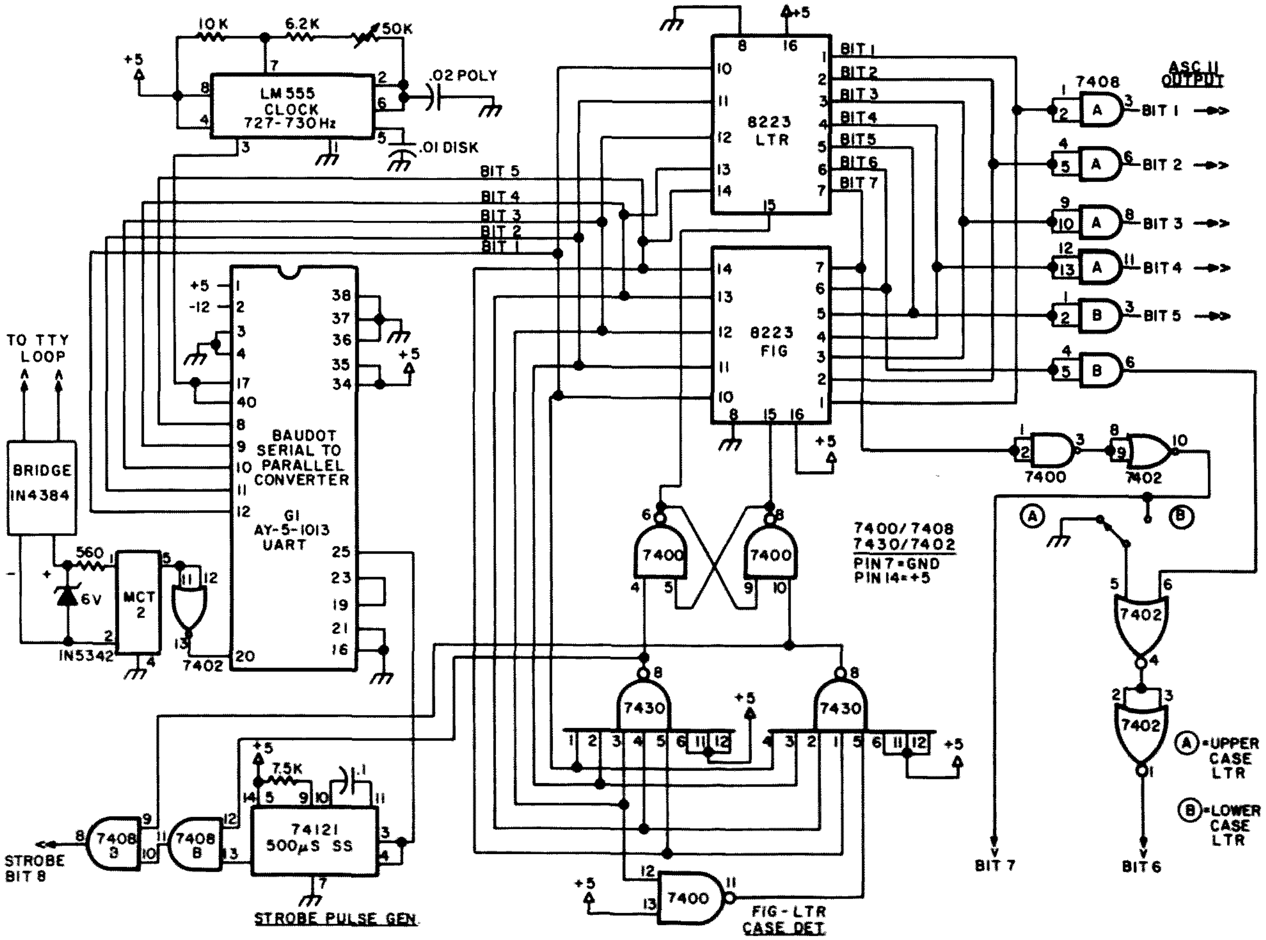

Fig. 1. Schematic.

Several amateur builders have advised me that they have had difficulty in obtaining the National 5220 BL/N code converter used in the RTTY TVT* unit. It seems that the supply houses do not want to sell them in single quantities, but only in three at a time. This makes the cost much too high and one is left with the problem of what to do with the extra chips.

Since it seemed that this was going to be a big problem in duplicating this circuit, I decided to redesign the circuit around a chip that is available in quantity and at a much lower cost. The 5220 BL/N costs almost $20 each, whereas the 8223 PROM surplus cost is around $3.00 each. The parts count was also reduced during the redesign. The 8223 PROM may be found in several surplus advertisements in *73 Magazine*.

The 8223 PROM must be programmed to do the code conversion. Several articles on PROM programmers were studied and the unit shown in the drawings was built in one evening. This code conversion provides all the Figures and Letters found on the Model 28 keyboard.

Circuit Description

The circuit is essentially the same as that used in the original RTTY TVT, but the 5220 BL/N has been replaced by two 8223 PROMs. DC pulses from the TTY loop are coupled to the UART through an optical isolator and inverter. The parallel output of the UART is connected to the 7430 FIG-LTR case detector and to the input of the two 8223 PROMs. The outputs of the PROMs are paralleled and connected to a buffer for output isolation. The upper and lower case letters feature was retained for use by the video readout circuit. The two 7430s are wired to recognize the FIG or LTR Baudot code and to trigger the 7400 FF causing a high to appear on pin 15 of the selected 8223. If the LTR key is struck, a high will appear on pin 15 of the LTR 8223 and a low will appear on pin 15 of the FIG 8223. The strobe pulse on the output of the strobe SS will also be inhibited. The Carriage Return, Line Feed, and Stop keys are programmed by the PROMs to present a blank signal to the TV video readout unit. The builder will also note that I have deleted the ROM input buffer and all pull up resistors.

Construction

The new code conversion board is the same size as the old one (4¼ by 6 inches). A layout of the board's major components and schematic are provided. A diagram of the programmer I built along with a layout of the front panel is also provided. The program for the 8223 when used in this code conversion unit is shown in Table 1.

I used point to point wiring for the circuit board. The pin connections on the connector were the same for both the old and new boards so I could check out my circuits with the least amount of fuss. I wired up the clock first and checked it for proper operation and adjusted it to the proper frequency for 60 speed operation. I then wired the input circuit to the UART and con-

Table 1. Code conversion table for programming the 8223 PROM in the Baudot to ASCII RTTY TVT.

nected the bridge into the TTY loop circuit. A check was made to assure that the parallel Baudot output code was appearing properly on pins 8 through 12 on the UART. The Strobe Pulse Generator was wired next and again checked to be sure that the 500 microsecond pulse was being generated when a key was depressed on the keyboard. The FIG/LTR case detector was then wired and a circuit check was made to confirm that pins 6 and 8 of the 7400 FF changed state when the FIG and LTR keys were depressed on the keyboard. Then the final wiring was made on the 8223s and the output buffers. The board was again plugged into the system and a check of all letters and figures was made to be sure that the PROMs were correctly coded. It all worked just as planned.

The PROMs have been programmed so that the RTTY TVT screen does not print any Greek alphabet garbage when the CR, LF and other selected non-wanted characters are struck. On the old preprogrammed 5220 BL/N you had a few Greek characters show up every time the FIG, LTR, Bell, or STOP characters were received or transmitted. When you do your own programming, you can prepare it so that this does not happen. Another blow for those who build their own gear.

This new version of the RTTY TVT code converter board should enable the builder to fabricate his unit with much less fuss over trying to locate hard-to-get components and in the process reduce the cost of the unit. ■

A Nifty Cassette - Computer System

The most practical and economical way to store programs and large quantities of data for small computer systems is with the common tape cassette recorder. Cheap and plentiful, audio-type cassette equipment is capable of storing several times the amount of data that an equivalent volume of paper tape can hold, with the added benefits of erasability and easier operation. Floppy disks may be faster, but are beyond the price range of most hobbyists.

While computer manufacturers and software houses have long been supplying their programs on audio cassettes, there has been a major problem with compatibility. Every manufacturer has had his own pet system of recording, and a tape recorded for use with one brand of computer is utter gibberish to another brand of computer. For this reason, several manufacturers decided to adopt a standard system of tape interfacing.

The proposed standard, as implemented by Pronetics Corp., calls for a frequency-shift keying standard not entirely dissimilar to that used for RTTY, but with several crucial differences. The two tones to be recorded are ideally to be square waves, with Mark (logic 1) to be 2400 Hz, and Space (logic 0) to be 1200 Hz. With a standard tape exchange speed of 300 baud (bits per second), Mark would consist of eight cycles, Space of four. This could be divided to 600 or 1200 baud, in which case one cycle would be a space (1/1200 sec). Higher density would be impractical. For comparison, 300 baud corresponds roughly to 30 characters per second.

Within each character, the first recorded tone should consist of a Space (start) bit, followed by eight data bits (least significant bit first, parity last) and two Mark (stop) bits. All undefined bits, as well as the interval between characters, would be Mark (2400 Hz).

This system has several beneficial features. It is self-clocking. The first bit of any character is Space and must follow the Mark tone that ends previous characters and exists between characters. It is possible to tolerate as much as a 30% speed variation with this system, which can be an important factor with inexpensive tape equipment.

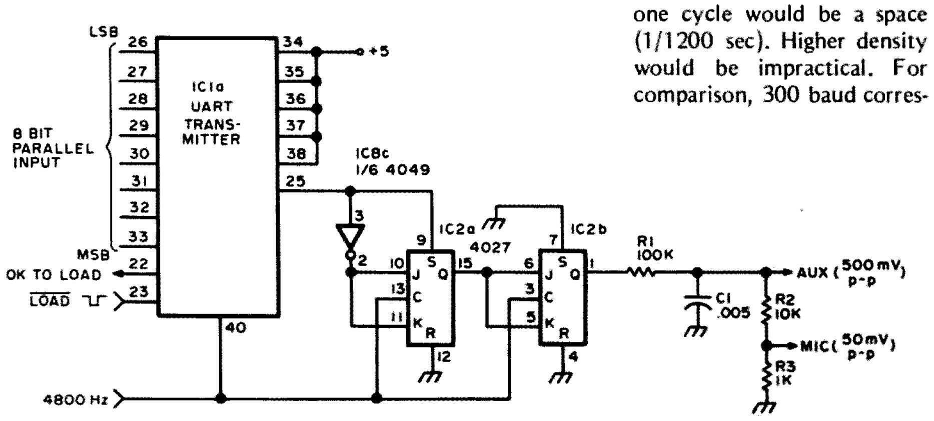

Fig. 1. Cassette digital modulator. This circuit converts 8-bit parallel input data to a series of 2400 and 1200 Hz tones for recording on cassette tape.

Do I Need a Good Recorder?

Almost any cassette recorder can be used for data storage using this FSK standard system. But for convenience and accuracy, there are a few criteria for selection that differ from hi-fi quality.

You want a clean, reliable machine. Dirty heads and mechanism can spoil data very easily. If you don't have a cassette recorder already, a used model is adequate, but it shouldn't show signs of mistreatment. It should also have capstan drive — a few miniature units don't.

A digital tape counter is also a great convenience. Without one, identifying programs on a tape can be difficult, and could lead to accidental erasures. These are found on many hi-fi type machines, and occasionally on portable units.

An important electrical feature is ac bias/erase. Some recorders, and most of the under-$100 category, use dc for erasing and record biasing. This results in higher noise and less frequency response. While frequency response is not as critical with this system as with music recording, it still helps to have a good clean treble response, which can help preserve the square wave shape. Low noise means fewer errors, so a high signal-to-noise ratio aids reliability.

Stereophonic capability is unnecessary. If you have a stereo recorder, be sure to record both tracks simultaneously, and bulk erase the tape before using it.

Your tape recorder must have an auxiliary or microphone input jack, as well as an earphone or line output. Acoustic coupling is unsatisfactory. The choice of levels can be performed in the computer interface circuitry, so either mike, line, or speaker levels can be used.

In a meeting organized by the staff of 73 Magazine, the microcomputer industry accepted this cassette system as the industry standard.

What About Tape?

While the choice of tape recorder is uncritical, the tape itself is the weak link in the chain. Do not skimp on tape. Use the best tape you can get your paws on. Since dropout on the tape means loss of data, the tape must have a high manufacturing standard. Some cassettes jam easily, and the thin tape found in C90 and C120 cassettes is too thin and fragile to be reliable. A premium grade C60 tape is ideal. Perfectionists might want to spend the extra money for chromium dioxide tape. The extra response can't hurt.

Store the tapes in a dust-free location, in their own container. Do not smoke near the tapes or the recorder, and clean the heads frequently. Tape cleanliness and quality are far more important in digital applications than in music.

The Recording Interface

Digital information from your computer is generally available as 8 bits parallel from either an I/O port or data bus. The tape is recorded serially; the conversion is best accomplished with a Universal Asynchronous Receiver/Transmitter (UART) IC.

The modulator is shown in Fig. 1. The serial output of the UART has logic 1 as a high level and logic 0 as a low level. IC2a and IC2b form a clock divider circuit, dividing the 4800 Hz clock signal by 2 or 4, depending on the UART output level. The output is a series of square waves which feed the tape recorder's input.

The poor frequency response of some tape recorders, especially those with dc bias, causes the manufacturers to exaggerate the treble being recorded, which distorts the square wave. Sine waves record better, but are harder to generate digitally. In some cases using a low pass filter makes the waveform usable; R1 and C1 perform this function. A smaller value for C1 may increase effectiveness with better recorders. Fig. 2 shows the effect of the recording process on digital waveforms.

The AUX output of the interface is 500 mV peak-to-peak and is for use with high impedance high level inputs. The MIC output is 50 mV, suitable for most units with microphone inputs.

The 4800 Hz signal must be capable of driving two TTL loads. While a crystal oscillator and divider chain work best, and a phase locked loop referencing the 60 Hz power line is also very good, the oscillator in Fig. 3 is simple and quite satisfactory (but requires calibration with a frequency counter).

If the available digital information from the computer is already in serial form with the necessary start and two stop bits, and is properly timed at 300 baud, the UART is not necessary. However, the 4800 Hz clocking signal should be synchronous with the serial data, with 16 clock pulses per bit. If the serial data is not at 300 baud, a UART receiver must first be used to convert the data to parallel form. It then is clocked through the UART transmitter as shown.

The OK TO LOAD line on the UART goes high when it is ready to accept a byte of parallel data. The data is then loaded into the UART transmitter by pulsing the LOAD line low for at least one usec or until the OK TO LOAD line goes low. The transmitter will then start transmitting the byte when the LOAD line is returned to the high state. When not transmitting, the output is high, causing the modulator to generate the 2400 Hz Mark signal.

The Playback Interface

There are several possible ways to recover the FSK signal from the tape. An FM discriminator or a phase locked loop demodulator can be used, just as with an amateur RTTY signal. Users of previous nonstandardized cassette interfaces can re-adjust them to decode the 1200/2400 Hz tones, but the most accurate system uses

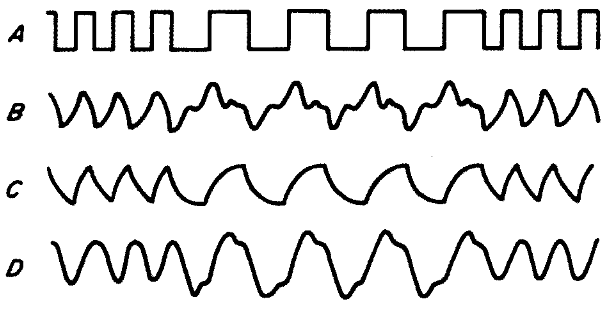

Fig. 2. If a square wave signal such as waveform A is recorded on a low cost cassette recorder, the playback response may look like waveform B, which is very difficult to demodulate. If the square wave is filtered with a low pass filter before recording (waveform C), the playback response will appear like waveform D, a usable signal.

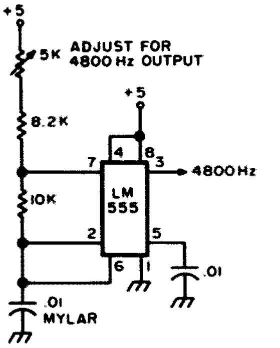

Fig. 3. Circuit of 4800 Hz oscillator. Use this circuit if a more precise and stable source of 4800 Hz is not available.

digital recovery to extract timing information from the recorded signal and uses that information to retime the recovered data.

Fig. 4 is a complete schematic of the playback demodulator. The signal from the cassette player is conditioned by IC3, an op amp used as a Schmitt trigger. The output of a Schmitt trigger is, by definition, either fully high or low, so it regenerates pure square waves from the distorted tape input. IC4 is a retriggerable one shot with a period set to 555 microseconds. As long as the input signal is 2400 Hz, the one shot is retriggered before it times out. Flip flop IC5a remains high, which is interpreted as logic 1. The 1200 Hz signal, on the other hand, has a period between pulses of greater than 555 usec, so the one shot times out, resetting IC5a. It stays at logic 0 as long as 1200 Hz is being received because the one shot is timed out whenever the next triggering edge occurs. When the 2400 Hz signal returns, the one shot stays high, permitting IC5a to switch back to high state. The output of this flip flop is the serial data.

While that simple circuit will work well if the tape speed is accurate to better than ±6%, such is frequently not the case. Since tape speed variations will be reflected in pitch variations in the recovered tones, it is possible to use the 1200 and 2400 Hz signals from the tape to retime the recovered data. Flip flops IC6a and IC6b extract this timing information. When the 1200 Hz signal is received, IC6a is preset with a pulse generated by C8 and R15 every time the one shot times out. The effect is to cause IC6 to divide by two. When 2400 Hz is being received, the one shot does not time out and IC6 divides by four. The result is a clock at the output of IC6b, at 600 Hz.

Instead of clocking the data into a shift register, the receiver portion of UART IC1 is used. It has built-in circuitry to identify the start and stop of each byte automatically. It also has three-state output (logic low, logic high, and functionally disconnected), which permits direct connection to most data buses and I/O ports. The UART needs a 16x clock, which is formed by phase locking a 4800 Hz oscillator to the 600 Hz output of IC6b. The PLL is adjusted to oscillate at 4800 Hz in the absence of any input signal. IC5b and IC9 divide the PLL output by 8 to drive one of the phase detector inputs, while the other input is driven by IC6b.

The UART receiver raises its DATA AVAILABLE output to logic 1 when it recognizes that it has received a complete character. Since the UART outputs are three-state, it is necessary to drive the RECEIVED DATA ENABLE input to logic 0 to read the parallel output data. After the parallel data has been read it is necessary to pulse the RESET DATA AVAILABLE line to prepare the UART to output the next byte. The pulse must remain at logic 0 for at least one usec, or until the DATA AVAILABLE line drops to logic 0.

Circuit Adjustments

The only adjustment necessary for the recording modulator is to put the 4800 Hz signal exactly on frequency. Since a Mark byte

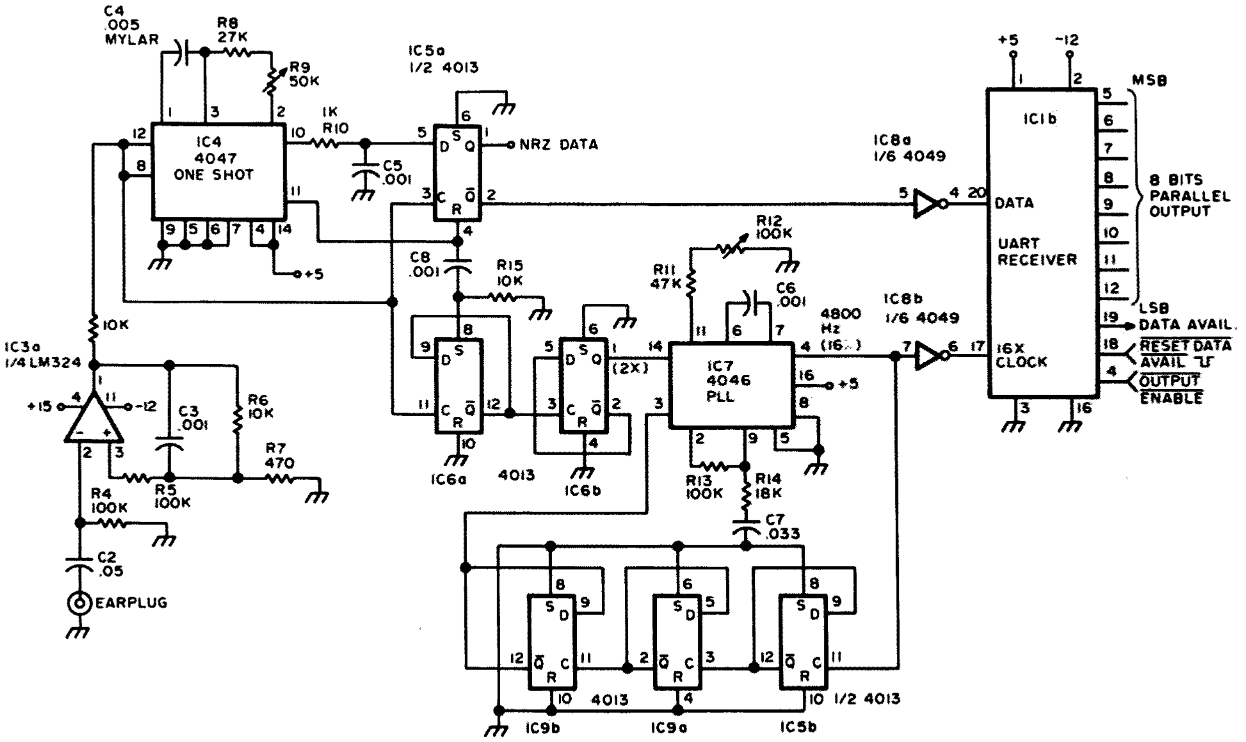

Fig. 4. Cassette data recovery circuit. Refer to text for circuit operation.

consists of eight (not seven or nine) cycles at 2400 Hz, this is fairly critical.

The data recovery one shot and PLL oscillator must be accurately adjusted for best results. The one shot is critical. To adjust it, set a well calibrated audio source to 1800 Hz with 1.5 to 3.5 V rms output. Adjust R9 until the data output of IC5a pin 1 just changes, measured on a high impedance voltmeter. Adjust R9 to as close to the point of change as possible.

The PLL oscillator is adjusted by R12 with no input to the playback input. If no counter is available, the oscillator output at IC7 pin 4 should be compared to the 4800 Hz signal used for the UART transmitter.

Circuit Operation

The circuit as shown will recover data most accurately if the earplug output signal of the tape recorder is between 4 and 10 volts peak-to-peak. Most portable recorders have that capability. If the cassette deck does not have a speaker amplifier, a low gain amplifier may be necessary. If the recorder uses dc bias, there may be too much treble, which necessitates turning down the tone control.

To comply with the standard for tape exchange, the recorded data should be preceded by at least 5 seconds of 2400 Hz tone before the data begins. This is accomplished by operating the recorder in the record mode for five seconds or longer before sending data to the UART transmitter. With the UART idle, the modulator generates 2400 Hz.

During playback, wait a couple of seconds before allowing the computer to accept the UART receiver output, to avoid reading the garbage generated by turning the recorder on and off. It is possible to have the computer control, via a relay, the remote control switch of the tape recorder under program control. It is still necessary to wait a few seconds before accepting data, due to the time spent starting and stopping the tape. The 2400 Hz leader provides that interval on the tape.

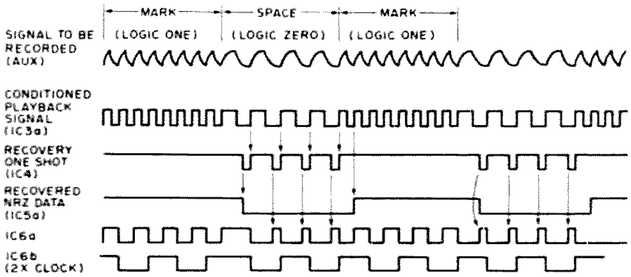

Fig. 5. Cassette modulator/demodulator waveforms.

Conclusion

Using this type of hardware for tape cassette modulation and demodulation simplifies programming for a cassette-oriented computer system. In some circumstances it may be possible to connect the interface hardware directly to the computer, while some computers may require peripheral interface adaptors to get the data in and out of the computer. ■

The cassette interface described here is manufactured by Pronetics Corporation. It is available fully assembled and tested on a 4.5" x 6.5" circuit card with standard edge connector. For price and other information write: Pronetics Corporation, PO Box 28582, Dallas TX 75228. – Ed.

Is Digital All That New?

To meditate on an experiment, a serious experimenter often shelves today's experiment, perhaps never to take it up again. The "light" was in the meditation and not in the experiment. This brings me to the point at hand – meditation as related to digital.

For several years now, a transition from analog to digital has been in the process. To many people, digital is considered as a rather new development, but I ask, "Is it really all that new?" The question may suggest the answer that digital has been around for some time.

Just for the fun of it, let us take a brief and somewhat abstract view of digital devices or communications through the age of man.

From man's beginning, he had a very good calculator at his fingertips as well as a computer with all the software that is necessary for its operation, although he had very little need for either in his primitive culture. It was 2 to 3 million years before man saw the need to communicate between computers. Man has, over the last 20,000 years, developed ways to communicate between computers.

If the old axiom is true that a picture is equal to a thousand words, and if we should equate the picture to a computer address and equate the thousand words to the memory of the computer, then the cave man had the basic idea in his cave drawings some 20,000 years ago. Programming his computer to accept more addresses (more pictures), he was able to develop a memory system called hieroglyphics, which used approximately 900 pictures. Up to this time man had almost exclusively used analog, which is called the spoken language. Hieroglyphic programming was too complex for most computers, so a much simpler system was developed using only about 24 pictures. Hierotics, as this system is called, was very effective digital-wise, but lacked the ability to communicate with analog systems. About 3,000 years ago a digital to analog and analog to digital system was developed. This system is often called phonic writing. Soon to follow was a digital system that was much more simple and was easily converted to analog. This system was made by the combining of the Phoenician phonic system and the Roman alphabet. Because this system had only 26 digits or letters and could be formed into word groups, it was adaptable to programming. Such programs are placed into a machine called a printing press and are read out into a permanent storage unit known as a book, which is a type of read only memory. With this type of ROM, the 2 or 3 million year old computer design has almost unlimited capacity to perform the most complex problems.

In Aristotle's theory of the universe formulated sometime around 400 BC, it was suggested that a binary system was possible. Such a system would consist of such variables as hot and cold, wet and dry, light and dark, etc.

Much experimenting in digital communications was taking place by the mid-1700s, parallel versus serial as each form was being developed. Static or friction electricity and its pith balls came first as a parallel system (i.e., one set of pith balls for each letter). Soon to follow was a synchronized serial form using only one set of pith balls.

Galvan electricity and the use of magnetic needles went through the same parallel and serial development. However, a new wrinkle was added. The new wrinkle was code – that is, left or right, operated or non-operated. Its form was much like that of Morse code.

From its inception in the mid-1800s, the electromagnetic (telegraph) system used a code in serial form. It was the search for the conversion of the electromagnetic digital system to analog that led to the development of the telephone – which just happens to be an analog device. It was only a few years ago that the conversion of digital to analog and analog to digital was electronically accomplished. Its form is called pulse code modulation.

Just as in the addressing of electronic computers, we have been simplifying the addressing to the 2 or 3 million year old design. Some examples include changing "The United States of America" to USA, and other conversions resulting in terms such as IRS, FCC, IBEW, NAACP, FBI, CIA, 73 and others.

What is the answer to the question, "Is digital all that new?" I would say no. I would go so far as to say that at present we are not really in a truly transitional period but rather in a sort of jockeying position. As we turn the corner, I predict that the next big development will be a 3D computer that will make the present computer look like a small contribution to the overall communications system – but I see no way that the old 2 or 3 million year old design will ever be replaced. ■

I/O EDITORIAL

from page 69

your own if you want to customize the programs to fit your exact needs or if you want to use the gear for some new application. Who knows, once you're set up you might want to score a ham contest and program your computer to cross check every reported contact on the incoming logs . . . that program would keep you out of trouble for a while. Or you might want to analyze Oscar contacts for anomalies to see if there are indications of over the horizon propagation at times.

The uses for your computer will be expanding constantly as you discover new things you want to do . . . and learn more about how to program the beast to do what you want. When you have worked several weeks in your spare time to perfect a program, you are on the one hand a bit reluctant to just give away all that work to anyone who comes along . . . on the other hand you are so proud of what you have accomplished that you want others to see how neat it is. I don't know how this will work out in the long run . . . perhaps there will be some programming sales services to help you get a small royalty for your effort . . . selling your program to those who want it for a few bucks. On the other hand, the magazines of the future may devote pages to new programs . . . we'll see.

Right now you can buy some programs on cassettes . . . such as BASIC Language . . . a ham package from The Digital Group . . . and a few things like that. Much more is available in printed form . . . *What To Do After You Hit Return* is a book full of game programs and sample runs of the games to give you the idea. Digital Equipment Corporation has a book (which they don't want us to sell) of 101 games in BASIC. Much of this is pretty much the same as the *What To Do* book which is published by People's Computer Company and is available for $6.95 from *73* . . . (ahem . . . commercial).

The people who are selling programs on cassettes get bent out of shape if you run off a copy for a friend. They spent a lot of time (which is money) writing the program and getting it perfected (debugged) and they feel that you are stealing from them if you don't pay the freight. A letter was just sent around to this effect by the chaps who developed the BASIC program for MITS.

Software such as the MITS BASIC program is usually copyrighted, but this is difficult to protect. It may be that programmers will develop some smarts in this line . . . perhaps taking a hint from map publishers. Every map you see that is copyrighted has some extra squiggles in the borders of a state or a country, or something which is not there in real life. Then, when you innocently take a gas company map and trace out the part you want and use it as an illustration for your article or in a book, wham! One large map maker pulls in over a million dollars a year in copyright infringement cases, I am told. The fact is that it is awfully difficult to explain why your map has that squiggle over there or perhaps an extra town that just doesn't exist (a Cleartype Map favorite) . . . particularly when the case is scheduled to come up in court soon.

Would it be that difficult to customize each copy of BASIC with a little identifying (but non-printing or operating) character? It would be hard to find and would make each copy of the program individually identifiable . . . and might put some teeth into contracts. Just an idea . . . I'm sure ways will be found to solve the software sales problems . . . of course it might happen that programs will eventually just be part of the hardware cost and be available essentially free.

Yes, with this software you will be able to get your computer to do a lot of nice things . . . like play games. But you will still have to learn how to do your own programming for anything off the beaten track. To put it into a percentage . . . argue with me if you like . . . figure 25% hardware . . . 25% language programming and 50% your own programming efforts. Once you get into computers you are going to have your hands full . . . and you will have a ball. You may even decide to go back to fresh orange juice.

The Ins and Outs of TTL

The design of digital circuits using TTL integrated circuits can be much less frustrating if some simple rules are followed. I am referring to the rules that dictate how and why interconnections between the various circuits and the outside world are made. If you follow the rules, you should be able to put together a digital circuit from TTL ICs and only have to worry about wiring errors, logic goofs, and bad ICs. The information is from the manufacturers' literature and my own experiences on the bench.

Ins

The most common and most easily overlooked input of TTL circuits is the power supply. One look at any TTL circuit and you quickly know the value of the supply voltage is +5 V. For those who worry about such things, the tolerance is ±5% (military versions are ±10%). In other words, the manufacturer only guarantees proper operation of his ICs when the supply voltage is between +4.75 V and 5.25 V. This is not to say they won't work at other voltages – only that there is no guarantee.

When TTL circuits switch they generate very high frequency current spikes on the power supply lines. These current spikes traveling through the high frequency impedances of the power supply lines cause voltage spikes which can couple into other circuits and trip flip flops, clock counters, and do all sorts of nasty (and very difficult to find) things. To protect yourself from this problem these power connection rules should be followed:

1. Connect a .01 uF disc capacitor from the +5 connection to the ground connection of each IC. Locate the capacitor as close as is practical and use short leads. A miniature disc with a voltage rating of 10 volts or more is a good choice.

2. Use fairly heavy wire (I recommend #18 or larger) for +5 and ground lines and

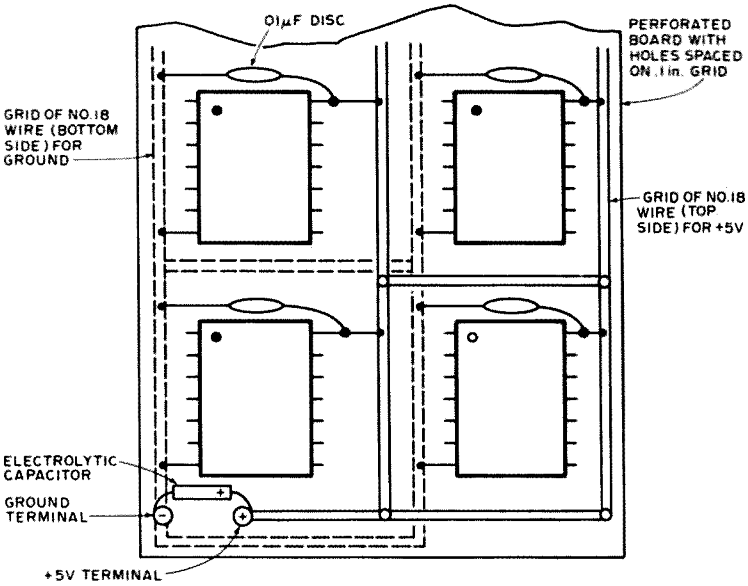

Fig. 1. Illustration of rules for power supply connections.

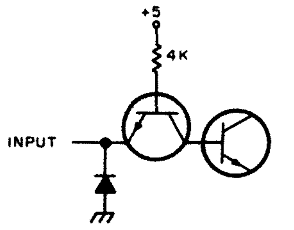

Fig. 2. Standard TTL input circuit.

arrange them so there are many connections. Try to simulate a ground plane and a +5 plane.

3. For every 20 ICs or so in your circuit put in one electrolytic capacitor from +5 to ground. Any value between approximately 4 and 25 uF and 10 volts or more rating is OK. If only one is used, try to locate it where the +5 first comes onto the board. If more are used, distribute them more or less evenly over the board.

4. Use a regulated supply for the +5 V. There are many circuits for making a regulated supply. Look at almost any article using ICs and pick one that suits your requirements.

Some of the above rules may seem obvious while others are not so well known, especially to the newcomer. Fig. 1 illustrates one method of construction employing point to point wiring following the above rules.

Next on the list of TTL "ins" let's investigate a typical input circuit as shown in Fig. 2. In order to guarantee that the transistor is turned on we must do two things. First, we must make the input voltage less than .8 V, and second we must draw out of the emitter 1.6 mA of current. In order to guarantee that the transistor is turned off we must also do two things. First, we must make the input voltage greater than 2 V, and second we may have to supply up to 40 uA of leakage current. The diode is not necessarily present in all circuits. Its purpose is to limit

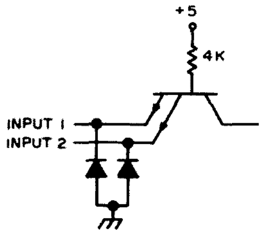

Fig. 3. Input circuit of 2-input gate.

negative pulses on the input that may occur due to transmission line effects on long interconnections. This input characteristic is called 1 unit load (UL) and a circuit such as Fig. 2 which contains 1 UL is said to have a fan-in of 1.

If a second emitter is added to the circuit of Fig. 2 we have a 2-input gate configuration, as shown in Fig. 3. Each input has its own protection diode. If either input satisfies the "on" requirements the transistor will be on. Obviously, both inputs must satisfy the "off" requirements in order to turn the transistor off. By adding more emitters the manufacturers make multiple input gates. The 7430, for instance, has 8 emitters.

What about the undefined area of the input characteristic which lies between .8 V and 2 V? It is just that, undefined. This is a "grey area" where nothing is guaranteed and, except for some special circuits (discussed later), it should be passed through as quickly as possible (less than 200 ns). If the input passes through this region too slowly the output can actually break into oscillation. In fact, this is how a TTL oscillator gets started: by being biased deliberately into this "grey area" until oscillation occurs and then having the frequency of oscillation controlled by external components.

Inputs from the Outside World

TTL circuits connect to

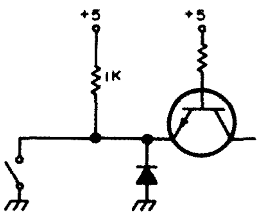

Fig. 4. Using a normal switch to drive TTL.

themselves very nicely, but the outside world is not necessarily TTL compatible. How do you satisfy the input requirements outlined above? It is very easy to get a voltage less than .8 V and able to sink 1.6 mA: Just short the input to ground with a switch. What about the other limit? How do we get the high voltage and current source? Fig. 4 shows one way. The 1k resistor guarantees that even with 40 uA being drawn, the voltage will be above the required 2 V minimum.

When the input is relatively slow in changing you can avoid the "grey area" problem by using TTL ICs which have a special hysteresis built into them. These are called Schmitt triggers and have different switching points depending on whether the signal is positive or negative going at the time. The 7413, 7414, and 74132 are examples of this Schmitt trigger type of circuit.

When considering switches as the connection to the outside world another potential problem arises. The contacts of the switch don't close "cleanly." They actually hit and bounce apart one or more times before remaining closed. Normally this is no problem, but if you were attempting to count switch closures it would not be possible. Fig. 5 shows how to use an SPDT switch and two NAND gate elements to form a flip flop which debounces the switch. This is a very common form of circuit configuration called cross-coupled NAND gates.

Often when you are finished with a logic design you will find yourself with unused inputs to some circuits. *Never*, repeat, *never* leave any unused input to float; it will cause nothing but trouble. Even though an open input is theoretically the same as a high, in practice it is very sensitive to any kind of noise and can cause the output to change for no apparent reason.

What do you do with unused inputs? There are several choices:

1. If it will not prevent normal operation of the circuit you can ground the unused input or connect it to a high source.

1a. The high can be obtained by connecting directly to +5 V. The manufacturers don't recommend this since, if the input goes above +5.5 V, it is possible to damage the input if the current is not limited in some way. I do it all the time with no problems (yet). I recommend connecting to the +5 V connection on the chip itself.

1b. Connect the unused input to +5 V

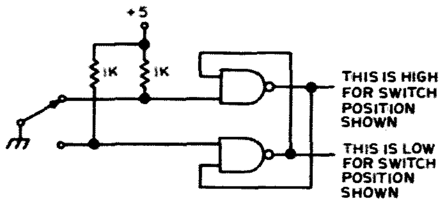

Fig. 5. Using cross-coupled NAND gates to debounce a switch.

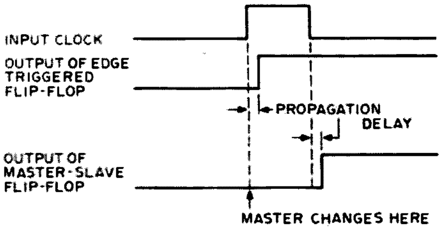

Fig. 6. Timing diagram showing difference between edge-triggered and master-slave flip flops.

through a 1k resistor. One resistor can tie as many as 50 inputs to +5 V.

1c. Use an unused inverting element and ground the input(s) to force the output high. This high output can then be used to pull up as many inputs as its fan-out is rated (see output section).

2. Unused inputs of gates can be connected in parallel with used inputs. There is no increase in load for low inputs. The total current required for the two inputs in parallel is still 1.6 mA. Actually you can tie as many in parallel as you wish and the total low fan-in will not exceed 1 UL. The high fan-in does increase, however, as each emitter may require the 40 uA leakage current. As long as the high fan-out capability of the driving circuit is not exceeded you can parallel gate inputs.

One more input characteristic of TTL circuits is worth mentioning. This is the difference between so-called edge-triggered and master-slave flip flops. The outputs of both circuits react according to the status of the control lines at the time the clock pulse occurs. An edge-triggered flip flop output reacts essentially immediately. The small delay is called propagation delay. A master-slave flip flop is more subtle. On the leading edge of the clock pulse the master reacts like an edge-triggered flip flop. The output, however, is from the slave and it does not react until the trailing edge of the clock pulse. Fig. 6 shows this difference in graphic form. The main point to remember is that a master-slave flip flop requires a complete clock cycle, not just one edge.

Outs

There are three basic forms of output circuit used in TTL. The most common form is shown in Fig. 7. This is the so-called totem pole configuration. In the low output state the bottom transistor is on and the top transistor is off. The bottom transistor sinks the current from the connected inputs. In the high state the bottom transistor is off and the top transistor is on. The top transistor now supplies the leakage currents for the connected inputs. This is the normal version. There are minor variations on this circuit but they all operate the same way.

The number of unit loads an output can drive is called its fan-out. The standard TTL IC has a low fan-out of 10 UL and a high fan-out of 20 UL. In other words, a standard TTL output can sink 16 mA (10 times 1.6 mA) and the output is guaranteed to be no higher than .4 V or it can source 800 uA (20 times 40 uA) and the output is guaranteed to be higher than 2.4 V. If you compare these output specs with the input specs you will find there is a .4 V safety margin.

There are several ICs which are specifically designed to drive larger loads. The 7437, 7438, 7439 and

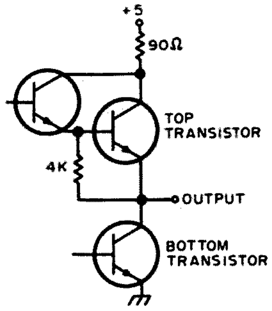

Fig. 7. Totem pole TTL output circuit.

7440 will all sink 30 UL. The 7437 and 7440 will also source 30 UL.

The 7438 and 7439 belong to another class of output circuit called "open collector." In this configuration the top transistor is missing and the bare collector of the bottom transistor is brought out. With this circuit you need an external load resistor of some sort to provide the pull-up to +5 V. If the voltage rating of the IC output is high enough (the 7407 is rated for 30 V, for example), you can switch much higher voltages, and even drive relays and lamps if the current rating is not exceeded.

The open collector circuit is also used in a logic configuration known as both "wired-and" and "wired-or." Fig. 8 shows how this works. All the open collector outputs are tied to a common pull-up resistor. If any output goes low they all go low (wired-or), and the output will only be high when all the output transistors are off (wired-and, hence both terms). There is a practical limit to how many outputs you can connect together. The pull-up resistor must supply the leakage current for all inputs and all outputs when they are all off and still maintain the voltage above 2.4 V. However, it must still be large enough to limit the total current of resistor plus inputs to 16 mA (10 UL) when any output is on.

Contrary to what you may have read previously, it is OK to connect TTL outputs in parallel, provided you also connect the inputs in parallel so the outputs are doing the same thing at the same time. In fact, the manufacturers recommend this technique as one way to increase fan-out when the load is too much for one output. However, you should restrict this paralleling to elements in the same package because large transient currents are generated and can cause problems if they are not closely confined.

The third and newest type of output configuration is the so-called tri-state or 3-state output. This is a normal TTL totem pole output where both transistors can be turned off. An extra "enable" input

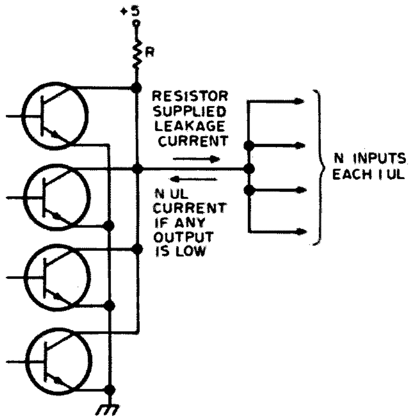

Fig. 8. Using open collector outputs for wired-or configuration.

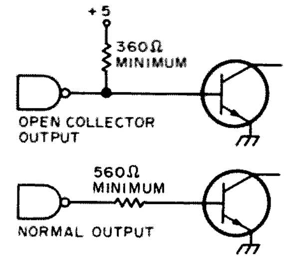

Fig. 9. TTL driving transistors.

is added to the circuit and when enabled the output functions as a normal TTL output. When disabled the output is essentially disconnected. This allows one common wire with many tri-state outputs connected to it to carry all sorts of different information (even in different directions) on a time division multiplex basis. All you have to do is enable the appropriate outputs and inputs at the proper time. This "bus structure" is very common in the world of computers and microprocessors. I have used tri-state circuits to latch 336 bits of data at one time and then output them 8 bits at a time. That is 42 different outputs on each data line.

Someplace in your design you have to connect outputs to the outside world. There are special ICs for driving displays of different kinds as this is one of the most common outputs encountered. I have also mentioned using high voltage open collector outputs. If you need more current or voltage, you can use a circuit such as shown in Fig. 9. In both versions the resistors limit the base current to a safe value. When driving an external circuit of any kind it is best to use an output dedicated to only that load. That way, if any stray signals are picked up and fed back on this line to the outside world they won't be able to couple into another input and disrupt operation. Also you should never use the output of a flip flop (this includes counters, shift registers, etc.) to connect to the outside world. It is too easy for a stray signal to sneak back, get inside the flip flop, and do weird things.

When it becomes necessary to switch large output loads, often there are transients generated that ride back in on the ground and cause stray triggers of flip flops and other nasty things. A relatively new circuit element called an opto-isolator eliminates this problem completely. Even when driving all 8 channels plus sprocket advance of a high speed paper tape punch there is no problem – and that represents 9 A at 24 V every 9 ms. The opto-isolator (see Fig. 10) consists of an infrared LED and phototransistor. The LED is driven from an open collector output and its energy is coupled optically (no physical connection) to the phototransistor, which is then used as a low level switching stage in a totally electrically isolated circuit.

The preceding rules and suggestions will not eliminate all your digital logic problems but they will greatly reduce them, especially those frustrating random ones. Remember the manufacturers only guarantee proper operation if you stay within the specs. Exceed the specs and all bets are off. ■

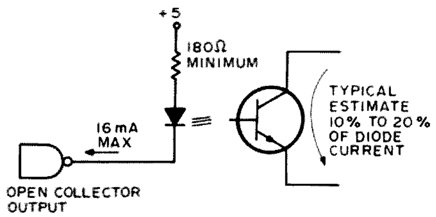

Fig. 10. Using an opto-isolator.

the requirement to 18 wpm — an interesting contrast!

Another interesting note — a *Stars and Stripes* article (I wish I'd saved it) of a few weeks ago told of the Navy having trouble coordinating with an allied nation's navy because none of the navy radiomen could handle CW — and the foreign navy didn't have our fancy RTTY and digital equipment!

At any rate, congratulations on a great magazine, Wayne, and I hope you get the bugs caused by the size change worked out soon.

DOING YOURSELF OUT

I thought I would enclose a quick note along with my reader service requests to tell you what a great mag you put out. Anyone with an interest in amateur radio, and with your new section on microprocessors, would be doing himself out of a great deal of enjoyable reading by not subscribing to *73*. Keep up the good work.

Bruce McCreath VE3EAR
Goderich ONT

TO THE TROOPS

Got my brand new format *73* yesterday over here at APO 09189 (southwest Germany), and I must say that I am impressed! I really like the new size, even though I was skeptical when I first heard that you were switching over.

Really a nice idea to have the Heath and the Hickok catalogs within the same covers. The new *73* is even better than before, and I have taken steps around my house to convert my bookshelves over to the new *73*. I appreciate the skill and preplanning that went into your conversion as per page 3.

Kinda feel for a guy like Fred Lichtgarn who is quitting before starting.

The new *73* made it to my APO, and then to me, in beautiful condition, so your mailer system is working fine.

Many thanks Wayne, and to the troops at *73*, who continue to keep better and better *73*s coming this way!

AIR BLUSH

I am writing to confirm your claim for the efficacy of your tapes (code). They have worked for me. I cannot truthfully give you the exact number of hours I used the 5 wpm tape, but I will approximate it at 6 hours, over a period of a few weeks. After that time, I joined a ham radio class at Cerritos College, Cerritos, California. The instructor, Roy Tucker K6UZB, has his own code tapes to loan to the students. I tried his and found them too simple, since after five weeks of class sessions I passed the test run for the Novice code. I believe that it was my previous study of your tape that made this possible, plus the fact that I am a musician and am quite accustomed to listening for rhythms and memorizing them. It was not difficult for me at all. I am presently working on upgrading to a General license (hopefully) and am just starting on the 13 wpm tape now. I will attempt to keep a check on the length of time it takes to achieve this speed. You may also find it interesting to know that Mr. Tucker uses the same principle that you do of recording the code character at 13 wpm and increasing the spacing between for ease of identification. He adds the device of naming the letter it represents. This is good at the start, but becomes irksome.

There is something else on my mind, Wayne. I feel I have something to say to your readers from the point of view of a white, female Caucasian, presently 53 years of age, married, the mother of two girls, and a successful pianist and teacher. I was dragged into this radio thing by my husband, who was formerly a ham and had dropped it as a young man. My attitude was pretty bad — the best you could say about it was that I was ambivalent and couldn't see the point of it for myself. It was obviously good for my husband, and I was touched that after 16 years of marriage he still wanted me to share his interests. I simply

Continued on page 154

NEVER SAY DIE

EDITORIAL BY WAYNE GREEN

from page 4

charge admission to the same party . . . or you may not.

Be sure to have someone with imagination and some business experience with relatively large sums of money involved so you don't penny ante the hamfest. You are working with thousands of dollars, so you can't afford to be too stingy on things. If you pull it off well, you will be able to keep the hamfest going year after year, building up in displays and hamfesters.

How about some articles on successful hamfests to spur interest in this activity?

VHF ENGINEERING

Bob Brown W2EDN, just back from one of the Windjammer cruises of the Caribbean, is really hot for a good design engineer to help him work up some new products. If you know of anyone who likes to do that sort of "work," have them get in touch with Bob. Bob is looking for someone with a lot of background in PC board layout and design . . . and he's got a darned good salary ready for someone. The Binghamton area is a nice one . . .

I gather that Bob and his family enjoyed the cruise . . . we've been advertising them in *73* off and on and had quite a few enthusiastic letters and calls from happy cruisers. They are strictly informal and low key . . . almost do-it-yourself vacations.

73 IS LOOKING, TOO

We're still in need of someone with a good ham background to help put together books. A good technical background will help us will an ability to write. And New Hampshire is even better than Binghamton for living. You could do worse.

As long as you have to work for a living, why not work in your major hobby and enjoy every minute of it? And as long as you have to live, why not live where others come for vacation all year 'round?

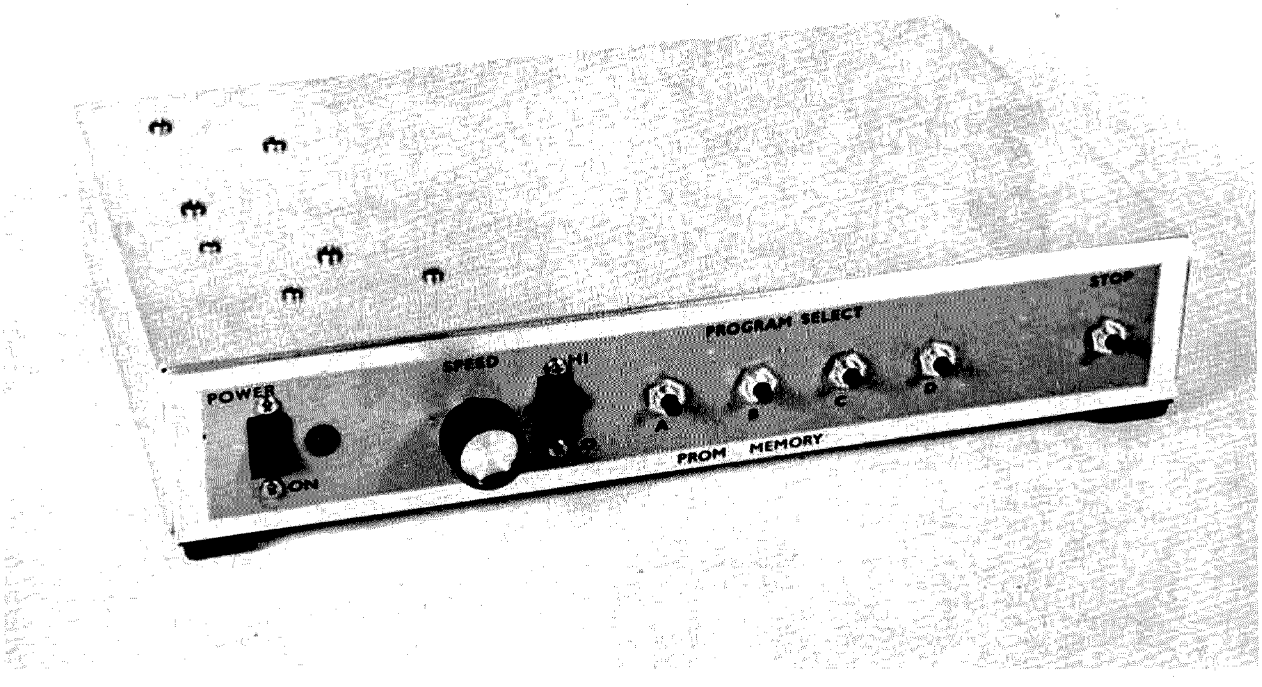
Build a CW Memory

While building a random access memory (RAM) for my keyer, it occurred to me that my CW operating habits did not require the versatility of the RAM and that my memory requirements could be satisfied with one or more programmable read only memories (PROMs).

Although the control logic for the read modes are similar for RAMs and PROMs, PROMs offer a non-destructible memory (within their recommended operating parameters) after their initial programming,



without the need to frequently refresh the memory as is necessary with RAMs.

The memory described is self-contained and need not be used with a keyer. The output circuitry is designed to drive grid-block keyed transmitters with key-up voltages not exceeding −100 volts. TTL inputs are available for keying the transmitter from an external source (i.e., the digital output from additional memories, a keyer, or CW identifier).

Circuit Description

Fig. 1 shows a simplified block diagram of the PROM memory. The memory uses four Intersil IM5600C PROMs. These PROMs are fully decoded TTL Bipolar 256-bit custom programmed read only memories organized as 32 words by 8 bits (U7-U10). Open collector outputs and chip enables insure simple memory expansion. An effective memory capacity of 1024 bits is obtained by ORing the four 256-bit chips together. I chose a 256-bit PROM because it offers a convenient memory length of approximately 22 characters. Memory retrieval is initiated with the appropriate program select push-button switch (S2-S5). The program can be stopped at any point with the stop push-button switch (S1).

U3 and U4 are 7476 Dual J-K flip flops with preset and clear, used as start/stop flip flops. The stop push-button switch, S1, is connected to the preset inputs (pins 2 and 7) of U3 and U4. Grounding this bus forces the Q outputs to logic 1, disabling the clock and U6, stopping the program (a logic 1 on pin 7 of U6 forces pin 5 low). The clock inputs (pins 1 and 6) are connected together. A negative edge at the clock inputs, corresponding to the end of the 256th bit, will clock Q to logic 1, disabling the clock and U6, ending the program. Individual program select switches are connected to the clear inputs (pins 3 and 8) of U3 and U4. Grounding *one* of these pins will start the program corresponding to the PROM selected. The Q outputs of U3 and U4 (pins 11 and 15) are connected to the chip enable inputs (pin 15) of the four PROMs. The appropriate PROM is enabled by forcing one of the outputs of U3 or U4 to logic 0, enabling the clock and U6, starting the program. Starting the program resets the eight bit binary address counter U1 and U2.

U1 and U2 are 7493 TTL MSI 4-bit binary counters used to address PROMs U7-U10 and U6, a 74151 TTL MSI 8-line-to-1-line data selector. The first three bits from the counter address U6, while the remaining bits address PROMs U7-U10. In this fashion U6 multiplexes the PROM outputs of eight lines to one line before the address counter selects the next word.

U5 is a 7420 TTL Dual 4-input positive NAND gate. It is the enable/disable gate for the clock and U6 and the reset gate for the eight-bit binary address counter. U11 is a 7403 TTL Quadruple 2-input positive

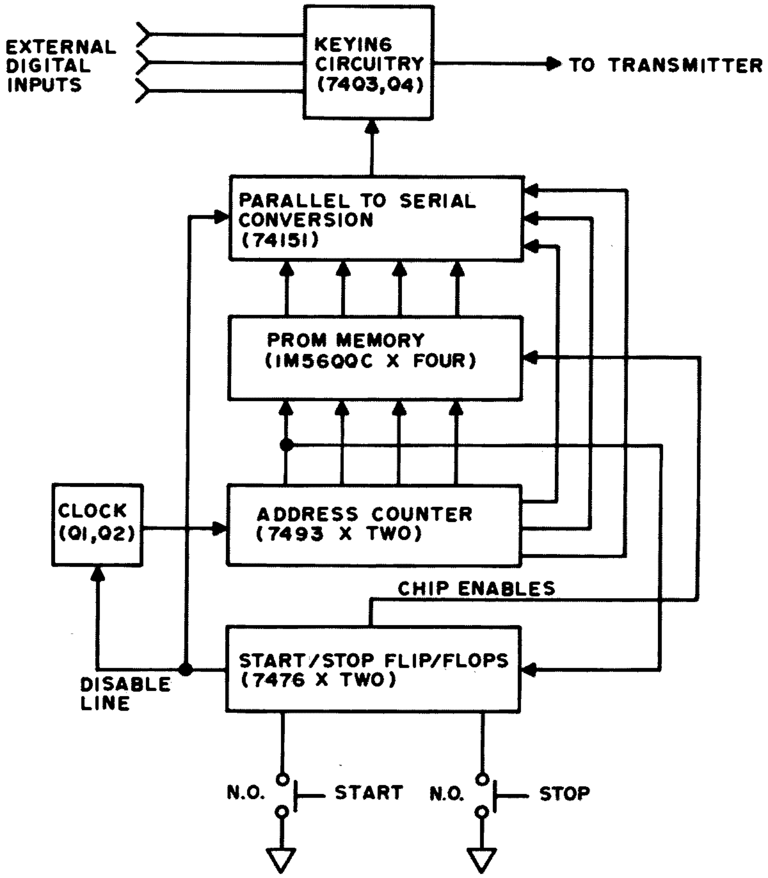


Fig. 1. Block diagram of the PROM CW generator.

NAND gate with open collector outputs used as the input for the transmitter keying circuitry.

Clock pulses for the memory are generated by a relaxation oscillator consisting of Q1 and Q2 and associated parts.[1] The oscillator is the same one used in my keyer and was selected so that the speed controls could be ganged and would track in the event that the keyer would be packaged with the memory (it wasn't).

Programming

PROMs are fabricated with all logic levels at zero. The programming procedure open-circuits metal links which results in a logic 1 at selected locations in the memory. Intersil, instead of using a metal link, forces a resistive shaft through the junction of one diode in the memory cell resulting in a logic 1 at selected locations in the memory. Once the memory cell has been programmed to a logic 1, that bit cannot be altered (reprogrammed).

Distributors of PROMs offer custom programming services or the reader may program his own. Design data sheets and application notes describe the programming procedures in detail.[2] Read these instructions carefully and fully understand the address methods as programming errors can be costly.

Fig. 2 illustrates a typical programming card for the following program: DE WA6VVL WA6VVL WA6VVL K. Standard spacing should be used in writing the program. For example, use 7 bits for a word space, 3 bits for a letter space, 3 bits for a dash and 1 bit for a dot.

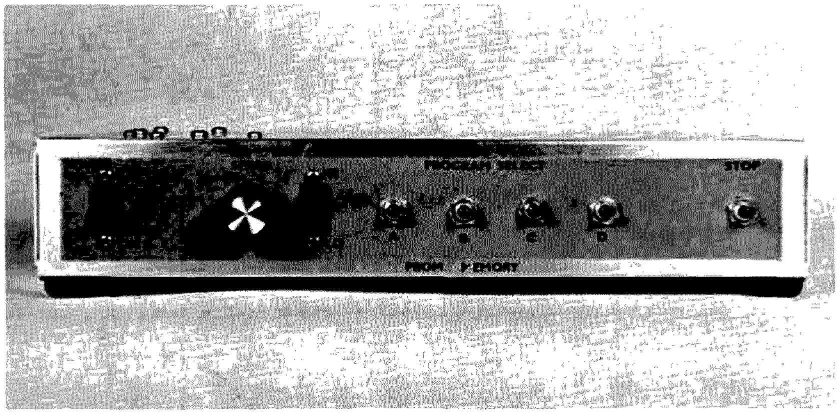
The quoted price from R.V. Weatherford included programming costs. One advantage of a distributor programming your PROM is that they verify its program before they send it to you.

Power Supply

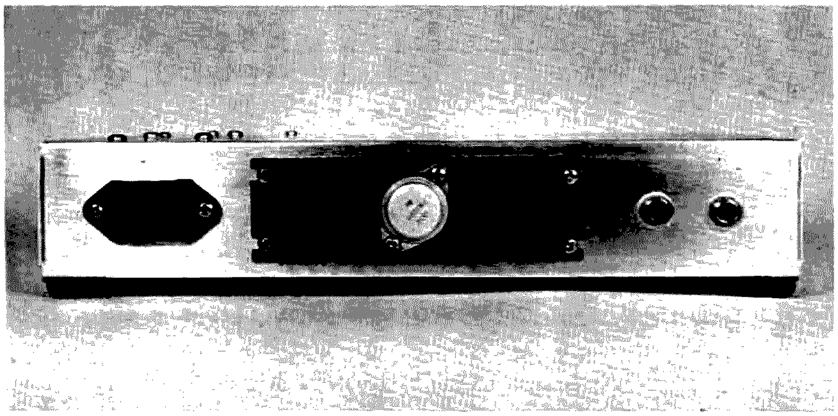
The 5 volt supply illustrated in Fig. 3 can be built to satisfy the requirements of the memory circuitry. U12 should be mounted on a heat sink similar to the Wakefield 680-.75A or 621-A.

U12 dissipates only 1½ Watts at nominal line using a 6.3 V transformer. However, at low line, ripple feeds through the regulator. No problems with the memory have been experienced under low line conditions to date. A slight improvement in low line operation can be gained by using a 12.6 VCT transformer and a full wave center-tap rectifier.

If you anticipate using your keyer with this memory, do not attempt to power the memory circuitry from your keyer power supply unless it is capable of supplying an



The program is selected with the appropriate program select push-button switch A, B, C or D. The program can be stopped at any point with the stop push-button switch. A single 20k speed control can be used and the HI/LO switch deleted.



U12 is shown mounted on its heat sink. The two open-circuit phone jacks are connected in parallel, providing an input for the author's keyer and an output for the transmitter. A line cord and grommet may be substituted for the 115 V ac connector.

additional 450-650 mA.

Construction

The memory is housed in a Cal Chassis 7" x 11" x 2" aluminum chassis base. The majority of the memory components are mounted on a single-sided 8" x 5" glass-epoxy circuit board. The board is fabricated to fit a standard 22-pin card edge connector.

Since the memory utilizes four PROMs in

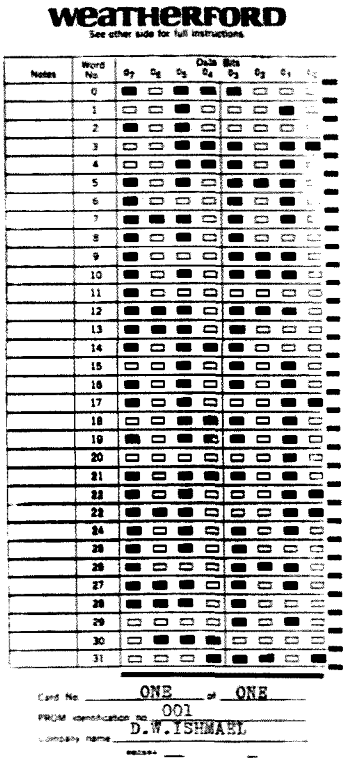


Fig. 2. Programming card (65%). The above program, DE WA6VVL WA6VVL WA6VVL K, is read from right to left, top to bottom. The program is written in the same fashion.

Weatherford P/ROM Programing Card

Ordering Information

1. Company name D.W.Ishmael
2. Company address 1118 Paularino Ave.,Costa Mesa, Calif
3. Requisitioner's name Above
4. Telephone number (714)979-5858
5. P/ROM manufacturer's part number IM5600C
6. Quantity of P/ROMs required 1
7. Quoted price per P/ROM $6.00
8. Requisitioner's purchase order number
9. Special P/ROM marking instructions 001
10. Shipping instructions UPS

How to use this card

1. Use a soft pencil (No. 2)
2. On the "program" side of every card mark blank spaces for the logic "1" (high output state) data-bit locations in your program.
3. Write anywhere on the shaded portion of the card. DO NOT mark in the unshaded portion unless you are indicating a "1" data-bit location.
4. DO NOT ERASE in the unshaded data-bit portion. If an error is made, destroy the card.
5. On card No. 1 of each program, complete the "Ordering Information" section above.
6. Pack cards with stiff backing to avoid damage.

Take completed cards to your nearest Weatherford sales office or send to:
Weatherford Programing Center
6921 San Fernando Rd.
Glendale, CA 91201

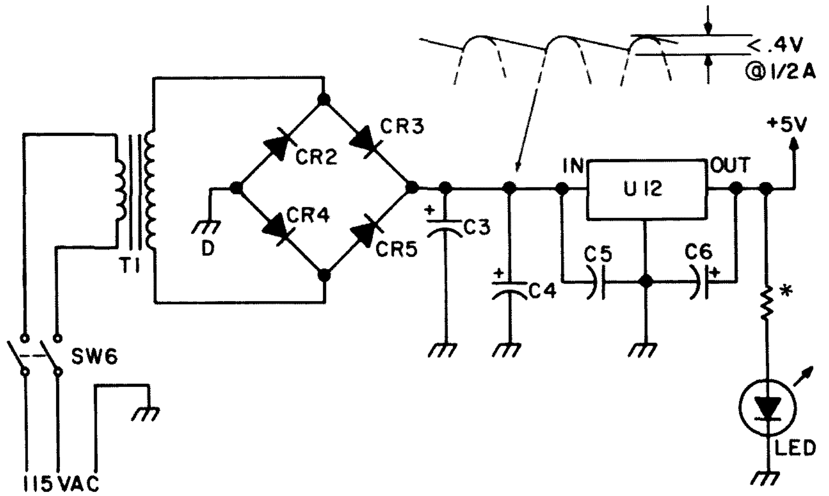

Fig. 3. Power supply. *Select for appropriate current through LED selected. 150 Ohms was adequate with a Hewlett-Packard 5082-4440 LED.

Parts List

C1	4.7 mF 10 W V dc tantalum capacitor	R12	2700 Ohm ½ Watt carbon resistor
C2	.001 mF ceramic capacitor	R13	10,000 Ohm 2 Watt linear taper potentiometer
C3-4	4700 mF 16 W V dc electrolytic capacitor	R14	82 Ohm ½ Watt carbon resistor
C5	.33 mF ceramic capacitor	R25	10,000 Ohm ½ Watt carbon resistor
C6	2.2 mF 10 W V dc tantalum capacitor	SW1-5	Normally open push-button switch. Similar to Alcoswitch MSPS-103C SPST.
C7	.1 mF 10 W V dc disc ceramic capacitor		
CR1	1N914 silicon signal diode	SW6	DPST miniature rocker switch. Similar to Alcoswitch MSL-203N-7.
CR2-5	1N4001 or equivalent 50 V piv rectifier diode		
Q1	2N5086 or equivalent PNP transistor	T1	6.3 V ac Filament Transformer, 1 A. Similar to Allied 6K9HF or Triad F-14X.
Q2	2N5961 or equivalent NPN transistor		
Q3	2N5224 or equivalent NPN transistor	U1-2	7493 TTL MSI 4-bit binary counter
Q4	2N4888 or equivalent HV PNP transistor	U3-4	7476 TTL Dual J-K flip flops with preset and clear
R1-R5,R16	470 Ohm ½ Watt carbon resistor	U5	7420 TTL Dual 4-input positive NAND gate
R6,7,15,17-24	4700 Ohm ½ Watt carbon resistor	U6	74151 TTL MSI 8-line-to-1-line data selector
R8	22 Ohm ½ Watt carbon resistor	U7-10	Intersil IM5600C 256-bit PROM
R9	27,000 Ohm ½ Watt carbon resistor	U11	7403 TTL Quadruple 2-input positive NAND gate
R10	39,000 Ohm ½ Watt carbon resistor	U12	7805 or LM309 Three terminal regulator
R11	15,000 Ohm ½ Watt carbon resistor		

parallel on a single-sided board, there are a number of jumpers (92) and holes (434) on the circuit board. The jumpers are installed first with the rest of the components following. Sockets are advisable due to the cost of the integrated circuits and PROMs. They not only speed troubleshooting when the need arises, but also prevent overheating during the soldering operation. The power transformer, filter capacitors, regulator, panel switches and controls are mounted on the aluminum chassis.

Total assembly time for the board, including drilling the holes, was under 4 hours. Mechanical and chassis wiring consumed another 10 hours.

After assembly, connect pins 1 and 20 together on the connector. This connects the digital output of the memory to the first input of the transmitting keying circuitry. If there are no additional inputs, ground pins 2, 3 and 4.

After checking the power supply voltage, connect the power supply, start/stop push-buttons and speed control, and the memory is ready for use.

Two open-circuit phone jacks have been provided on the rear apron of the chassis. They are connected in parallel providing an input for my keyer and an output for the transmitter.

Turn the PROM memory on "off the air" as it will take a few seconds for the memory to clear itself, the actual time dependent upon the setting of the speed control.

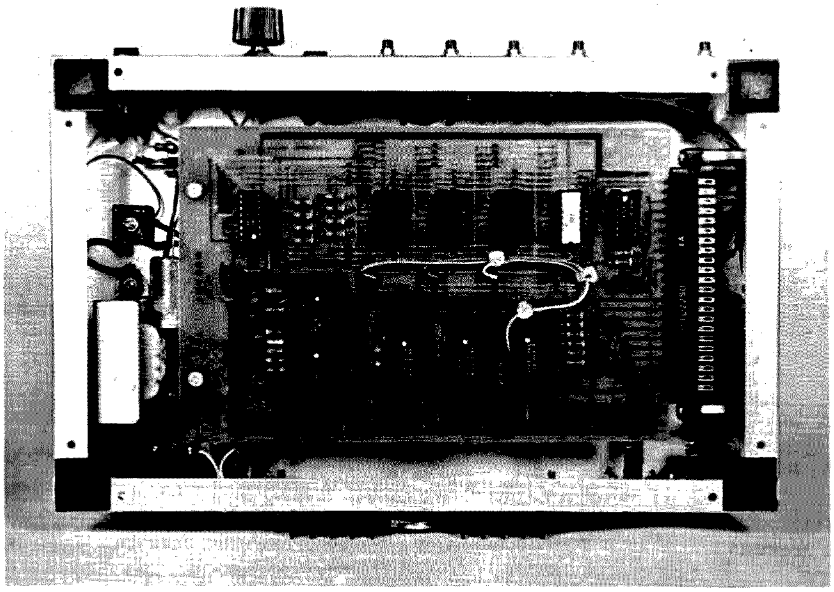
Alternatives

If the reader was not satisfied with using the PROMs selected in this article, there are a number of PROMs available from which the reader could choose. Texas Instruments, for example, offers the 74186 (512-bit, 64 words by 8 bits), 74187 (1024-bit, 256 words by 4 bits) and the 74188A (256-bit, 32 words by 8 bits). There are pin-compatible equivalents available from other manufacturers. The Intersil IM5600C is pin-compatible with other 256-bit PROMs including the Texas Instruments 74188A and Signetics 8223.

If the reader was reasonably sure that his program would not change, the 1024-bit PROM might be a better choice with simpler supporting logic. Additional benefits include less than 2¢/bit (compared to about 2½¢/bit for 256-bit PROMs) and one third the board area. One possible disadvantage is the eight programming cards which need to be filled out.

Pin Assignments

1 TTL input. Logical 1 (+2.5-5.25 V) will key transmitter. Ground if not used.
2 TTL input. Logical 1 (+2.5-5.25 V) will key transmitter. Ground if not used.
3 TTL input. Logical 1 (+2.5-5.25 V) will key transmitter. Ground if not used.
4 TTL input. Logical 1 (+2.5-5.25 V) will key transmitter. Ground if not used.
5 A spare
6 B spare
7 C spare
8 D spare
(5–8) May be used to externally enable the PROMs instead of U3 & U4, or connected to the chip enables to drive external LED displays.
9 Keyer output. Designed to drive transmitters utilizing negative grid-block keying. The PNP driver transistor specified will withstand −100 volts under key-up conditions. Do not use with cathode keyed transmitters.
10 Digital output. Do not use for keying transmitter. Output is low as transmitter is keyed. Logical 1, +2.5-5.25 V. Logical 0, 0 to +.4 V.
11 N.C.
12 N.C.
13 Start program A. Momentary contact closure to ground to start.
14 Start program B. Momentary contact closure to ground to start.
15 Start program C. Momentary contact closure to ground to start.
16 Start program D. Momentary contact closure to ground to start.
17 Stop program ABCD. Momentary contact closure to ground to stop.
18 To speed control.
19 To speed control.
20 Memory digital output. Do not use for keying transmitters. Output is high as transmitter is keyed. Logical 1, +2.5-5.25 V. Logical 0, 0 to +.4 V.
21 DC volts input. +4.75 V to +5.25 V.
22 Digital Ground.



This PC board is the prototype version. The revised board has two additional jumpers. The filter capacitors are mounted under the circuit board. C3 is partially visible. C5 and C6 are connected directly to U12 and are not visible.

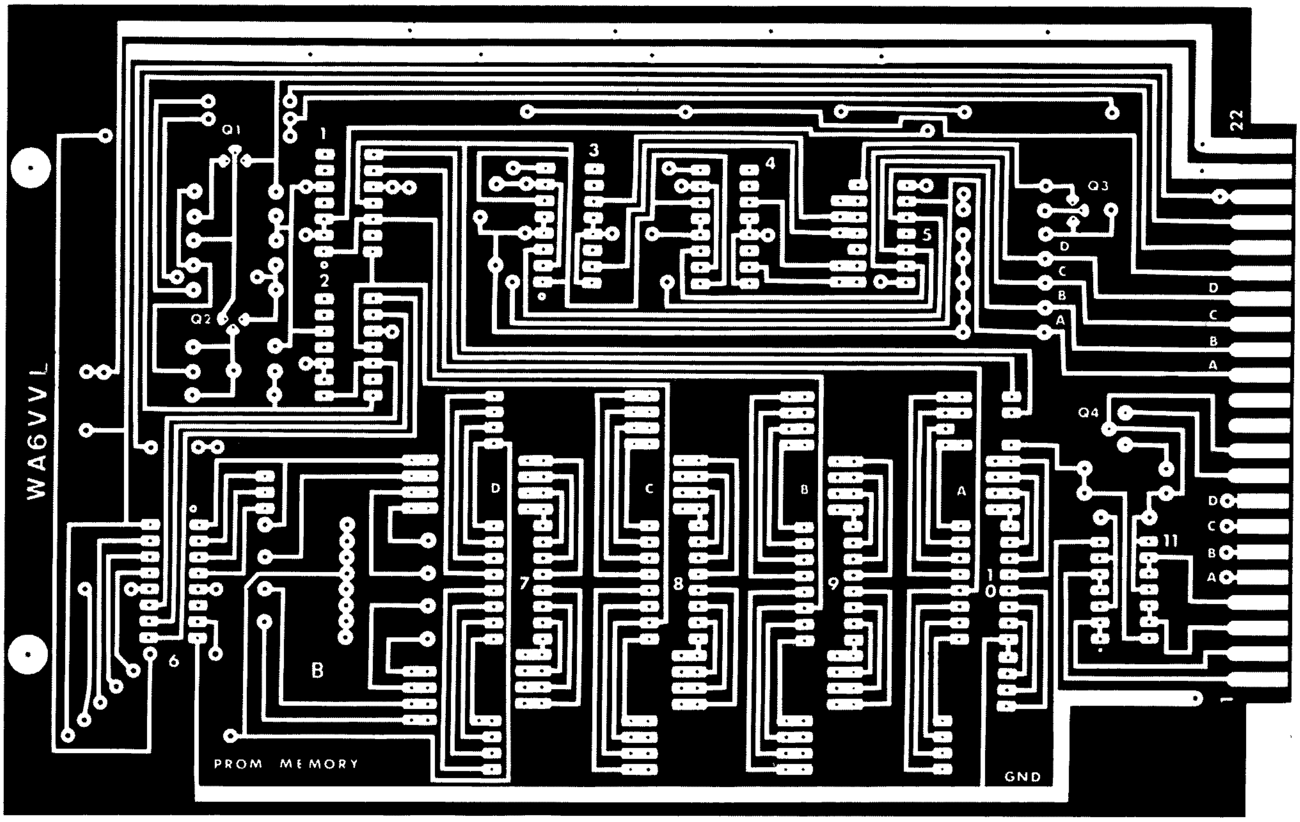


Fig. 4. PC board (full size).

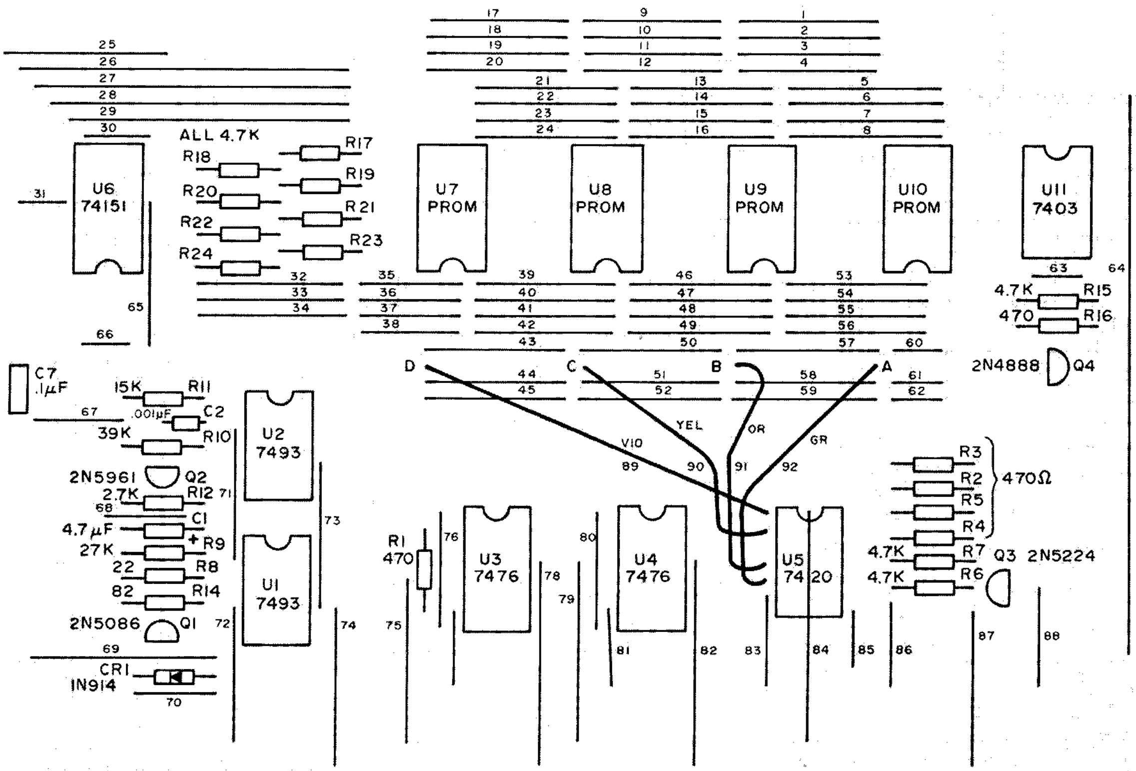

Fig. 5. Component layout.

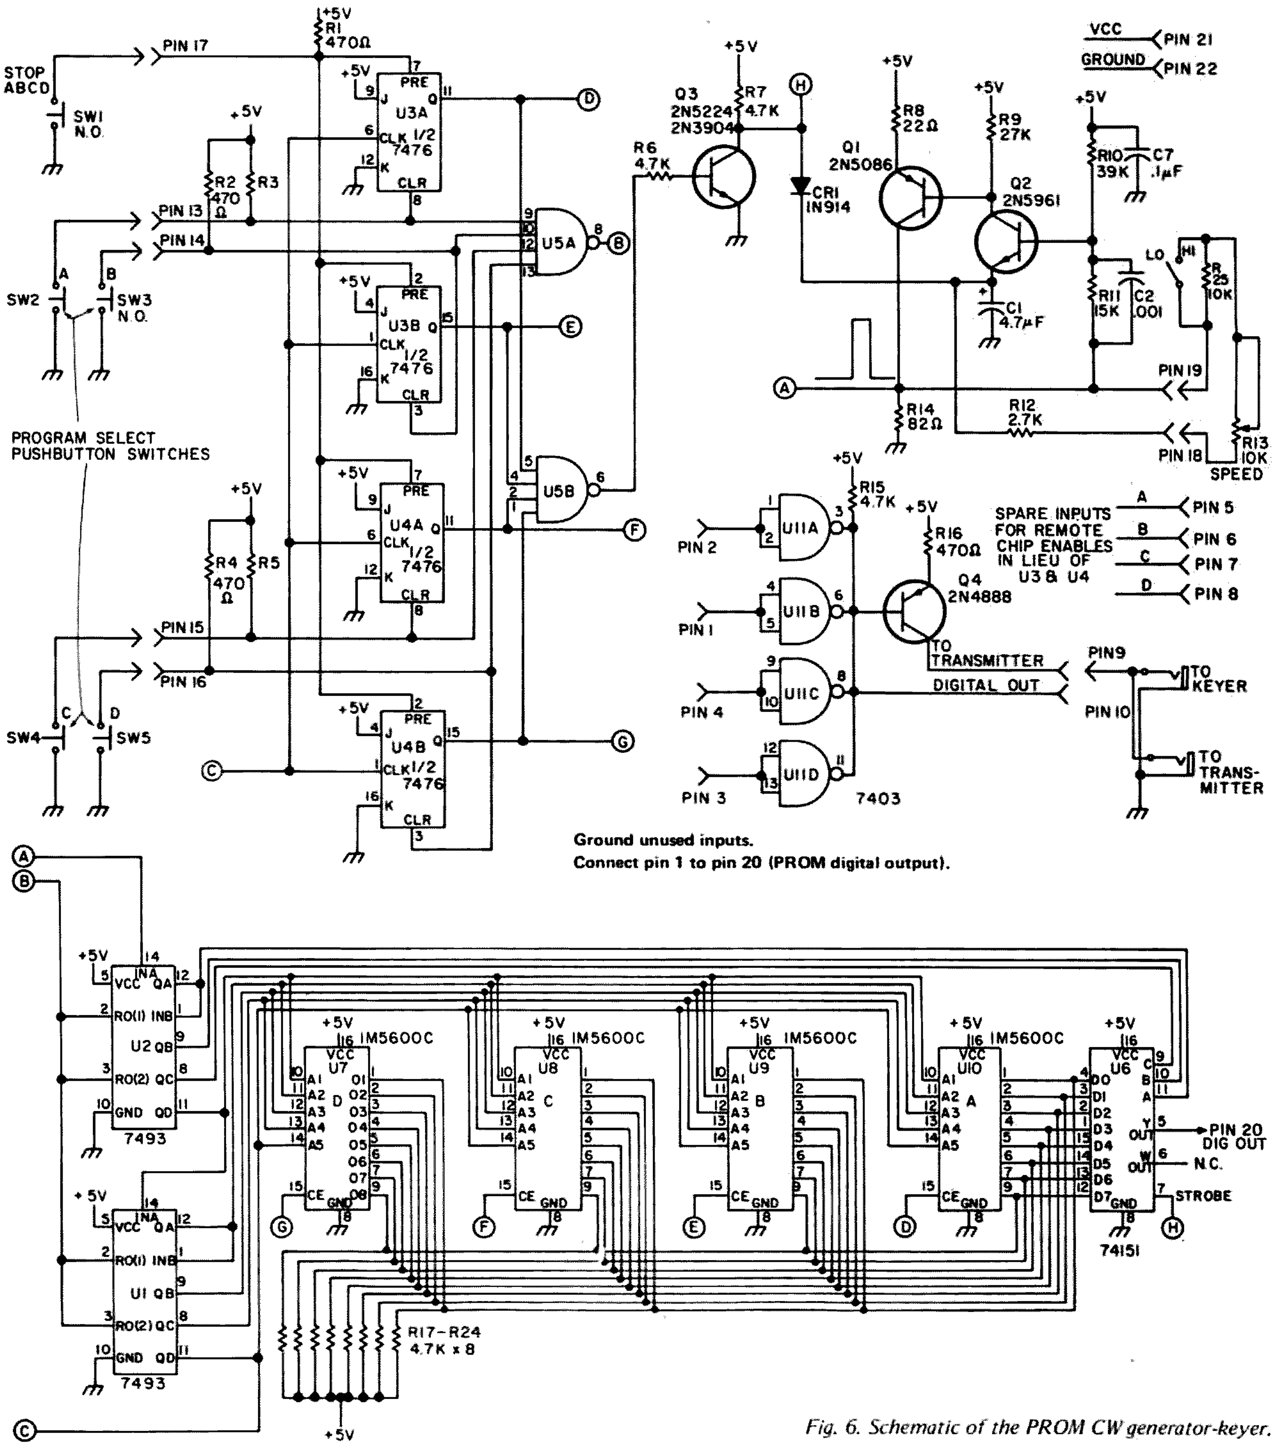

Fig. 6. Schematic of the PROM CW generator-keyer.

Conclusion

The memory described here has been designed specifically for my CW operating habits. Many variations in construction, chip enable and address circuitry, memory size (bits), and PROMs are possible.

Using my board, total construction costs should not exceed $60.00 assuming the reader had to purchase all the parts. Approximately 40% of the cost is for the PROMs.

I would like to thank Alan Burgstahler WA6AWD for providing negatives and prototype circuit boards while developing the memory. ■

AM is not Dead -- It Never Existed at All

Over the years, amateurs have used various modes of transmission. In the past, the rules and regulations specifically permitted types of modulation on certain frequencies. Unfortunately, these rules made unclear the actual facts relating to modulation. Best use of the spectrum requires that we select our modes of transmission carefully, and to do this we must understand their characteristics.

The simplest is AM. When radiotelephony was invented, it utilized amplitude modulation. This mode was erroneously believed to consist of the varying of transmitted carrier power in step with the audio. Some persons still believe that this is true.

To understand AM, one must simply understand mixers. When two signals are added together in a mixer, the two original signals appear in the output, as well as the sum and difference of the inputs. Thus, if a 1 MHz signal is mixed with a 1 kHz signal, the output consists of four frequencies: 1 MHz, 1 kHz, .999 MHz, and 1.001 MHz.

That is what happens in an AM transmitter. The carrier signal passes through the mixer, as well as the audio signal. The audio is not passed to the antenna, being far too low in frequency. But the sum and difference products do pass, and they are the sidebands that are transmitted. All intelligence is transmitted on the sidebands, and the carrier never varies.

In the receiver, the same process is applied to the composite signal. The sidebands mix with the carrier, producing audible difference frequencies. It is obvious that the carrier serves no necessary function, so it can be eliminated in transmission. The two sidebands are also identical, so one of them can be eliminated, resulting in great bandwidth reduction. The bandwidth of AM is equal to twice the highest modulating frequency. For voice, we assume 6 kHz; the bandwidth of single sideband without carrier is equal to the highest modulating frequency minus the lowest modulating frequency, in this case 2.7 kHz. This permits more stations to occupy the same band.

The carrier signal is regenerated in the receiver when suppressed carrier is used. If one transmits carrier, it will show up as an audible note on any AM signal it is near. This heterodyning caused tremendous interference when AM was the dominant mode of transmission, and plagues today's CBers. It is especially disturbing when one realizes that a majority of the transmitter's output power is being wasted on carrier. The carrier, in AM, must be greater in amplitude than the sum of the sidebands when 100% modulation is used. Besides causing QRM, the carrier serves to help the transmitter heat the shack and generate business for replacement tubes and power supplies. A "200 Watt" SSB transmitter is far lighter than a "200 Watt" AM transmitter, because of the easier duty cycle.

Frequency Modulation?

More recently, hams have taken to a mode called "frequency modulation." While AM does not actually consist of a varying carrier amplitude, FM is frequently believed to consist of a varying carrier frequency. Once again, many hams have made the same mistake. Modulation consists of the generation of sidebands, not the manipulation of a carrier wave.

How wide is FM? The bandwidth of double-sideband AM is equal to twice the maximum modulating frequency. But the bandwidth of FM — *all* useful FM — is greater than the bandwidth of the equivalent AM signal. This is because FM transmission consists of a carrier, *whose amplitude varies*, and multiple sidebands. The higher audio quality of FM, and the superior noise limiting, are due to the redundancy inherent in FM.

Let's examine an FM signal and see what makes it tick. First a couple of terms: Modulation index is the deviation of the carrier divided by the audio frequency causing this deviation. Deviation ratio is the highest deviation divided by the highest modulating frequency. The deviation ratio indicates the maximum deviation actually found.

Deviation? That's a bit tougher to explain. Deviation is the *apparent* variation in carrier frequency, extrapolated from the effect of lowering the modulating frequency towards zero. By itself, it's a far less useful term than we like to think. The carrier frequency of an FM signal does not vary! The average frequency is varied by modulation, just as the average amplitude of an AM signal is varied by modulation, by adding sidebands.

In AM, the two sidebands are in phase. Since they rise and fall together, the apparent frequency of the envelope does not

vary. In FM, the sidebands are out of phase. Either the upper or lower sidebands are more powerful at any given portion of the modulating waveform. Therefore, the average power in the signal varies in frequency.

This phase relationship has some interesting effects. Since the overall amplitude does not change, it is possible to generate as many sidebands as one might want. That means greater redundancy, and redundancy in any system makes for greater fidelity and accuracy. The carrier power is distributed among the various sidebands, and reaches zero at several values of modulation index. One can measure the deviation of a wideband signal by determining how many times the carrier dips to zero as the modulation is increased.

To determine the relative phase and strength of each sideband, one looks at a mathematical concept called a Bessel Function. Looking at the Bessel chart, one can tell which sideband is doing what, when. Each significant sideband begins to come up rapidly at a given index. One could use the chart to determine the bandwidth of an FM signal, if the modulation index and frequencies are known. An easier way is to approximate: Bandwidth equals twice the deviation plus twice the maximum modulating frequency. Don't forget that last half like the FCC did!

The phase relationship between sidebands is complex, but one feature is fairly easy to understand. The phase of the odd-numbered sidebands is different between the upper and lower sides of the carrier, while even-numbered sidebands are in phase with each other. AM signals have only one set of sidebands, the first (odd-numbered), and they are in phase. That is a crucial difference, which becomes important in phase modulation.

Phase modulation is similar to frequency modulation, but there is one major functional difference. The frequency response of FM is linear, with equal amplitude tones producing equal deviation. PM has a rising audio response, with higher frequencies generating more deviation, at a rate of 6 dB/octave. PM deviation is directly proportional to modulating frequency.

Phase modulation can be used as FM if the audio response is corrected. Communications FM, such as hams use, is actually PM in most cases, with an audio response that rises within the speech range. This is called pre-emphasis. Most FM systems use some pre-emphasis. With broadcasting, it is set to begin at about 400 Hz, and rises to about 17 dB at 15000 Hz, the high end. Even tape recorders and phonograph disks use pre-emphasis, because noise is linear with regards to frequency, and thus most of it is in the treble range. Receivers incorporate de-emphasis which restores the tonal balance while reducing the noise.

Pre-emphasis is needed with FM for another reason. Since the quality of reception is dependent upon the modulation index, and the modulation index falls as the modulating frequency rises, pre-emphasis helps keep the treble range index high enough to overcome noise and interference.

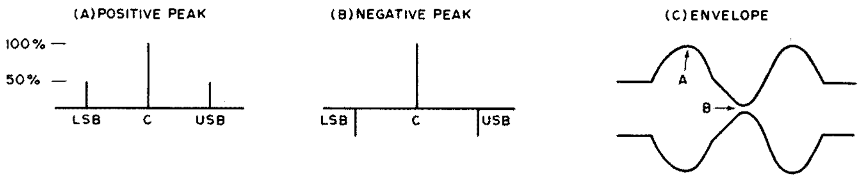

Fig. 1. AM sidebands vs. effective envelope. Direction of sideband indicates phase.

One great benefit of FM's redundancy is the capture effect. A signal will completely cover a weaker one on the same frequency once the capture ratio is attained. This works with noise too; a "full quieting" FM signal can be just 3 dB stronger than a totally unreadable one with a good detector and a deviation ratio of about 5, which is the broadcast standard. But if the deviation is reduced, the capture effect lessens. Narrowband FM such as is used on 2 meter repeaters has very little capture effect, with its deviation ratio of 1.6 or less (5 kHz deviation and 3 kHz modulation).

But phase modulation reveals how similar narrowband FM and AM really are. One can generate PM by actually shifting the phase of a carrier. One radian of shift equals a modulation index of 1, but in practice only about half that can be achieved with a phase modulator, and undistorted broadcast quality must have less shift. If we accept that a phase modulator only produces enough shift for one set of significant sidebands, we can use the Armstrong method of modulation, developed by the inventor of FM, Major Edwin Armstrong.

Armstrong knew that PM and AM differed mainly in phase relationship, so he generated a double sideband signal in a balanced modulator, shifted it ninety degrees, and reinstated the carrier. The result, provided the carrier was strong enough, was PM. This system has been used in broadcast transmitters, but the amount of frequency (and hence, deviation) multiplication needed is very great. For wideband use, direct FM is easier. Note that there is no pretense of shifting the carrier frequency with the Armstrong method. What slight amplitude modulation results is quickly lost in the Class C multipliers needed. Try feeding AM into Class C multipliers, but not with an antenna!

FM Reception

The simplest way to receive AM is with a diode demodulator. The best way is with a synchronous detector, which takes advantage of the redundancy of the two sidebands, but that practice is not yet common. Diode detectors don't work with FM, since the sidebands all cancel each other's amplitude variations and beat frequencies. Thus, to detect FM, a different system was invented. The most common is the discriminator.

The discriminator compares the amount of signal above the center frequency with the amount below the center frequency. The resultant voltage reflects the modulation. Whether there are sidebands or a swinging carrier does not matter here. The ratio detector is a variant of the discriminator that automatically cancels amplitude variations, such as AM and noise. Both forms are common.

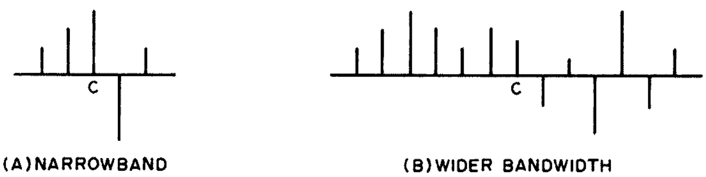

Fig. 2. Narrowband vs. wideband FM.

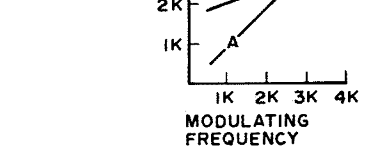

Fig. 3. Modulation frequency vs. deviation. (a) Phase modulation. (b) Direct FM. (c) Compromise pre-emphasis.

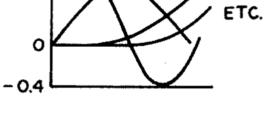

Fig. 4. Bessel function showing amplitude and phase of various sidebands.

One newer way is to use a phase locked loop. The PLL is a necessary part of an AM synchronous detector, where its advantages are drastic over the older diode system. With FM, the PLL detector attempts to lock an oscillator onto the frequency of the input, which appears to vary as the average of the sidebands swings back and forth (it acts almost as if there really were a swinging carrier). The important advantage is that a PLL need not receive the entire FM signal, but only the first two sidebands on each side. It will then have enough to lock onto. By receiving a wideband signal as if it were narrowband, the receiver can slice out noise and interference among the outer sidebands, at the expense of wideband's quieting. A PLL detector also inherently tracks drift with less distortion than a discriminator, without an automatic frequency control circuit.

So What's CW?

We have already seen that the carrier does not vary in amplitude when we transmit AM, and that the carrier does not vary in frequency when we use FM. Let's apply our understanding of AM type A3 telephony to type A1 telegraphy — good old CW.

CW is a form of AM, and thus has a bandwidth and sidebands. The sidebands are generated by the keying, since a change in effective amplitude necessarily causes sidebands. The bandwidth of a CW transmitter is determined by the key click filter. If the transmitter's rise time is short (sharp keying), there may be clicks, which are wider sidebands than necessary. If the rise time is made very long, the dits will get mushed with fast code. Contrary to common belief, keying speed does not affect bandwidth. Potential keying speed does, and a Novice probably shouldn't use as little keying filtration as a fast brass-pounder.

Now for the clincher: Since CW is a form of AM (modulated by squared waves, so to speak), it follows that keying (modulation) should not affect the carrier. Here's a logical sequence, all of which is true in its own way:

1. In conventional full-carrier AM, the amplitude of the carrier is not affected by modulation. Sidebands are generated which carry the information; the composite amplitude of the carrier plus sidebands varies by the addition and subtraction of carrier and sidebands.

2. Assume series-gate AM transmission (grid modulation). When the modulating waveform is at its most negative, the modulated grid reaches the point of zero tube output. At its most positive, the tube reaches maximum output. This system produces a carrier and sidebands as per above.

3. Assume a square wave is fed into the modulated stage. During one half the cycle, the tube is entirely cut off; during the other half, the tube conducts completely. The ironclad rule of AM — carrier unmodulated by sidebands — still stands; the high harmonic content of the square wave produces broad sidebands. Softening the waveform by the addition of a low-pass filter to the modulation reduces the width of the sidebands.

4. Replace this square wave with a telegraph signal. There are still sidebands and an unaffected carrier, even though the tube is cut off during part of the waveform. This is common grid-block keying CW. Even with the key up, the carrier is still there!

Now you know as well as I do that when a key is lifted, the carrier goes away, right? But put in a *narrow* CW filter, say 40 Hz, and key rapidly. It will be noticed that the keying is softened if not obliterated by the "ring" in the filter. This ring can be reduced by proper filter design, but a certain amount is inherent in any given bandwidth, because the higher order sidebands are being cut off by the filters! If one were, theoretically, to narrow the bandwidth to a fraction of a Hz, the signal would ring for several seconds. Narrow the filter infinitely, and the carrier remains infinitely present. The sidebands are close to, and out of phase with, the carrier.

In case you're thoroughly confused, just remember that a carrier wave is really only a mathematical concept, and like most mathematical concepts, carries very little intelligence to most of us! ■

Is Extraterrestrial Communication Possible?

For all we know, CQs may be coming our way, unbeknown to us, by sophisticated communication techniques beyond our comprehension, just as the New Guinea natives who communicate with drums are unaware of the international radio traffic passing over their heads . . .

Throughout human history the art of long-distance communication by audible, visual, or electromagnetic methods has played an important role in advancing the culture of the human race. When Homo erectus emerged from the mists of antiquity a couple of million years ago, his upright position freed his hands for the delicate manipulation of tools and led to the development of a larynx and speech box that set him apart from all other animals. One can imagine early man communicating over distances with his brethren by means of strident calls, and his successor, Homo sapiens, by means of fire or smoke signals, drum beatings, sunlight flashes from shiny objects, and other primitive methods.

It was not until a century ago that man's effort to overcome great distances by rapid communication succeeded with the advent of telegraphy. In that same century a few adventuresome dreamers had already set their sights much farther out. Among the elaborate schemes that had been concocted to signal our presence to other worlds in the solar system were the following: the planting of a ten-mile-wide strip of pine trees in Siberia in the form of a right triangle; a twenty-mile circular ditch filled with water over which kerosene would be poured and set afire; a powerful concave mirror that would focus sunlight on Mars and burn simple numbers in the desert sands of that planet; a network of large sunlight-reflecting mirrors stategically positioned in several European cities to conform to the configuration of the Big Dipper in the constellation Ursa Major as a sign of intelligence on earth.

In 1899 the eccentric electrical pioneer, Nikola Tesla, undertook to transmit a powerful electrical signal into space from his Colorado laboratory and to detect any possible replies. He employed a large primary coil 75 feet in diameter and a 3 foot copper ball mounted on top of a 200 foot tower. He figured that powerful alternating surges of electricity introduced into the copper ball and into the ground would interact with the earth's magnetic field to increase the power of the radiated signal. Although there were no extraterrestrial responses to his efforts at the time, it was reported that incandescent lights were set glowing 26 miles away. A year later he claimed to have picked up interplanetary signals.

In 1921 Guglielmo Marconi believed he had detected regular pulsed signals from outer space in the high meter band while conducting atmospheric tests aboard his experimental yacht, the Elettra. In 1924, when Mars was closest to the earth (35 million miles), the astronomer David Todd arranged to have the U.S. government's high-powered transmitters turned off every five minutes before the hour between August 21 and August 23. During these five minute silent intervals he used a special receiver tuned between 50 and 60 kHz to record on tape any signals coming through. Out of a hodgepodge of dots, dashes and jumbled code groups, which he and listeners throughout the country heard, nothing definite could be ascribed to an outside source. Today we know that such very low outer-space frequencies are reflected back into space by the ionosphere.

Throughout the following quarter century interest in extraterrestrial communication more or less lapsed until the growth of radio astronomy after World War II. As radio telescopes grew in size and observing techniques improved, the time seemed opportune to speculate once more on the feasibility of detecting extrasolar signals from intelligent sources in space. In a September 19, 1959 issue of the prestigious British scientific journal *Nature,* physicists Giuseppe Cocconi and Philip Morrison

presented logical reasons for instituting a search to detect artificial signals in outer space with large radio telescopes. They concluded that the probability of finding any was difficult to estimate, but if we never search, the chance of success is zero.

In 1960 the first modern attempt to look for artificial signals in space was conducted by Frank Drake at the National Radio Astronomy Observatory in Green Bank, West Virginia. This was the famous *Project Ozma* named after the legendary princess in the imaginary land of Oz. The 85 foot radio dish was pointed, when time permitted, in the direction of two relatively close solar-type stars, Tau Ceti and Epsilon Eridani, about eleven light-years distant. After 150 hours of unrewarded observing from May through July, the search was abandoned.

In 1967 there was a brief flurry of excitement when the first pulsar was discovered. Perhaps "little green men" were trying to contact us with their very precisely-timed pulsed radio signals. We have since found over one hundred pulsars in different parts of the sky flashing radio pulses up to thirty times per second. They are the natural consequence of certain stars that have gravitationally collapsed after exhaustion of their available nuclear fuels into small, rapidly-spinning, highly-condensed objects emitting beamed radio pulses which the earth intercepts.

In the ensuing years there have been a few sporadic attempts undertaken to detect artificial signals in outer space, particularly since 1972. So far several American and Canadian radio astronomers have been unable to locate anything resembling intelligent coded signals from a number of nearby sunlike stars. Neither have attempts by two groups of Soviet astronomers, seeking pulsed intelligent signals over the entire sky from any source, been successful to date. The most unusual search in progress is that conducted with the Arecibo 1000 foot radio telescope in Puerto Rico. Here several nearby galaxies with their billions of stars are being monitored intermittently on several microwave channels. There are presently too many other immediate and rewarding uses of radio telescopes than to spend time looking for coded extrasolar signals with little hope for success.

It would seem that 1420 MHz is a logical search frequency of universal significance. It is the emission frequency of the dark, neutral hydrogen clouds that outline the spiral arms of our galaxy. This frequency happens to lie in the quietest terrestrial portion of the microwave spectrum between 3 and 30 centimeters where the effects of atmospheric absorption and cosmic background noise are at a minimum. If other galactic inhabitants are also surveying the hydrogen distribution in the galaxy, their receivers and ours, tuned to the same spectral region, might offer the best chance of the successful receipt of coded transmissions around the hydrogen-emitting frequency. However, it is conceivable that an advanced galactic society, desiring to leave this channel open for exploration of the galactic structure just as we do, will not beam CQs on or near this frequency. A more suitable communication frequency might be the microwave region between the emission lines of hydrogen (H) at 1420 MHz and hydroxyl (OH) at 1668 MHz observed in the interstellar clouds of our galaxy. This microwave section has been called the *water hole* because H and OH are the dissociation products of water (H_2O). If water-based life is prevalent elsewhere, it might be natural for advanced societies to employ a precise frequency related to the center of mass of the water molecule. This communication frequency lies at 1652.42 MHz.

We must remind ourselves that we are tyros in the communication enterprise. For us, passive listening is presently far more advantageous than active beaming which requires enormous expenditures of energy. Obviously, if there are no civilizations with the will to transmit as well as to receive out of the hundreds of thousands that presumably exist in our galaxy of several hundred billion stars, interstellar communication will never materialize. For all we know, CQs may be coming our way unbeknown to us by sophisticated communication techniques beyond our comprehension, just as the New Guinea natives who communicate with drums are unaware of the international radio traffic passing over their heads. The acquisition of a message obviously is the most difficult part in establishing an interstellar dialogue. Once acknowledged and replied to, assuming we can decipher it, arrangements can be made with respect to channels of operation, power requirements, and communication modes for the proper exchange of knowledge between two galactic cultures, even if this takes centuries.

Project Cyclops **involves an array of some one thousand 100 meter dishes spread out over a circular area ten miles wide at a cost of 10 billion dollars, about one-third the cost of the manned missions from Mercury to Skylab. The installation would be capable of intercepting coded beacon signals from civilizations out to 1,000 light-years . . .**

Our first active attempt to beam a message to a distant stellar outpost was made in November, 1974. The newly-resurfaced 1000 foot radio dish at Arecibo, Puerto Rico focused a 450 kilowatt, binary-coded, beamed signal in the direction of the great globular star cluster in Hercules. Even though its distance is 24,000 light-years, this object was chosen because the beam width of the arriving signal 24,000 years from now would just span the diameter of the cluster, thus wasting no power; secondly, there might be a sufficient number of civilizations out of the million stars in the cluster capable of intercepting the "astrogram." The binary-coded message contained information about the earth's biology pertaining to the composition and structure of the DNA molecule, the human population, an inventory of the solar system, and a schematic of the radio telescope that beamed the coded signal.

Lastly, there remains for discussion the most grandiose project of all: the Cyclops system of communication proposed by Dr. B. Oliver, a vice president of the Hewlett-Packard Company. *Project Cyclops* involves an array of some one thousand 100 meter dishes spread out over a circular area ten miles wide at a cost of 10 billion dollars, about one-third the cost of the manned missions from Mercury to Skylab. The installation would be capable of intercepting coded beacon signals from civilizations out to 1,000 light-years, or eavesdropping on the radio leakage from local transmissions broadcast by communicating societies up to distances of 100 light-years. The array could also be used to radiate directional signals with extremely narrow beam

lobes. A large fraction of its time would, in addition, be devoted to investigations of natural radio sources on the sky. It is estimated that within 1,000 light-years there are some 1.7 million suitable stars. By "suitable" we mean solar-type stars which possess sufficiently long life spans to permit the slow, orderly biological planetary evolution of an intelligent species. For example, our sun is about 4.5 billion years old and biological evolution on earth required about 3.3 billion years to produce modern man. Under the optimum conditions wherein interstellar beacons operate continuously and we can monitor all likely channels simultaneously in the microwave region with a receiver having at least one billion outputs, the search could be completed in about 30 years. Otherwise we should be prepared to spend centuries of effort in a project with some chance of success in the distant future.

In the meantime, there remains the slim prospect of serendipitous contact. We might accidentally stumble onto artificial signals being randomly directed our way, intercept signals being exchanged between two other worlds, locate signals between a cruising spaceship and its parent planet, detect signals from an automated probe monitoring our solar system and reporting to its home station or mimicking our communication to gain recognition (an unlikely source of long-delayed echoes), or eavesdrop on a galactic network exchanging information among its member societies. Once interstellar communication is initiated, it will mark the end of our cultural isolation and establish our entry into the galactic club of civilized societies. ■

MORE DEPARTMENT OF COMMERCE STUFF

Last month I told you about my official headquarters being changed from Washington to Philadelphia. It was much better than traveling out of Washington for 30 to 40 days without seeing my family. So, as I told you, the first thing I did after receiving the assignment was to move my wife and Wayne to Philadelphia.

In those days there were only three classes of pilot licenses: Transport, Limited Commercial and Private, each with its limitations. All required a written examination and a flight test. It was up to the applicant to furnish the airplane for his flight test. If the flight test was in a dual control ship, I'd ride with him to see how much he slipped and skidded on his turns, figure 8s, 180s and 360s – in other words, to see whether he was flying the ship or the ship was flying him. Also, I very seldom licensed an airplane without test flying it myself. I had three inspectors assigned to my region, so the first thing I did was make up a schedule of dates and places where one of us would be available to inspect aircraft and to examine and test for pilot and mechanic licenses. This was sent to all the active airports in the region and to all applicants.

On one of my trips to the Richmond Flying Field I had an application for a license for Roscoe Turner's "Flying Cigar Store" ship. If I remember correctly, it was a large single engine biplane that, I believe, was an early Igor Sikorsky stick and wire job. It was very well built and, according to Roscoe, was very nice to fly. It had to be good since the runway he operated out of, across the field from the Pitcairn hangar, was only about 30 feet wide and had deep ditches on each side. At that time Roscoe had a pet crow that he took everywhere with him. The crow had a habit of picking up anything that was shiny such as a wrench, pliers, etc., and hiding it. What fun. As you may possibly remember, Roscoe was always dressed in smart uniforms. I asked him where he got them and he said that his wife designed and had them made for him. Anyway, uniform or not, Roscoe was an excellent pilot.

In late 1927 and early 1928 I spent quite a little time based at Langley Field, Virginia. I was stationed there in 1925, so I still had a lot of friends there. They put me up in the B.O.Q. (Bachelor Officers' Quarters) and, for a very nominal fee, fed me at their mess. The NACA (National Advisory Committee for Aeronautics) very kindly hangared my plane. Quite a few of the pilot personnel at Langley and at the Naval Air Base at Norfolk wanted to qualify for civilian pilot licenses, so I processed their applications. Also, some of the "Non Coms" and Specialists qualified for airplane or engine mechanics licenses. The NACA had quite a stable of planes in their hangar, some of which they were nice enough to let me fly. For my money, their Fokker D7 was the best handling ship of the lot. Tom Carrol, an old friend of mine, was chief test pilot for the NACA at that time.

On the morning of the 15th of November 1928, I answered the phone at my office at the Philadelphia Airport and heard someone say, "This is the White House Vacuum Cleaner Department" (Hoover was then the Secretary of Commerce). I knew right away that it was Ralph Lockwood, the Supervising Inspector in Washington and my boss. I asked him why he was wasting the taxpayer's money on long distance phone calls. He said they had a problem and needed my help. He said, "You know that nice new Stearman we have in our Bolling Field hangar?" I said, "Yes." "Well," he said, "Clarence Young (Chief Air Regulation Division, and Lockwood's boss) is going to make a tour of Europe next month and wants to take the Stearman along. However, in order to do this, the ship needs some additional instruments and a radio installation that can only be done at the Stearman factory in Wichita. So Clarence wants you to ferry it out and back." I told him that it would be sort of difficult for me to get away just then as we had just raised the price of an untested pilot license to $100 and the price of covering up a dry rotted longeron to $150, and we were busy running to the bank. His answer was for me to throw a couple of shirts in my flight bag and fly down to Washington that afternoon. They would have the Stearman on the line, all gassed, warmed up and ready to go first thing in the morning. Well, an order is an order – so I complied.

Instrumentation in most civil aircraft in those days was pretty sketchy. Many were equipped with only a compass, altimeter and air speed indicator, some with a turn and bank indicator. This was about the story for flying and navigating instruments. The Stearman had all these for the outbound trip plus a rate of climb indicator and radio on the return trip. An 1100 to 1200 mile cross-country trip, especially if it was not over established airways, was a bit more complicated in 1928 than it is now. To be sure, there were airway strip maps to be had, but once you were off those, the Rand McNally state maps were about the only maps available. So you drew your flight line on the state maps and tried to follow it. Following railroads in mountainous country was not recommended as they sometimes went into tunnels without warning. A combination of visual and compass navigation was what I generally used.

The trip out was normal for late November – high head winds, snow, sleet, etc. I had to make an unscheduled landing and overnight at Terre Haute because the ground was getting a little too close. There were a lot of heavily flooded areas between Anglum and Kansas City, and snow from there to Wichita. Upon my arrival, I phoned Stearman and told him I had arrived with the package he had been expecting from Clarence Young. He said he'd send a pilot to take the ship over to his postage stamp sized factory landing place. It took them four days to do the work on the ship. Then, while I was testing it, prior to returning to Washington, the lever controlling the horizontal stabilizer let go and put me into a dive I couldn't control with the elevators. I lost about 800 or 900 feet before I realized what had happened and I corrected it just in time. All I had to do was to pull the stabilizer control lever up and hold it with my left hand while I operated the control stick and throttle with my knees and right hand to come in for a landing. It didn't take Stearman more than a couple of hours to make the necessary repairs, so I was on my way by noon.

I got back to Washington the afternoon of November 24th just in time to jump into my Travelair and make Philadelphia before dark. ■

5/8 Wave Power for Your HT

The majority of the commercially made two meter FM hand-held transceivers today have 1 or 2 Watts output into quarter wave antennas or rubber ducks. There are many times when an FM operator would like to have a little more gain to work out better from poor locations. This article describes a tunable 5/8 wave telescopic antenna to use with a rig such as the Drake TR-22 transceiver.

The antenna design is not a new one. However, the adaptation for use with portable equipment and base stations is novel. It basically consists of four parts: (1) a 44" or 45" telescopic transistor radio replacement antenna rod; (2) acrylic 1/2" OD, 1/4" ID, 2-1/2" long plastic insulator; (3) a 4 turn coil and an NPO 3-12 pF ceramic trimmer; (4) PL-259 coaxial connector. Use with the TR-22 transceiver requires an additional 90° elbow, a barrel connector and a double male connector.

Construction of the antenna is a little unusual, but can be done easily in about an hour. First, with the 2-1/2" acrylic rod, drill a 5/16" hole, 1-1/2" into the center of the rod tube. The metal telescopic rod will fit into this later. Next, prepare a 1" by 1/4" wooden dowel rod. Drill a small hole through the end of the dowel to pass a center conductor wire. Glue the wooden dowel into the bottom of the plastic insulator tube and drill a small angular hole through the side of the plastic rod to coincide with center hole of the dowel. Solder a 3" piece of center conductor from RG-58 coax to a PL-259 coaxial connector. Fish the loose end of wire up through the wooden dowel and out the side of the plastic insulator. Next, fill in the PL-259 connector with epoxy and set the wooden dowel into the connector. Be sure to pull the center conductor wire as you work the dowel into the epoxy. Let epoxy set up until hardened. Next, wind a coil using #12 copper wire (1/2" ID, 4 turns). Bend the ends of the coil and leave plenty of excess wire to make the hookup. Position the coil over the plastic insulator and slide it down until the first turn reaches the PL-259. File off the chrome plating from a spot on PL-259 and solder the bottom end of the coil. Solder to the coil the center conductor wire coming through the side of the plastic insulator, at 1 turn from the grounded end.

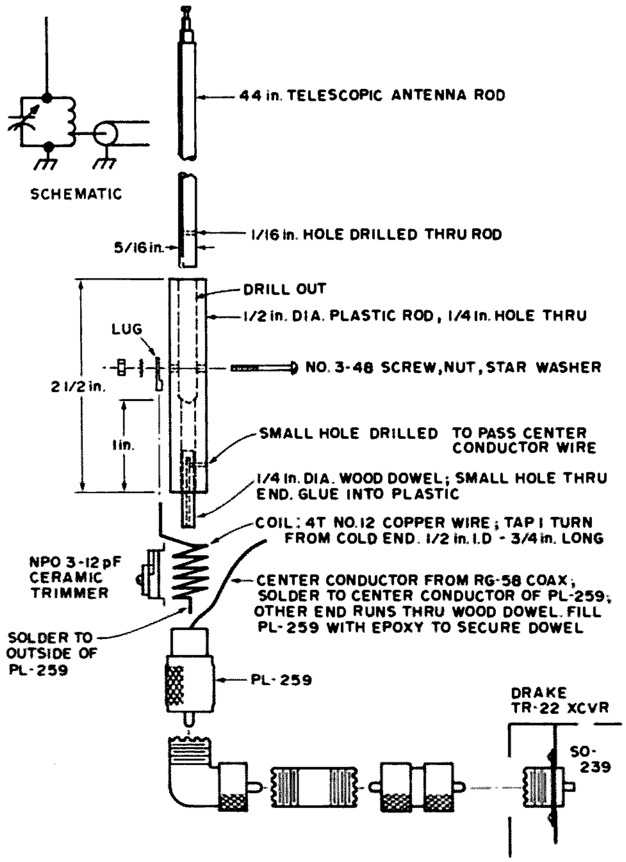

Fig. 1.

Insert the 44" telescopic antenna rod into the top of the insulator. Drill a 1/16" hole through the insulator and antenna rod. Secure with a #3-48 screw, nut, star washer and lug. Solder the

top end of the coil to the lug and tighten it down. Finally, solder an NPO 3-12 pF ceramic trimmer between the top and bottom of the entire coil. Extend the antenna rod to full length and check for rigidity. This completes the construction.

With a Drake TR-22, an additional 90° elbow coaxial connector, a barrel connector, and a double male connector must be used to adapt the antenna to the TR-22 coaxial S0-239 output connector at the rear of the unit.

Tune-up procedure is very simple; there are two ways. First, using a field strength meter in close proximity, key the transmitter and adjust the NPO capacitor with an insulated tuning wand for maximum meter indication. Or, while listening to a weak signal, adjust the NPO capacitor for maximum S-meter indication. Both methods are with the antenna in place and the rod fully extended.

The antennas constructed thus far have been very effective, with increased receive and transmit gain over the built-in quarter wave type antennas. Many repeaters in excess of 35 miles have been worked using this antenna and a 1 Watt rig. It is very useful in the home and shop, and at picnic outings and other portable locations. It is a fun little antenna to build and can be used not only for hand-helds but also for Regency HR-2 type rigs, too. Those who have the problem of no antenna allowed outside can use this antenna and have many surprising results, especially from the second floor of a structure. In most cases it will mount on the S0-239 at the rear of the rig. Be sure to re-tweak the NPO capacitor when changing rigs for optimum performance! ■

Gone in a flash... -STROBING- ...Only to return

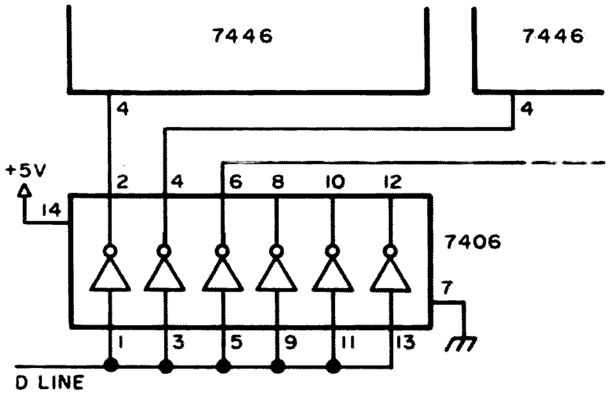

Fig. 1.

Having just recently read an article by WB4DCV in the Nov/Dec 1975 issue of *73 Magazine*, and another by WB2DFA in the Jan 1976 issue of *Ham Radio*, I thought it might be timely to write up some of the ideas used around here for strobing and general control of displays. If I didn't strobe or timeshare some of them, I could not afford my light bill each month.

While this is not a construction article, it might help some of your present or future projects. Since nearly all digital projects do their "thinking" in a binary or BCD code, a transition usually occurs somewhere in an IC (or ICs) that converts this code to the required seven-segment code and the readout numbers we understand. Further, this generally occurs in a 7446, 7447, 7448, etc., family IC or CMOS equivalent. These little multipin "black boxes" more often than not have a group of gates that seem to get overlooked quite often. Blanking, strobing, etc., are the very reasons these gates were built into the IC, so it is a shame to overlook them at the expense to our pocketbooks!

There are two pins on most of these ICs, referred to as the ripple blanking output (RBO) and the blanking or ripple blanking input (RBI) lines. Hooked together properly, these pins can be used to blank out what are called the leading zero figures on a display, or the zero(s) preceding the actual number desired (i.e., the *00*123 in the number 123). Another example: In a 5 digit counter like the K2OAW counter that I wrote up some additions for earlier (*73 Magazine*, June, 1973), a very worthwhile further addition can be realized by using these RBO/RBI lines wired properly for the leading edge zero blanking. By tying pin 5 of the most significant digit (left figure as viewed by user) IC SN7446 to ground, then tying pin 4 of the same IC to the next lesser significant figure IC SN7446 pin 5, and carrying pin 4 of one IC to pin 5 of the next IC to the right, on down until only the right-hand pair of digits (their 7446s) are not modified, you will blank all zero figures to the left of the right-hand pair. Examples: 00001 will read 01, 00011 will read 11, 00111 will read 111, 01111 will read 1111, and 11111 will read 11111. If 10001 is the number, then 10001 will read out. Only insignificant zero figures are deleted and blanked. Leave at least two right-hand digits unaffected in order to tell that the counter is indeed running and working.

Also, in a switched range counter such as the K2OAW model, always begin by counting in the upper range. This avoids the obvious errors that could occur using the zero-blanked version (i.e., 1,140,003 Hz on lower range reads as 03 Hz). I doubt anyone looking in a place for 1 MHz signals would buy the 03 Hz answer, but, done in high range first, he can't go wrong, getting first a 1140 (zero of 01140 blanked) answer, to which he adds the 03 for a 1,140,003 correct answer.

The blanking arrangement is easily defeated by a switch (if so desired) for high frequency measurements over, in this case, the low range limit of 99,999 Hz. Especially in audio measurements in most model counters, it is much easier to read 420 Hz or 1200 Hz, etc., than 00420 or 01200.

To get back to strobing, these same blanking lines can be controlled by ripple through counting devices as in the WB4DCV article (a 7490 to 7441 pair), and the blanking lines will perform the "strobe" function by sequentially blanking or unblanking a readout tied to that particular IC. Since the

exact seven-segment decoder used may require the opposite polarity than that provided by the 7441, the outputs from the 7441 may be tied to the inputs of hex inverter ICs to reverse the "sense" of the outputs (two ICs being required, with two gates or inverters left over). Just remember, to get true strobing where only one number is on at a time, make sure your outputs (from 7441 or inverters) cause all numbers to be off except the one to which the counter (7490) has driven the 7441. Note the following example.

It is further recommended that, on a 5 digit counter like the K2OAW model, the blanking lines be tied to all the decoder even or odd number outputs (or their inverted not-lines for some seven-segment decoders) of the 7441 decoder. This allows the following sequence in an all-tied-to-odd-lines version (7441 positions): (0) no lights on – NLO; (1) one light readout) on – OLO; (2) NLO; (3) OLO; (4) NLO; (5) OLO; (6) NLO; (7) OLO; (8) NLO; (9) OLO – and you have strobed 5 digits (count all OLO positions). Between digits, there is no power drawn, and, in 5 positions of the decoder 7441, only one readout is lit. If you are modifying a present counter, just leave the power supply for the lamps alone after the modification – it will just run cool for long life. If designing a new project, take the reciprocal (1/x) of x number of readouts used, times the current per readout (7 times the per segment figure in a seven-segment device), times two. The times two is a safety feature that should appear as a 1.5 to 2.0 figure in all of your power supply designs, unless you like the smell of smoke (transformers, resistors, etc.).

A recent development of my own may also be of interest. By simply tying the D line output of one of your crystal timebase dividers whose frequency is 100 to 1000 Hz to all inputs of a hex inverter IC (I used a 7406), and tying one each of the outputs to one of the blanking lines of the 7446s, an alternate means of strobing occurs that gives you an 80% reduction in power required. This may be adequate in some applications, and certainly requires the minimum of hardware. In this case all readouts are off 80% of the time, and on 20% of the time, but at a rate faster than you can follow with the human eye, so they appear to be always on (see Fig. 1).

Now some comments on counters in general, and specifically the K2OAW model I have. Mine has been in constant use since I built it over three years ago. One of the modifications I suggested in my original article was (as Peter Stark K2OAW pointed out) contrary to good TTL practice, but the entire counter has worked perfectly as described for over three years now. I have, since writing my article, made some of the modifications to my counter that have appeared in subsequent articles by Pete and others. One of these is the input circuit change by Pete himself in the Nov 1974 *73 Magazine*. This, coupled with the change from a 40673 FET to a 3N200 FET, greatly improved the input sensitivity. If I had it to do all over again, I would make this input circuit a plug-in module of some sort, since I am now building the WB2DFA *Ham Radio* input buffer circuit for comparison. Either way, I will use the input metering circuit of that article, as a little metering would sure be reassuring at times.

I had some months ago changed the first 7473-7490 combination in the counter chain over to a 74196 as in the WB2DFA circuit, and it did indeed count to 63 MHz on mine, using a discrete buffer after the 3N200 to shape the waveform for TTL (instead of the 7413) and a 74S00 for the input selector IC. I have since tried the 74S196 for the 74196 (pin for pin OK), and using the same 74S00 I can count to just over 100 MHz. I have determined that the 74S00 is the limiting factor, and, if you try the same idea, the results may vary from 80 to 120 MHz depending on your choice of 74S00 and 74S196.

I have not laid this out as a construction article, but for those of you who want to see my 3N200 arrangement, etc., on paper, please send an SASE and I'll copy up a sheet or two with all the collective information on it. It's all there for you to dig out of the articles mentioned if you have them.

In a short article like this, a pin-by-pin type of description is impossible, but the above articles and their schematics should straighten out any questions or problems on what I have described. By all means strobe, but don't make a hard job of it when it need not be! ■

By all means strobe, but don't make a hard job of it when you need not!

NEW PRODUCTS

TRICKS WITH ANTENNAS

In our September, 1975 issue, under *New Products*, there appeared a description of a coaxial coupler and a remote control relay by Inline Instruments, Inc. We had installed one of each, and the results made our 2 meter operation and UHF listening much more interesting.

The coupler was inserted inline on the coaxial cable at the transceiver and the relay was clamped to the rotating pole on top of the tower. An omnidirectional vertical was added to the top of the pole and connected to one port of the relay, and the beam was connected to the other port. The existing coax carries the energizing power to the relay, so nothing else had to be added. The plug lead of the 12 volt power supply was run to the injection port of the coupler through a switch, and the antennas could then be selected (Fig. 1). By switching from the vertical to the beam at different angles of rotation, side lobe response, front-to-back ratio, and other reflections were easily noticed by direct comparison. We discovered the true characteristics of the beam.

Being by nature tinkerers, we decided to try other schemes. Our Bearcat III VHF-UHF scanner always had low gain on UHF because of the single VHF antenna common to both bands. The Inline literature showed the relay transfer time to be one millisecond, so it was felt that it should follow the step response time of the scanner. A two transistor interface switch was built up on a vectorboard and installed in the scanner.

The coupler was transferred to the scanner coax line. A UHF antenna and the relay were added to the pole. Both antennas were connected to the relay. The scanner power supply powered the transistor switch and the relay with no problems. The relay easily followed the scanner band transfer and formerly noisy UHF signals became full quieting. There was no audible noise induced by the relay/antenna switching. The life expectancy of the relay is such that even with the high rate of switching it should last for years. Most other scanners use similar crystal and band switching techniques, so the circuit shown should be usable without modification.

Time has prevented more ideas from actually being tried out, but we would like to pass on a few application hints which might suit individual requirements.

First: Repeater antennas can be switched by tone from mobiles or remote points to provide more favorable selected area communication. A timer or second tone can restore normal condition.

Second: Two antennas can be switched in a mobile to offset undesired directional conditions.

Third: Skilled UHF operators can install converters, preamps, or varactor multipliers on the tower near the antenna. Both the accessory power and the rf is supplied via the coax line. A suggested system is shown in Fig. 2. Cable losses are greatly reduced. Note: The relay shown is not a remote control type. Since power is also required at the converter, a second coupler supplies both the converter and relay power for UHF operation.

Fourth: FM communication on VHF-UHF uses mainly vertical polarization. Fixed station to fixed station operation, using simplex frequencies, can communicate over longer distances by using horizontal polarization with minimum interference from mobiles. Horizontal to horizontal and vertical to vertical QSOs can thus be carried on at the same time. A horizontal antenna can easily be added with the use of the subject devices.

It should be noted that coaxial cable is not only costly but adds wind loading and stress to a tower or pole. Maintenance will be reduced and the shack will be neater with less cables.

Installation of the coupler and relay showed no apparent attenuation, noise or change in swr over the VHF-UHF range.

More information can be obtained by writing directly to Inline Instruments, Inc., Box 473, Hooksett NH 03106.

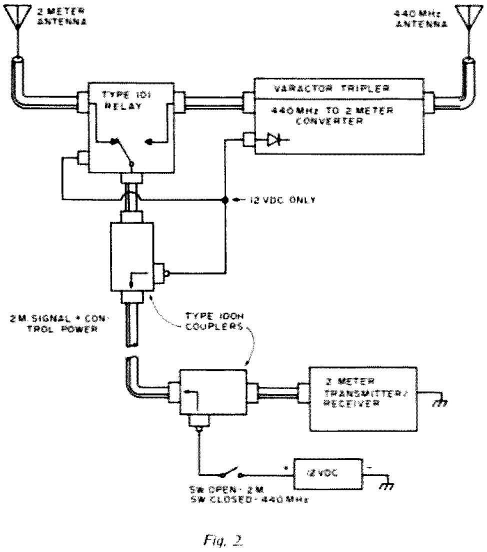

Fig. 2.

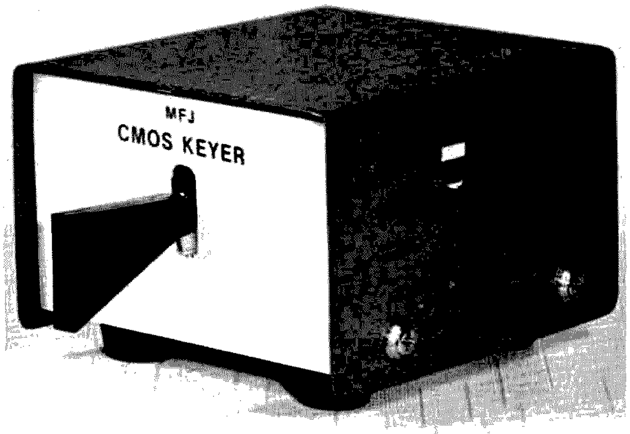
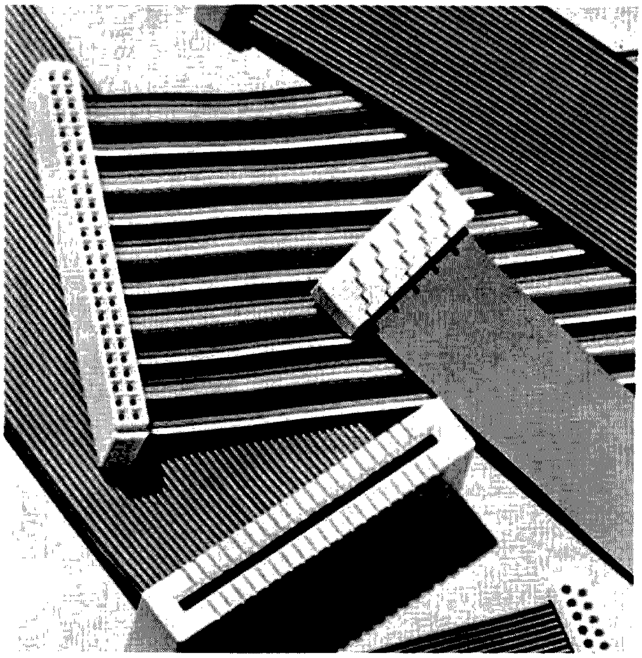


NEW MFJ CMOS-8043 ELECTRONIC KEYER

by Morgan Godwin W4WFL

Except for the omission of the model number on the lower portion of the front panel, MFJ Enterprises' new CMOS-8043 electronic keyer looks exactly like its predecessor, the CMOS-44ORS. However, appearances can be deceiving. Inside, the electronics of the CMOS-44ORS have been completely replaced by electronics based on the Curtis 8043 IC keyer chip. Thus, while retaining all of the features of the older model, the new circuitry provides the additional advantages of 1) dot memory; 2) iambic operation with external squeeze key; 3) variable weight control; and 4) reliable solid state keying for grid block and cathode keyed equipment and solid state rigs.

Completely self-contained in MFJ's standard 4 x 3-1/4 x 3-3/16 inch enclosure, the CMOS-8043 is powered by four penlight cells. The sidetone oscillator utilizes a 2N3904 which provides ample volume with the built-in speaker. Tone and volume are adjustable with internal trim pots. The unit features self-completing dots and dashes with jam-proof spacing and instant start with keyed timebase. Weighting is variable with an internal trim pot. The speed range is adjustable from 8 to 50 wpm with a control on the rear panel. Also on the rear of the unit are the tune-off-on-sidetone off switch and phono jacks for keying output and external paddle. For operation in the iambic mode an external



NEW FLAT RIBBON JUMPERS FEATURE MOLDED-ON CONNECTORS AND FACTORY TESTING

Since February, A P Products Incorporated has had a directly interchangeable, fully assembled jumper line that is a cost effective alternate to the customer assembled mass terminated flat cables. In addition, the A P jumpers feature molded-on connectors with strain reliefs and line by line probeability. Relative to cost effectiveness, the Ohio company states that it will supply two fully assembled and tested jumpers for the price of the component parts of a competitive unassembled, untested jumper. This cost advantage is possible because all manufacturing and testing is automated, and lower-cost trinary copper alloy is used as contact material for the flat cable termination.

Three basic end terminations are available – these are socket connectors, printed circuit board connectors, and card-edge connectors. Each of these termination types is offered in the five most standard widely used sizes: 20, 26, 34, 40 and 50 contacts.

With the types and sizes listed, A P offers 60 standard single end configurations and 135 double end configurations. Additionally, A P can provide daisy chain assemblies tailored to customer requirements using any mix of end termination types. Standard ribbon cable for the line is 28 awg vinyl laminated cable which is electric pink in color. A red stripe on one edge provides a means of cable orientation. Rainbow cable with a teardown feature is optionally available on single-ended assemblies.

Even though all jumpers are built complete and tested at the factory, turn around time is targeted to be only two weeks. Additionally A P offers a special 3 day turn around service, at no extra charge, when requested.

For more information contact Robert J. Gabor, A P Products Incorporated, Box 110E, Painesville OH 44077. Phone: (216) 354-2101; TWX: 810-435-2250. Direct all inquiries to Rita Mercer.

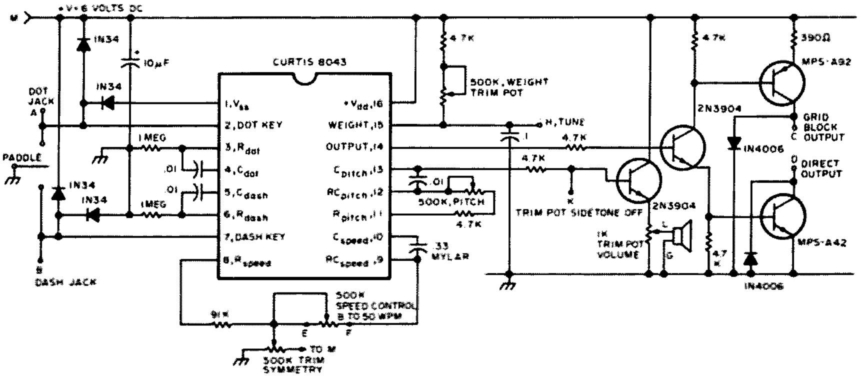


Fig. 1. Circuit diagram of MFJ CMOS-8043 electronic keyer. Jack connections: A – dot; B – dash; C – grid block output; D – direct output. Switch connections: K – sidetone off; H – tune; I – -Vcc; G – ground. Other connections: L – speaker; E, F – speed control; M – +Vcc.

squeeze-type keyer paddle is necessary. Also, operators who, like this writer, are real key thumpers, will probably prefer an external paddle with a weighted base to keep it in place during use.

Its small size, light weight and self-contained batteries should make the CMOS-8043 especially popular with campers, backpackers and DXpedition types who have learned to make every cubic inch of space and ounce of weight count. It also merits the attention of stay-at-home, fixed-station operators, whether their operating preference be traffic handling, DXing or just old-fashioned ragchewing. Priced at $39.95, the CMOS-8043 electronic keyer is available from dealers or direct from MFJ Enterprises, P.O. Box 494, Mississippi State MS 39762. ■
